A peculiar sensitization. Luppo-Cramer. *Phot. Korr.* **75**, 132-4(1939); cf. *C. A.* **30**, 4415[2] and preceding abstr.—An insolated AgI gelatin emulsion plate, after being "desilvered" with CrO_3 mixt., shows appreciably higher threshold speed (18° E.-H.) and greater contrast, on development in alk. amidol, than does a similar but uninsolated AgI plate, either treated with CrO_3 or not so treated. That this can be attributed to the sensitizing action of (persistently) adsorbed Ag ions is supported by the observation that a $AgNO_3$ treatment consisting of bathing the iodide plates in a 1% soln. for 3 min. is as effective as insolation. E. R. Bullock

Sensitization and desensitization of sensitive layers for high-energy rays. E. Schopper. *Phot. Ind.* **36**, 845 (1938); cf. *C. A.* **32**, 39[2]; **33**, 2829[1].—Optical sensitizers act very inefficiently or not at all for high-energy quanta such as x-rays, γ-rays or for corpuscular rays such as α-rays, protons or electrons. A new sensitizing action of pinakryptol yellow is described. Plates treated with this dye and exposed to β-rays *in vacuo* show a higher d. of developed grains along the tracks of these particles in the sensitive layer. W. F. Berg

Desensitization. R. Namias. *Progresso fot.* **45**, 331-5 (1938); *Phot. Abstracts* **19**, 39(1939).—Plates desensitized with pinakryptol green (I), but not with safranine (II), give an objectionable fog in caustic developers. A mixt. of a smaller amt. of I and more of II gives satisfactory results.

Mechanical properties of films. P. V. Kozlov. *Kino-Foto-Khim. Prom.* **1938**, No. 9, 28-32; *Khim. Referat. Zhur.* 2, No. 3, 130; cf. *C. A.* **33**, 8513[9].—There are 3 different regions on the stretching curve of films prepd. from cellulose ethers. The region of elastic deformation is most important for the motion-picture industry. This region of the stretching curve depends on the magnitude of the intermol. adherence of the cellulose ether complexes and, consequently, on the distance between the single chains or their regions, and on the nature of the cellulose ether. The region of plastic deformation (i. e., the sliding of the single chains in the film or their regions in relation to each other) is greater the greater the contact surface and the distance between them. The longer the chain, the greater is the possible contact surface and the greater is the work done in sliding of one chain in relation to another. The region of elastic deformation of the films with the oriented cellulose ether complexes (in the process of plastic stretching) is of secondary importance and is characterized as a "reserve" of durability. For best results the films must possess max. elastic and plastic deformability. W. R. Henn

Changes in the physicochemical properties of cinematographic films on prolonged standing. S. M. Solov'ev and Va. A. Shnaidman. *Kino-Foto.-Khim. Prom.* **1938**, No. 6, 51-6; *Khim. Referat. Zhur.* 2, No. 3, 129-30; cf. *C. A.* **32**, 2855[7].—There was but slight difference in the physicochem. properties of emulsion-coated (unprocessed) and non-coated films which were stored outdoors for 6-7 years from those not exposed to the weather. Strength decreases with increased duration of storing. Aging under thermostatic conditions had the same effect on the dynamic properties as has natural aging. A splitting of the films into layers was observed in natural aging under unfavorable atm. conditions. W. R. Henn

Medium-speed single-layer films and exposure latitude. H. Starke. *Fot. Rundschau* **76**, 312(1939).—It has been found that a certain com. single-layer film of 17/10° DIN possesses sufficient latitude to give acceptable prints of a subject of normal lighting range, exposed from 0.001 to 4 sec. R. W. Henn

Photographic plates used in astronomy. M. G. Fracastoro. *Osservazioni e mem. R. osservatorio astrofisico Arcetri Univ. Firenze* No. **57**, 57-67(1939).—Data are presented of a new panchromatic emulsion (Ferrania Suiperpavero antihalo 20/10° DIN), which is being produced in Italy and which is highly sensitized for astronomical use. Microdensitometer curves of d. plotted against wave length show a smoother curve for the new emulsion as compared with the commonly used Agfa Isopan ISS, which has more pronounced peaks and depressions, especially in the red region of the spectrum. These peaks and depressions are further analyzed by curves comparing the new emulsion with the older types under different conditions of exposure at the various wave lengths at which the maxima and minima occur. C. R. Amadeo

Evaluation of motion-picture films by semimicro testing. J. E. Gibson and C. G. Weber. *J. Soc. Motion Picture Engrs.* **32**, 105-9(1939); cf. *C. A.* **33**, 4145[3].—The article shows how the approx. quality and condition of film stored as permanent records can be detd. by tests for acidity, viscosity and residual $Na_2S_2O_3$; specimens weighing only 7 mg. each were used. These tests are recommended to archivists and librarians for detg. the condition of films in their custody, so that the necessity for making duplicates can be detd. before damage by deterioration is serious enough to be visible. J. G. Streiffert

Preparation of "magic photographs." Felix Formstecher. *Phot. Ind.* **36**, 1014-15(1938); *Phot. Abstracts* **19**, 78.—A review of the methods used for the prepn. of "magic photographs," i. e., bleached images on paper made visible by the action of some chemical or of light.

Methods of producing patterns on cloth (Freytag) **25**. Methods for prepn. of starting substances for sensitizers of quinoline series—isocyanines (Alekseeva) **10**.

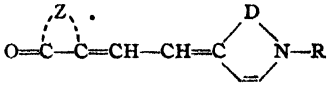
Color photography. Lothar Jakob and Bruno Wendt

to Agfa Ansco Corp.). U. S. 2,177,257, Oct. 24. A process of producing colored photographic pictures comprises exposing to light a photographic material provided with at least one emulsion layer contg. a light-sensitive Ag halide, transforming the latent image into a Ag halide image, converting the Ag halide image by an amine capable of being diazotized or an antidiazotate thereof, the compd. contg. a mercapto group, an ethinyl group or an imino group, the H atom of the group being capable of being exchanged for a metal, into an image of the corresponding org. Ag compd. and transforming the image into an azo-dye picture.

Color photography. Edwin B. Hesser and Eva L. V. Hesser (to Photocolor Corp. of America). U. S. 2,177,342, Oct. 24. A method of producing a multicolor photographic record involves exposing from the same side 2 regions of photographic film having 2 sensitive layers arranged in superposition, the first layer nearest the lens being sensitive to blue and green but not to red, the second layer being effectively sensitive to red only, one region only being exposed through a yellow filter for recording a portion of the spectrum in the first layer and another portion of the spectrum in the second layer, and the other region being exposed without any filter for recording another portion of the spectrum in the second layer of such other region.

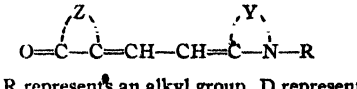
Color photography. Ernst Bauer (to Agfa Ansco Corp.). U. S. 2,177,632, Oct. 31. Color photographs are produced by a process which involves exposing to light controlled by an object to be reproduced, a 3-layer photographic element, two layers of the element comprising a color-forming development component fast to diffusion for the blue and the red picture, resp., and one layer comprising a substantive azo dye component; developing the element with an aromatic amino developer, thereby forming a Ag and a color picture in the two first-named layers in a single development step, and a Ag picture in the second-named layer, removing the undeveloped Ag salt, converting the residual Ag picture into a Ag antidiazotate picture and causing the substantive azo-dye component to couple with the silver-antidiazotate.

Color photography. Veracol Film Syndicate Ltd. and Humphrey Desmond Murray. Brit. 507,611, June 19, 1939. A light-sensitive Ag salt emulsion is developed by means of an aromatic amino developing agent and contains as a color-former a compd. of formula $X.CH{:}CH.-CH{:}CHCOCH_2CONRR'$, wherein X is an O or a S atom, R is H or an alkyl, e. g., Me, Et, Pr or higher alkyl, aralkyl e. g., benzyl, alicyclic, e. g., cyclohexyl, aryl, e. g., Ph, or azole, e. g., benzothiazole, group and R′ is also a H atom or 1 of the above groups. R and R′ may be substituted with halogen atoms or OH, alkoxy, NO_2, NH_2, substituted NH_2, Bz or phenylazo groups. Color-formers specified are furoylacetamide and the *N*-furoylacetyl derivs. of the following: monoamines and their halo and NO_2 derivs., e. g., $PhNH_2$, *p*-nitroaniline, *p*-chloroaniline, 2,5-dichloroaniline, *C*-alkylanilines and their halo and NO_2 derivs., e. g., *m*- and *p*-toluidine, 2,5-dimethylaniline, 2,3,5,6-tetramethylaniline, *C*-alkoxy and *C*-aryloxyanilines and their halo and NO_2 derivs., e. g., anisidines, phenetidines, 2,5-diethoxyaniline, *o*-phenoxyaniline, di- and polyamines, e. g., *p*-phenylenediamine, benzidine and bianisidine, α- and β-naphthylamine, *p*-aminophenylmorpholine, 2-amino-6-methylbenzothiazole and *p*-amino-*p*′-hydroxyazobenzene. Similar thiophene derivs. may be used. Developing agents specified are alkylphenylenediamines, e. g., dimethyl- and diethyl-*p*-phenylenediamines, and their derivs., alkyltolylenediamines and alkylnaphthylenediamines.



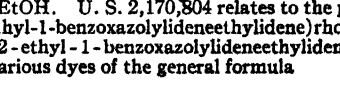
Photomechanical color process. John A. C. Yule (to Eastman Kodak Co.). U. S. 2,176,518, Oct. 17. In a photomech. process employing 3 subtractive-color coloring materials for the reproduction of a multicolored original, a method of making a color printer comprises exposing a sensitive photographic layer to one of the primary colors from the original and to a different color from the original, developing the layer, prepg. a positive image corresponding to a color from the original effectively the same as the different color, making a negative comprising the developed layer masked by the positive and printing a positive printer therefrom. Cf. *C. A.* **33**, 7226[1].

Coloring photographic images. Wm. H. Evans. U. S. 2,176,585, Oct. 17. A process of coloring a photographic image involves developing a light-exposed Ag halide type photographic emulsion, treating it without fixing in a bath which simultaneously removes the reduced Ag image and forms a latent non-Ag image capable of becoming a color image when treated with acid dyes of the type which are nondyeing to gelatin in the presence of an alkali, in the presence of an activator for the dyes such as NaOAc, removing the Ag salts in a fixing bath, and then staining the latent image with a soln. contg. NaOAc and an acid dye of the type mentioned.



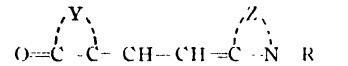
Color correction of negatives and printing plates. Wm. J. Wilkinson (50% to Miehle Printing Press and Mfg. Co.). U. S. 2,177,195, Oct. 24. A process is employed which involves making: (*a*) yellow, red and blue color-sepn. photographic negatives of a multicolor subject, (*b*) a positive photographic transparency through the yellow-sepn. negative, (*c*) a corrective photographic overlay-transparency for the yellow-sepn. negative comprising making a photographic transparency through the positive transparency and the red-sepn. negative while the two are in superposed registered relation, (*d*) correction of the yellow-sepn. negative by applying the overlay thereto and in register therewith, (*e*) a second positive photographic transparency through the red-sepn. negative, (*f*) a corrective photographic overlay-transparency for the red-sepn. negative through the second positive transparency and the blue-sepn. negative while the two are in superposed registered relation, (*g*) correction of the red-sepn. negative by applying its corrective overlay thereto and in register therewith, and (*h*) corresponding printing plates from the corrected yellow-sepn. and red-sepn. negatives and the blue-sepn. negative.

Specially sensitized photographic emulsions. Burt H. Carroll and Edward P. Davey (to Eastman Kodak Co.). U. S. 2,177,635, Oct. 31. See Can. 380,343 (*C. A.* **33**, 5308[2]).



Photographic sensitizing dyes. Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,170,803, Aug. 29. Numerous examples are given of the production of merocyanine dyes of the general formulas

and



wherein R represents an alkyl group, D represents a phenylene group, Y represents the nonmetallic atoms necessary to complete a cyclic nucleus selected from the group consisting of 5- or 6-membered heterocyclic nucleus and Z represents the nonmetallic atoms necessary to complete a rhodanine nucleus. E. g., 5-(1-ethyl-2-quinolylidene)-3-phenylrhodanine is produced by refluxing 3-phenylrhodanine with 2-iodoquinoline ethiodide and triethylamine and abs. EtOH. U. S. 2,170,804 relates to the production of 5-(2-ethyl-1-benzoxazolylideneethylidene)rhodanine, 3-ethyl-5-(2-ethyl-1-benzoxazolylideneethylidene) rhodanine and various dyes of the general formula

wherein A represents O or S, R represents an alkyl group, Y represents the nonmetallic atoms necessary to complete a benzoxazole nucleus and Z represents the nonmetallic atoms necessary to complete a five-membered heterocyclic nucleus containing a nuclear N and a nuclear S atom, by a

process which may comprise treating, in the presence of a trialkylamine condensing agent, a 1-(β-anilinovinyl)benzoxazole alkyl quaternary salt with a five-membered heterocyclic compd. contg. a reactive nuclear methylene group adjacent to a nuclear carbonyl group or a six-membered heterocyclic compd. contg. a reactive nuclear methylene group adjacent to a nuclear carbonyl group. U. S. 2,170,805 relates to photographic gelatino-Ag halide emulsions sensitized with such dyes. U. S. 2,170,806 relates to the production of 1-(2-ethyl-1-benzoxazolylideneethylidene)-2(1)-thianaphthenone, 1-(3-methyl-2-thiazolinylideneethylidene)-2(1)-thionaphthenone, and various dyes of the general formulas

and

wherein D represents a vinylene or phenylene group, R represents an alkyl group, Y represents the non-metallic atoms necessary to complete a 2(1)-thianaphthenone nucleus and Z represents the nonmetallic atoms necessary to complete a 5- or 6-membered heterocyclic nucleus. U. S. 2,170,807 relates to the production of 5-(2-ethyl-1-benzothiazolylideneethylidene)-2,4,6-triketohexahydropyrimidine and various merocarbocyanine dyes derived from barbituric acids.

2-Alkylhexahydrobenzo-thiazoles and -selenazoles. Walter Zeh (to Agfa Ansco Corp.). U. S. 2,173,491, Sept. 19. See Can. 377,534 (*C. A.* **33**, 2148[7]).

Photographic sound track on colored film. Charles F. Jones (25% each to J. D. Grant and C. W. Durbrow). U. S. 2,176,303, Oct. 17. A method of reproducing a photographic sound track on a film comprising a plurality of superposed differently sensitized emulsion strata involves: printing the sound track to the film using a printing light to which but one of the strata is sensitive; completely exposing the sound track areas in the other of the strata to light to which they are sensitive; developing the images thereby obtained; bleaching the images; exposing the film to light; redeveloping the film; and coloring the resulting sound track image in the first stratum.

Polarizing layers suitable for use in photography. Gustav Wilmanns and Wilhelm Schneider (to Agfa Ansco Corp.). U. S. 2,176,516, Oct. 17. A polarizing body comprises a solid suspending medium such as a cellulose ester compn. and particles which are addn. compds. constituted of a heterocyclic N compd. contg. in its mol. only one heterocyclic N nucleus which has either 5 or 6 ring members, such as 2,5-diphenyloxazole, and a metal salt, such as $FeCl_3$ or $CuCl_2$, or Br or I, these particles being embedded in the suspending medium with their polarizing axes substantially parallel.

Photographic printing on lenticular films. John Eggert and Gerd Heymer (to I. G. Farbenind. A.-G.). U. S. 2,177,417, Oct. 24. Various optical and operative details.

Blue-print paper and cloth. John Holden (to Keuffel & Esser Co.). U. S. reissue 21,240, Oct. 17. A reissue of original patent No. 2,158,422 (*C. A.* **33**, 6712[9]).

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

Lead suboxide. L. Leighton Bircumshaw and Ivan Harris. *J. Chem. Soc.* **1939**, 1637-9. The decompn. of PbC_2O_4 at 0.01 mm. at temps. of 310° to 470° is expressed by $3PbC_2O_4 = Pb + 2PbO + 4CO_2 + 2CO$, as detd. by analysis of the gases evolved. The residue of the decompn. is a mixt. of Pb and red tetragonal PbO rather than the suboxide, Pb_2O. This was confirmed by x-ray diffraction patterns and by elec. cond., which for the decompn. residue was 10,000 times the value for PbO. A. F.

Some new observations on hydrazine. C. H. Bamford. *Trans. Faraday Soc.* **35**, 1239-46(1939).—Pure hydrazine vapor when sparked at 100° explodes and a yellow flame accompanies the decompn. The products are NH_3, H_2 and N_2, the NH_3 and H_2 being approx. equiv. The explosion has the usual lower and upper pressure limits. The heterogeneous decompn. at a quartz surface in the presence of NO was also studied and as a result it is suggested that the primary step in the decompn. is the dissocn. into 2 NH_2. Victor R. Deitz

Evidence for existence of a selenium iodide. James D. McCullough. *J. Am. Chem. Soc.* **61**, 3401-2(1939).—Absorption spectra give strong evidence in favor of compd. formation between selenium and iodine in CS_2. Soly. data give quant. measurements of the equil. between Se and I in CCl_4. These data indicate the presence of a compd. having the formula Se_nI_2 with n undetd. A. B. Garrett

The preparation of sulfamic acid by the hydroxylamine-sulfur dioxide reaction. H. H. Sisler and L. F. Audrieth. *J. Am. Chem. Soc.* **61**, 3389-91(1939).—The yield of sulfamic acid from the reaction of hydroxylamine salts with SO_2 is greatly increased and the time required for the reaction decreased by operating under pressure. This is also true of the acetoxime reaction. The reaction is inhibited by excessive concns of hydronium ions. A mechanism for the reaction is proposed involving coördination between the hydroxylamine mol. and SO_2 with subsequent rearrangement to sulfamic acid. A. B. Garrett

The action of liquid ammonia upon sulfur trioxide addition compounds. H. H. Sisler and L. F. Audrieth. *J. Am. Chem. Soc.* **61**, 3392-3(1939). The reactions of NH_3 with $ClSO_3H$ and $ClSO_3Na$ are ammonolytic in character, involving replacement of a negative constituent by the NH_2 group and leading to the formation of the sulfamate. The same mechanism also characterizes the reaction of NH_3 on addn. compds. of SO_3 with pyridine, dimethylaniline and dioxane. A. B. Garrett

Acetometallates. II. Acetozincate. Alexander Lehrman and Philip Skell. *J. Am. Chem. Soc.* **61**, 3340-2 (1939).—The liquidus curve of the binary system zinc acetate–sodium acetate was detd. and the compd. $2NaC_2H_3O_2.Zn(C_2H_3O_2)_2$ or $Na_2Zn(C_2H_3O_2)_4$ shown to exist. The analogy between this compd. and $Na_2Zn(OH)_4$ is discussed. A. B. Garrett

Kinetics of complex formation in nonaqueous solutions in connection with electrical conductivity. II. E. Ya. Gorenbein. *J. Gen. Chem.* (U. S. S. R.) **9**, 1369-72 (1939).—See *C. A.* **33**, 5267[8]. E. J. C.

7—ANALYTICAL CHEMISTRY

W. T. HALL

X-ray diffraction applied to chemical analysis. Wheeler P. Davey. *J. Applied Phys.* **10**, 820-30(1939).—A review. E. H.

Qualitative spectrographic analysis in the arc with graphite electrodes. W. C. Pierce, O. Ramirez Torres and W. W. Marshall. *Ind. Eng. Chem., Anal. Ed.* **12**, 41 5(1940); cf. *C. A.* **33**, 4153⁸.—The methods and app. for qual. spectrographic analysis with a d. c. arc are described and from comparative studies the conclusion is drawn that anode excitation is generally preferable. The factors affecting the sensitivity are discussed and sensitivity data are given for typical analyses in which traces of elements in materials such as dolomite, silicon, pig iron and com. Pb are detected. W. T. H.

Direct chemical rapid analysis with the mercury dropping electrode. J. Bocke and H. van Suchtelen. *Z. Elektrochem.* **45**, 753-6(1939).— The methods used for working with the moving Hg electrode are described and compared with respect to the time requirements. Considerable time can be saved if the current is registered for the indication of the half-wave potential. Two methods of arriving at these values are outlined. W. T. H.

A vapor pressure method for the estimation of volatile solvents. Charles E. Couchman and Wilmer H. Schulze. *J. Ind. Hyg. Toxicol.* **21**, 256 63(1939).— The vapor-laden air is drawn through a trap immersed in a dry-ice and acetone mixt., which freezes out the vapor. The trap is then evacuated while in the freezing mixt. and the pressure of the compd in the vaporous stage is measured at room temp. Diagrams of app. are given. A. L. Elder

A vapor pressure method for determination of the concentration of some organic solvents in air. Kingsley Kay, Geo. M. Reece and Philip Drinker. *J. Ind. Hyg. Toxicol.* 21, 264 9(1939). Org. solvents in air were frozen out in a 9-ft. glass coil. The partial pressure of the solvent can be accurately estd. Water is kept in the coil and its vapor pressure subtracted from the readings. Accuracy of ±5% is claimed. A. L. Elder

A new vapor pressure instrument for determining organic solvents in air. Leslie Silverman, Geo. M. Reece and Philip Drinker. *J. Ind. Hyg. Toxicol.* **21**, 270 8 (1939).— The instrument consists of 2 identical 65-cc brass cells partially filled with bronze balls and provided with inlet and outlet valves. The contaminated atm. is drawn through one cell and frozen out. All valves are then closed, the instrument is warmed in a water bath, connected to a manometer and the pressure read. Diagrams of app. are shown. A. L. Elder

Quantitative absorption spectrophotometry—an internal control method. J. S. Owens. *Ind. Eng. Chem., Anal. Ed.* **11**, 643 6(1939). Absorption spectra of a comparison material and of some material whose concn. is to be detd. by the amt. of its absorption at a given wave length are photographed on the same photographic plate. The intensity ratio of wave lengths, preferably in the peak of the absorption band, of the comparison and second substance is detd., from which extinction coeffs. (k) are calcd. These coeffs. are converted to concn. by an empirical analytical curve. The method was applied for detg. the monomer content (bands at 2910 A. and 2830 A.) in partially polymerized styrene. The accuracy in detg. k in the range 0.08 to 0.12 from a single spectrum was $k \pm 0.006$ for monostyrene. The method was used for the range from 0.58 to 100% monomer content. L. W. S.

Computing titration blanks. Francis W. Glaze. *Ind. Eng. Chem., Anal. Ed.* **12**, 14 15(1940).—In making precise detns. by titration it is customary to allow for the quantity of reagent which would be required to give the end point when none of the substance titrated is really present. This is commonly done by carrying out a "blank" detn. in exactly the same way that the analysis is made. Park, *C. A.* **30**, 1322⁷, has recommended the computation of the value of the blank from a series of detns. with varying quantities of the substance in question from which a plot can be made with the quantities of reagent used as ordinates and the actual content of the solns. tested as abscissas. From this plotted line the value at O concn. can be detd. by extrapolation. This method is good if the results of the expts. fall in a straight line, which is seldom the case. It seems preferable, therefore, to calc. the slope of the line from a series of expts. by the method of least squares. This procedure is explained in connection with the titration of Zn^{++} by ferrocyanide and of B_2O_3 with $Ba(OH)_2$. W. T. H.

Photelometric study of the lead-dithizone system at 610 millimicrons. Charles L. Guettel. *Ind. Eng. Chem., Anal. Ed.* **11**, 639-40(1939).— The results of expts. show that 15 ml. of soln. contg. 12 mg. dithizone per l. is appropriate for detg. 15-50 γ of Pb. For lower Pb concns. it is better to use 15 ml. of dithizone soln. contg. 4 mg. per l. The standard Pb solns. were prepd. as outlined by the Assoc. Official Agr. Chemists but the procedure for making the test was modified somewhat. W. T. H.

Calibration and use of the gas interferometer. F. A. Patty. *J. Ind. Hyg. Toxicol.* **21**, 469-74(1939).—A portable gas interferometer is recommended for the analysis of gas contg. org. vapors. Unit refractivity changes for 40 solvents are given. A. L. Elder

Use of interferometer for two-component mixtures. C. C. Harrold and L. E. Gordon. *J. Ind. Hyg. Toxicol.* **21**, 191-7(1939). CO_2 and moisture-free air are used in the reference standard. Aviation gasoline, CCl_4 and mixts. were studied. A. L. Elder

Mercaptobenzimidazole as an analytical reagent. M. Kuraš. *Collection Czech. Chem. Commun.* **11**, 321–4 (1939).— See *C. A.* **33**, 7233³. H. Game

Indicators. A. Voigt. *Oberflachentech.* **16**, 215–16 (1939).— A review with 8 references. M. Hartenheim

Mercury iodocyanide as acid indicator for organic compounds, particularly for ring nitro compounds. Langhans. *Nitrocellulose* **10**, 163 5, 184–5, 207 8(1939). A soln. of 12.6 g. $Hg(CN)_2$ in 200 cc. H_2O and 6.3 g. I in 12.6 g. KI in 200 cc. H_2O gives immediate sepn. of HgI_2 with the slightest trace of acid. Acidity tests with hundreds of substances are shown. E. M. Symmes

Amperometric (polarometric) titrations. I. The amperometric titration of lead with dichromate or chromate. I. M. Kolthoff and Yu-Djai Pan. *J. Am. Chem. Soc.* **61**, 3402 9(1939). Amperometric titrations are those in which the current which passes between 2 suitable electrodes at a const. e. m. f. is measured. Only one or both of the electrodes may be placed in the titration medium. The end point is found as the point of intersection of 2 lines giving the change of the current before and after the equivalence point. The principle underlying this type of titration is discussed as well as the application to the titration of Pb^{++}. Even 0.001 *M* Pb solns. can be titrated with a high degree of accuracy. Pb can be titrated amperometrically in the presence of large amts. of Ba when the soln. is slightly acid with $HClO_4$. A. B. Garrett

Test for magnesium with *p*-nitrobenzeneazoresorcinol. Effect of diverse ions. J. P. Mehlig and K. R. Johnson. *Ind. Eng. Chem., Anal. Ed.* **12**, 30-1(1940).—Suitsu and Okuna (*C. A.* **20**, 300) showed that 0.002 mg. of Mg can be detected by the formation of a sky-blue lake with *p*-nitrobenzeneazoresorcinol. This has been called the S. and O. reagent. Other chemists have testified concerning the sensitivity of the test and shown that quite a no. of ions interfere. The purpose of the present work was to make a further study of interference. The effect of 44 other ions was studied. Although many of the cations of the first 3 groups in the usual qual. scheme interfere, they are easily removed by conventional methods. Al, Ba, Ca and Sr, which cause so much trouble when the attempt is made to detect Mg^{++} by forming $MgNH_4PO_4.6H_2O$, do not interfere at all. Very few anions cause trouble (As-

O_4^{---}, CrO_4^{--}, MnO_4^{-}) and although the test is not specific, it is satisfactory, efficient and very useful. W. T. H.

Manganese and chromium in steel. Modified persulfate-arsenite method. R. P. Forsyth and W. F. Barfoot. *Ind. Eng. Chem., Anal. Ed.* **11**, 625(1939).— The persulfate method for detg. Mn consists in treating the acid soln. with excess persulfate in the presence of Ag^+, the excess persulfate is destroyed by boiling, a measured vol. of standard arsenite is added and the excess titrated with $KMnO_4$. In this last reaction the As is oxidized completely to the quinquevalent state but the MnO_4^- is reduced somewhat indefinitely so that the soln. has to be standardized empirically. If 3 drops of 0.01 *M* OsO_4 is added to the soln., however, the MnO_4^- is reduced completely to Mn^{++} and the $KMnO_4$ can be standardized against $Na_2C_2O_4$. It is important that all excess persulfate be destroyed, which requires boiling for about 4 min. If Cr is present it is detd. with the Mn, then after the $KMnO_4$ titration, the Cr and Mn can be oxidized again, the resulting MnO_4 reduced, the Ag^+ pptd. with HCl and then the Cr detd. by itself. W. T. H.

Separation and colorimetric determination of rhenium and molybdenum. James I. Hoffman and G. E. F. Lundell. *J. Research Natl. Bur. Standards* **23**, 497–508 (1939).—For detg. either Re or Mo when only one of these elements is present, use can be made of the fact that a colored soln. is formed by the addn. of CNS^- + $SnCl_2$ but the reddish colors are so similar that the colorimetric detn. fails when both Re and Mo are present. If a soln. contg. perrhenate and molybdate in 6 *N* HCl is shaken with ether, most of the Mo can be made to pass into the ethereal layer by repeated treatments and nearly all of the Re will remain in the aq. layer. This serves to effect a fairly good sepn. but allowance must be made for the small quantities of both Re and Mo which go the wrong way. The ether sepn. seems to go better in the presence of a little $FeCl_3$. Then, if the aq. ext. is dild. to make the soln. 0.17 *N* in HCl a double extn. with KCNS + Hg + ether serves to remove the last traces of Mo in the ether where it is detd. colorimetrically and the quantity of Mo found should be added to that found in the original ether ext. The ethereal soln. now obtained contains the Re probably as $ReO(CNS)_4$ and the content of this red compd. can be detd. by colorimetric comparison with standards. After the removal of the ether from the original ether ext., which contains most of the Mo and very little Re, treatment with KCNS + Hg + ether in 2.5 *N* HCl serves to ext. the Mo as complex thiocyanate which has a blood-red color and is suitable for colorimetric comparison. Some authorities think that the Mo is not entirely in the trivalent state. The aq. layer will now contain a little Re which is detd. colorimetrically after reduction with KCNS + $SnCl_2$ + ether. The procedure can be shortened in many cases It is intended for the analysis of solns. contg. not more than 10 mg. of either element. Cr, Pt, Rh, V and W interfere somewhat and Cu, Au, Pd, Se and Te contaminate the Hg used so that it must be purified before it is used again. W. T. H.

The thiocyanate reaction of molybdenum. Yasumitu Uzumasa and Ken-iti Doi. *Bull. Chem. Soc. Japan* **14**, 337–43(1939).—By means of photoelec. studies, the conclusion is drawn that in the thiocyanate test, the Mo is reduced from molybdate to the quinquevalent state, possibly to $K_3[MoO(SCN)_5]$. To obtain the max. red color, the acid content should lie between 5 and 6% and it is best to add the KCNS reagent before the $SnCl_2$. If these conditions are not maintained, there is danger of colored Mo compds. being formed of other valence. W. T. H.

Determination of molybdenum in cast iron and steel. Calvin Sterling and W. P. Spuhr. *Ind. Eng. Chem., Anal. Ed.* **12**, 33–4(1940).—The proposed method consists in pptg. the Mo with α-benzoinoxime (cf. Knowles, *C. A.* **26**, 5273), dissolving the filtered and washed ppt. in aq. NH_3, filtering and pptg. the Mo as $PbMoO_4$ which is heated and weighed. The results of 14 analyses with samples contg. 0.2–0.70% Mo were excellent. W. T. H.

Determination of active oxygen in alkaline peroxides. I. Mario Sartori. *Ann. chim. applicata* **29**, 381–6 (1939).—Owing to the importance of the detn. of active O in alk. peroxides in the regeneration of air, various known methods were evaluated. The volumetric methods of Rupp (*Arch. Pharm.* **240**, 437(1902)) and of Bosshard and Furrer (*C. A.* **18**, 2658) were found to give low results, owing to some escape of O_2. The methods of Archbutt (*Analyst* **20**, 3(1895)) and of Desgrez and Labat (*C. A.* **16**, 541) were found satisfactory. II. **Determination of the activity of alkaline peroxides in the regeneration of air** *Ibid.* 386–91.— An app. has been developed which measures the O_2 evolved from a given amt. of peroxide when a given vol. of a mixt. of gases which closely approximates exhaled air is passed through the sample. A. W. C.

Some measuring methods for detecting O_2 in molten steel. Mituzaburō Umezawa. *Tetsu-to-Hagane* **25**, 842–50(1939).—(1) The change of O_2 in molten steel of acid open-hearth melt can be estd. by the change of CaO content in the slag. (2) The change of O_2 in molten steel can be calcd. by the change of deoxidizing elements, such as C, Si and Mn. (3) The change of O_2 in molten steel can be estd. from an accurate computation for the boundary conditions such as O_2 before deoxidation, oxidation by flame and bed, amt. of O_2 in solidified steels, etc. M. I.

Bromoiodometric determinations. XI. Is the fluorescein reaction of Hahn specific for bromine? J. H. van der Meulen. *Chem. Weekblad* **36**, 702–5(1939); cf. *C. A.* **33**, 6750⁴.—The method of Hahn (*C. A.* **29**, 5381³) for the detn. of small amts. of Br is not specific for Br since I will also give a fluorescent compd. with fluorescein. The red color which is developed with Br is unstable to direct sunlight or bright daylight. A method is described by means of which it is possible to distinguish between Br and I. Felix Saunders

The color reactions of sulfur chloride, S_2Cl_2, and sulfur dichloride, SCl_2, with *o*-tolidine and their analytical applications. Gustaf Holst. *Ber.* **72B**, 1909–13(1939).—A soln. of 0.010 *M* S_2Cl_2 in pure CCl_4 gives with 5 times as much of 0.010 *M* *o*-tolidine in a mixt. of equal vols. CCl_4 and EtOH an intense red color which is fairly stable in the dark. An excess of the *o*-tolidine soln. is necessary to prevent pptn. Neither $SOCl_2$ nor SO_2Cl_2 gives any color with *o*-tolidine and the color produced with SCl_2 is much less intense. This reaction can be used for detg. small quantities of S_2Cl_2 and, when a suitable filter is used, also for the analysis of mixts. of S_2Cl_2 and SCl_2. W. T. H.

Possible errors in determining cassiterite by reduction with a zinc plate. E. V. Kopchenova. *Zolotaya Prom* **11**, No. 6, 30–3(1939).—The detn. of cassiterite by reducing it to Sn with HCl on a Zn plate may give inaccurate results because other compds. such as oxides, carbonates, and sulfates of Pb, Bi and Cu also form coatings on the surface. To avoid errors the coating is removed, dissolved in a few drops of concd. HCl on a watch glass, a drop of the acid soln. is placed on a filter paper and tested for Sn with a drop of an aq. soln. of cacotheline. A violet coloration indicates Sn. B. Z. Kamich

New method of analyzing cyanide slimes. E. A. Marenkov. *Zolotaya Prom.* **11**, No. 7, 30–1(1939).— Heat a 1-g. sample of cyanide slimes with 50–80 ml. concd. HNO_3 on a sand bath for 15–20 min., dil. with hot water to 150–200 ml., filter, wash the residue with water contg. 1–2 drops of HNO_3 and det. the Ag in the filtrate as AgCl. Heat the residue with 50–60 ml. of aqua regia on a sand bath, evap. with HCl until all HNO_3 is expelled (not to dryness), dil. with hot water to 150–180 ml., filter, heat and ppt. the Au with a hot satd. soln. of hydrazine-HCl. B. Z. Kamich

Microdetermination of iron with the silver reductor. Sylvan M. Edmonds and Nathan Birnbaum. *Ind. Eng. Chem., Anal. Ed.* **12**, 60–1(1940).—The micromethod described is a direct adaptation of the macroprocedure of Walden, Hammett and Edmonds (*C. A.* **28**, 1953⁷) with the scale of app. reduced in proportion to the abs. amt. of Fe present. Resultsa ccurate to 6 γ were obtained with samples of material ranging from 0.69 to 2.75 mg. W. T. H.

Effects and distribution of mercury. XXIX. Film

phenomena and the microchemical determination of mercury. Alfred Stock. *Ber.* **72B**, 1844–57(1939); cf. *C. A.* **32**, 3816[8], 4099[9].—Neutral aq. solns. contg. about 1 γ of Hg in 10 ml. of soln. lose almost all of the Hg when the total vol. of soln. is reduced from 10 ml. to 5 ml. at room temp. The expts. here described can be explained best by assuming that a thin, unimol. film is formed on the surface of the liquid solvent. The addn. of acid- or water-sol. salt prevents the loss of Hg by evapn. Probably the relatively fast evapn. of metallic Hg through layers of water, benzene, etc., can be explained similarly. Dil. solns. of Hg salt in Pt also appear to form on the surface of the Pt a film which is not easily removed by washing with water. Such films do not appear to form on glass or quartz surfaces but parts of the living organism (heart, kidney etc.) behave like Pt; some of the adsorbed Hg salt can be removed by washing with HCl. Dil. solns. of Hg salt kept in glass or quartz containers lose appreciable quantities of Hg on standing but the cause of the adsorption of the Hg by the glass does not appear to be of nonchem. nature. The error is greater if the surface of the glass has been scratched or etched. This effect may be the cause of serious error in microchem. work. Acids may cause the removal of a part of this Hg salt and in some cases too much Hg may be found. In the analysis of expired air from mouths contg. amalgam fillings, practically all the Hg was condensed together with the moisture when the expired air was cooled to 0°. It is suggested that it is likely that the expired air may contain a little HCl which dissolves in the water vapor and a similar explanation may account for the Hg content of rain through air which contains only minute traces of Hg vapor. W. T. H. 1 2 3 4

Rapid microdetermination of nitrogen in mixtures with rare gases. J. A. M. van Liempt and W. van Wijk. *Rec. trav. chim.* **58**, 964–72(1939)(in German); cf. *C. A.* **31**, 7457[3,4]. With the app. described the N content of a mixt. of N_2 and rare gases can be detd. in 10 min. The N is absorbed by liquid Li; the accuracy of the detn. is ±0.2% N. The smallest sample which can be analyzed is 1 ml. at 1 atm. John E. Vance 5

Organo-microanalysis. VIII. Determination of carbon and hydrogen. Syusaku Sakamoto. *J. Pharm. Soc. Japan* **59**, 623–31(1939); cf. *C. A.* **33**, 1993[4].—A review. **IX Volumetric analysis of sulfur.** *Ibid.* 631–4.—A review. F. I. Nakamura 6

Accuracy and precision of microanalytical determination of carbon and hydrogen. A statistical study. Francis W. Power. *Ind. Eng. Chem., Anal. Ed.* **11**, 660–73(1939).—A study of 349 microanalyses of approx. 200 pure compds. by 23 experienced analysts shows an over-all precision of 2.9 parts per 1000 of C and 22 parts per 1000 of H. Both elements are detd. slightly too high, the error in C being probably significant and that in H probably not. The outside tolerances for H agree well with those commonly accepted; those for C are somewhat wider. A description of the statistical methods used is included, as well as some recommendations, based on the statistical findings, for improving the reliability of C-H analyses. T. H. D. 7

Analysis of organic materials for traces of metallic impurities. T. M. Hess, J. S. Owens and L. G. Reinhardt. *Ind. Eng. Chem., Anal. Ed.* **11**, 646–9(1939).—The spectroanalytical detection of traces of Al, Ca, Cu, Fe, Pb, Mg, Mn, Ni, Sr, Sn and Zn in cellulose derivs., synthetic resins, pharmaceuticals, dyes and biol. tissues or fluids is described at considerable length. The org. material was first oxidized in spectroscopically pure HNO_3, H_2SO_4 and $HClO_4$. The internal control method of analysis was used and photometric measurements were made of the relative intensities of the test elements and of the control elements which were introduced into each sample to a known extent. Considerable time is saved and results are obtained with little difficulty in detg. small contents of material which would be hard to det. accurately by the usual chem. methods of analysis. W. T. H. 8 9

Qualitative test for oxygen in organic compounds. David Davidson. *Ind. Eng. Chem., Anal. Ed.* **12**, 40–1 (1940).—Solid $Fe(CNS)_3$ is insol. in liquid hydrocarbons and their halogen derivs. but is sol. in the widest variety of compds. contg. O. To carry out a test for O, take 1 g. of $FeCl_3$ and 1 g. of KCNS in sep. containers. Dissolve each salt in 10 ml. of MeOH, mix and filter off the KCl ppt. Drench filter paper with the filtrate and dry in the air. More than 1 dipping may be required to get a greenish reflex like that of fuchsine crystals. Moisten a square of this paper with a few drops of the liquid to be tested. A pos. test is indicated by the formation of a deep wine-colored soln. Test solids by dissolving them first in hydrocarbon or hydrocarbon deriv. W. T. H. 10

Determination of sulfur in organic compounds. New microchemical method. E. W. D. Huffman. *Ind. Eng. Chem., Anal. Ed.* **12**, 53–8(1940).—When compds. contg. no other elements than C, H, O and S are burned in a combustion tube contg. Ag, good results for C and H are obtained and all S is retained as Ag_2SO_4. If the Ag, more or less covered with sulfate, is placed in a soln. contg. dil. isopropyl alc. and a little $MgSO_4$, then the passage of an elec. current through the hot soln. will cause deposition of Ag on the cathode and the deposited Ag is equivalent to the S. Care must be taken in carrying out the analysis to avoid oxidation but the results of about 55 analyses show that excellent results can be obtained. W. T. H. 11

The volumetric determination of ethyl alcohol. Radim Sigmund. *Chem. Listy* **33**, 325–8(1939)(German summary).—Into a special flask consisting of 2 100-cc. vessels connected with a narrow graduated cylinder, place 100 cc. of the unknown EtOH-gasoline mixt., overlay this with 100 cc. of a satd. NaCl aq. soln., shake the mixt. for 3 min., and after the liquids have sepd., read the new vol. of the NaCl soln. on the graduated cylinder. Because the total vol. of the EtOH-NaCl soln. is smaller than the vols. of the sep. EtOH and NaCl fractions, the usual detns. were too low. After the NaCl soln. is mixed with the EtOH-gasoline mixt., the total vol. of both solns. is also diminished. With the equation of Šťastný (*C. A.* **28**, 4831[6]) prep. a table which corrects the vols. of EtOH for their shrinkage in the NaCl soln. and gives correct values for prepd. mixts. Frank Maresh 12

Titrimetric procedure for the estimation of resin acid in addition to fatty acid. B. Stempel. *Pharm. Zentralhalle* **80**, 617–19(1939).—Dissolve 2–4 g. of the sample in 50–100 cc. xylene, add 0.25–0.5 cc. HCl (1.19) in app. for H_2O estn. and distil with a small flame and open cock. Increase heat gradually until HCl drops reach the upper end of the riser, close the cock and drive the HCl over with a larger flame till no more acid flows from the tube. After cooling and adding neutral alc. titrate with 0.5 *N* KOH (phenolphthalein or alkali blue 6B). W. O. E. 13

Method for determining glutamine in plant tissues. Geo. W. Pucher and Hubert B. Vickery. *Ind. Eng. Chem., Anal. Ed.* **12**, 27–9(1940).—The usual method for detg. glutamine is based upon the complete hydrolysis of this rather unstable amide by heating for 2 hrs. at 100° and pH 6 to 7. The NH_3 thus formed is a measure of the amido N present but, unfortunately, there are other plant components which will liberate NH_3 under the same conditions. When glutamine is hydrolyzed nearly 90% of it is converted into pyrrolidonecarboxylic acid which is a relatively strong imino acid which can be extd. completely by EtOAc from aq. solns. buffered in the range pH 2 to 3. Moreover, it is easily hydrolyzed to glutamic acid when heated for a short time with dil. mineral acid. The increase in amino N after this acid hydrolysis is equiv. to the amide N of the glutamine from which the pyrrolidone carboxylic acid was derived. From these facts a satisfactory scheme of analysis is proposed which is not, to be sure, meant to be a substitute for the convenient and accurate amide hydrolysis method. It is, however, a more sp. means of estg. glutamine and will be found useful for the detn. of small quantities or in unfavorable conditions such as in the presence of aspargine or other substances that might interfere with the simpler hydrolytic method. W. T. H. 14

Harmlessness of const.-boiling 72% $HClO_4$ (Dietz) 24.

Decompn. of cassiterite by fusion with borax and some details of its complete chemical analysis (Borneman-Starynkevich) 8.

Determining hydrocyanic acid in gas mixtures such as air. Robert W. McAllister (to Mine Safety Appliances Co.). U. S. 2,176,462, Oct. 17. A method of detg. HCN involves passing a volume of the gas mixt. through a uniform column of a granular adsorptive material such as alumina gel impregnated with a color-forming substance such as a benzidine acetate-cupric acetate soln. which is sensitive to HCN and noting the length of travel of coloration in the column, which is proportional to the content of HCN in the gas mixt.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Part taken by close packing of crystals in the diffusion of helium. E. K. Gerling. *Compt. rend. acad. sci. U. R. S. S.* **24**, 274-7(1939)(in English).—Helium losses of minerals are explained by the loose structures of feldspars, nephelites, mica, most amphiboles and pyroxenes, etc. The closeness of the packing being a detg. factor in He loss, it must be taken into consideration in age calcns. by the He method. 6 references. A. H. Krappe

Crystallographic investigation of artificial mullite. D. P. Grigor'ev and I. I. Shafranovskiĭ. *Compt. rend. acad. sci. U. R. S. S.* **23**, 933-4(1939)(in English).—A specimen of mullite obtained by the method of Ginzberg (cf. *C. A.* **32**, 8719[9]) was subjected to goniometric and optical crystal analysis. n_g = 1.657, n_p = 1.644; the small deviations from the results of Bowen and Greig (cf. *C. A.* **18**, 2587) are probably due to the presence of impurities. A goniometric study gave the following values for the angles: (1)(110).(110) = 90°52′; (2)(110) (110) = 89°08′, as compared with 90°47′ and 89°13′ found by Bowen and Greig. 3 references. A. H. Krappe

Crystallography of aramayoite. Harry Berman and C. W. Wolfe. *Mineralog. Mag.* **25**, 466-73(1939); cf. Spencer, *C. A.* **21**, 2241, and Yardley, *Ibid* Measurements of recently discovered better developed crystals of aramayoite from the type locality give $a : b : c$ = 0.8753 : 1 : 0.9406, and a = 7.76, b = 8.79, c = 8.34 A., α 100°22′, β 90°00′, γ 103°54′, with $6Ag(Sb,Bi)S_2$ in the unit cell, which is therefore 3 times as large as the cell detd. by Yardley. C. A. Silberrad

Decomposition of cassiterite by fusion with borax and some details of its complete chemical analysis. I. D. Borneman-Starynkevich. *Compt. rend. acad. sci. U. R. S. S.* **24**, 353-6(1939)(in English).—Fusion of cassiterite with borax led to a series of reactions the last of which is expressed by the formula $NaBF_4 + H_2SO_4 = BF_3 + HF + NaHSO_4$. The remaining fused Na pyrosulfate contains all the components of cassiterite; it dissolves when treated with tartaric acid. A *spectroscopic analysis* shows the presence of Sn, Si, Ti, Zr, Cb, Ta, Fe and Mn. Detn. of Sn and the other components is described in detail. 6 references. A. H. Krappe

Mineralogy of the Tikhvin bauxites. E. P. Levando and N. A. Adamova. *Mém. soc. russe minéral.* **67**, No. 1, 74-80(1938); *Khim. Referat. Zhur.* **2**, No. 4, 37(1939).—By mech. and chem. treatment of the bauxite samples of the Tikhvin region, there were obtained fine, opaque, white, isotropic grains with n = 1.647 ± 0.002. The sepd. substance is $Al_2O_3.H_2O$ with small admixts. of SiO_2, Ti and Fe and with a somewhat larger amt. of water than called for by the formula. On the basis of the chem. and optical studies, as well as from a comparison with the French bauxites, the mineral can be regarded as a non-cryst. hydrated Al_2O_3 of the böhmite type which is formed as a result of aging of the gel-like substance. W. R. H.

Tektites and silica glass. L. J. Spencer. *Mineralog. Mag.* **25**, 425-40(1939).—All available analyses of tektites and similar occurrences with d. and n (36 in all) are tabulated and compared, d. and n being plotted against SiO_2 content (68-80%). The nature and manner of occurrence of the silica glass found in the Libyan desert are then discussed. Two closely agreeing analyses average SiO_2 98.20, TiO_2 0.23, Al_2O_3 0.70, Fe_2O_3 0.53, FeO 0.24, NiO 0.02, MgO 0.01, CaO 0.30, Na_2O 0.33, K_2O 0.02, H_2O+ 0.03, H_2O- 0.03. Including traces revealed by spectroscopic analysis 22 elements have been detected in the glass, but no clue as to the origin has been found. 49 references. C. A. Silberrad

Classification of some magnesium silicates and their alumino analogs. N. E. Efremov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 287-9(1939)(in English).—On the basis of observations on clay deposits in Russia the following classification is proposed: (1) α montmorillonite, α sepiolite, (2) β montmorillonite, β sepiolite, (3) γ montmorillonite, γ sepiolite, (4) δ montmorillonite, δ sepiolite, (5) ϵ montmorillonite and ϵ sepiolite. 11 references. A. H. Krappe

Investigation of the serpentine region of Northern Caucasus. N. E. Efremov. *Bull. acad. sci. U. R. S. S., Sér. géol.* **1938**, No. 1, 107-29; *Khim. Referat. Zhur.* **2**, No. 4, 39(1939).—The serpentine minerals of Northern Caucasus originated mainly from saxonites; the age of these ultrafundamental intrusions is Permocarboniferous Many have a compn. which differs greatly from the commonly accepted formula by excessive amts. of MgO and H_2O. Two branches can be noted among the serpentine minerals: one in which are observed an increasing role of SiO_2 toward MgO and changes from serpentine through picrolite to talc with a change of the MgO SiO_2 ratio from 1.5 to 0.75, and a 2nd, in which this ratio increases from 1.5 to 2.00. Variations of the content of the main oxides in serpentines indicate that the chem. constitution changes from talc through picrolite, chrysotile to nemalite-brucite. The serpentines must be regarded as a mixt. of the two end members, talc and brucite. This conception coincides with the results obtained from the x-ray investigations of Schiebold, who gives the following equation: $[Si_8O_{20}]\text{-}Mg_6(OH)_4$ (talc) + $6[Mg(OH)_2]$(brucite) ⇄ $[Si_8O_{20}]\text{-}(OH)_{10}Mg_{12} = 2\{Mg_6(OH)_8[Si_4O_{10}]\}$ (serpentine), as well as with the results obtained from dissolving serpentine in NH_4Cl with a max. yield of Mg from serpentine of 66% which amt. corresponds to the amt. of Mg which is combined with the hydroxides in the mineral. W. R. H.

Hibschite in Georgia. D. S. Belyankin and V. P. Petrov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 349-52 (1939)(in English).—A mineralogical characterization and optical consts. of Caucasian hibschite are followed by an analysis of the mineral. A. H. Krappe

The identity of molengraaffite with lamprophyllite. C. E. Tilley. *Trans. Geol. Soc. S. Africa* **41**, 109-11(1938); *Am. Mineral.* **24**, 728(1939).—A new partial analysis of molengraaffite from Pilansberg gave: CaO 1.9, SrO 14.4 and BaO 1.8. The original analysis, therefore, appears to be in error, SrO and BaO being included in the CaO. This identity is confirmed by a comparison of optical properties. C. H. Hale

Relation of chamosite and daphnite to the chlorite group. A. F. Hallimond, C. O. Harvey and F. A. Bannister. *Mineralog. Mag.* **25**, 441-65(1939).—Existing

information on chamosite, daphnite, bavalite, leptochlorite, orthochlorite, thuringite, amesite, corundophillite, prochlorite, clinochlore, pennine and cronstedtite is discussed, and the 79 most reliable analyses are plotted with the ratios $2OOR_2O_3/SiO_2$ and $2OORO/SiO_2$ as coördinates; analyses of the first 5 are also plotted with the ratios FeO/(FeO + MgO) and $2OORO/SiO_2$ as coördinates, bringing out certain relationships. X-ray diagrams of chamosite, daphnite and some other chlorites are given and new analyses of chamosite from Cornwall (Tolgus mine) and of daphnite from Lincolnshire (Frodingham). These show chamosite to be approx. $2SiO_2.Al_2O_3.3FeO,nH_2O$ with a special structure of the chlorite type, while that of daphnite is of normal chlorite type resembling that of clinochlore. 26 references. C. A. Silberrad

Isodimorphism between metavariscite, variscite, phosphosiderite and strengite. H. Strunz and K. v. Sztrókay. *Zentr. Mineral., Geol.* **1939A**, 272–8.—The results of McConnell (*C. A.* **33**, 9208[2]) are confirmed. Phosphosiderite, $FePO_4.2H_2O$, is monoclinic and probably isomorphous with metavariscite, $AlPO_4.2H_2O$. Variscite, $AlPO_4.2H_2O$, is orthorhombic, isomorphous with strengite, $FePO_4.2H_2O$, and scorodite, $FeAsO_4.2H_2O$. The existence of a monoclinic "clinoscorodite" is probable. Michael Fleischer

Datolite from the volcanic group of the Karadag in the Crimea. M. N. Shkabara and E. A. Shturm. *Compt. rend. acad. sci. U. R. S. S.* **24**, 166–70(1939)(in English). A description of (1) violet, (2) watery and (3) barrel-like datolite crystals including crystallographic features is followed by a chem. analysis of each type. 7 references. A. H. Krappe

Datolite from the Soganlug talus in the neighborhood of the town of Tbilissi. G. V. Gvakhariya. *Compt. rend. acad. sci. U. R. S. S.* **24**, 162–5(1939)(in English). An interpretation of the interrelation of the crystal forms of datolite from the Soganlug talus (Caucasus) includes a brief geol. survey of the region, a description of 4 types of datolite crystals, with Goldschmidt and Dana (cf. D. and Ford, *Text-Book of Mineralogy*, *C. A.* **16**, 2100; G., *C. A.* **18**, 1233) indexes (table), an enumeration of the phys. properties and a chem. analysis. A. H. Krappe

Analysis of the paragenesis observed in the Inder deposits of borates. M. N. Godlevskiĭ. *Mém. soc. russe minéral.* **67**, No. 1, 18–29(1938); *Khim. Referat. Zhur.* **2**, No. 4, 44(1939); cf. *C. A.* **33**, 2850[2].—The following borates are found in the Inder region: ulexite, inyoite, colemanite, pandermite, inderite, β-ascharite, hydroboracite and kaliborite. The first 6 are found in the gypsum zone and the rest in the transition zone and in the salt mass. Kaliborite is found only in the salt mass. The paragenesis can be conditionally divided into (1) the "equil." (no replacement of one mineral with another is observed) and (2) the "non-equil." (a definite replacement is observed). The ulexite + β-ascharite, the inyoite + β-ascharite, etc., belong to "equil." type, while the hydroboracite (inyoite + β-ascharite), colemanite + pandermite and a no. of others to the "non-equil." Being unstable at atm. pressures and at the surface temp., hydroboracite undergoes a no. of transformations from the intruding surface water:

hydroboracite → ulexite → inyoite; hydroboracite → β-ascharite ↙ (colemanite) → pander-

mite + carbonates. The colloidal character of most borates was proved. In spite of this the phase rule can be applied to the investigation of the systems of these deposits. By applying the conception of the active and the inert components during metasomatosis (formulated by Korzhinskiĭ), G. was able to study in more detail the systems $(CaO–B_2O_3)$, $(MgO–CaO\ B_2O_3)$, to det. the fields of stability of the single minerals and to det. a no. of conditions of the formation of the Inder borate deposits. W. R. H.

Conversion of astrakhanite. I. G. Druzhinin. *Compt. rend. acad. sci. U. R. S. S.* **23**, 921–4(1939)(in English).—Expts. were made to det. the properties of $Na_2SO_4.MgSO_4.4H_2O$ and the conditions required for the conversion of the mineral into Na_2SO_4 used in the glass and chem. industries. The conversion temps. are given in a table and the heat curves added. On being heated, astrakhanite undergoes 3 conversions: (1) at 105° 2 mols. of H_2O is lost and astrakhanite passes over into loweite $(Na_2SO_4.MgSO_4.2H_2O)$; (2) at 215° anhyd. astrakhanite is formed; (3) at 625° a polymorphous conversion of $Na_2SO_4MgSO_4$ takes place. For anhyd. astrakhanite the refractive indexes are, *ng* 1.650; *np* 1.450. 7 references. A. H. Krappe

The mineralogic composition of acid blast-furnace slags. Dieter Hoenes. *Zentr. Mineral., Geol.* **1939A**, 257–71.—Five slags contained anorthite 41–63, clinopyroxene 5–22 and melilite plus leucite (usually as intergrowths) 23–54. An unidentified mineral, possibly pseudowollastonite, was present in several slags, in considerable amt. in one. The mineralogic compn. and order of crystn. are compared to those of basic hearth slags, coal slags, etc. (cf. Koch, *C. A.* **27**, 4756; **28**, 6400[2]). Two analyses of acid blast-furnace slags are given. Michael Fleischer

The reciprocal action of feldspar, "pyroxene" and sulfide melts. D. P. Grigor'ev. *Mém. soc. russe minéral.* **67**, No. 1, 7–17(1938); *Chem. Zentr.* **1939, II**, 1654.—Mixts. of 58% diopside and 42% anorthite, or 62% diopside and 38% plagioclase were melted with FeS to 1300°. The melts sepd. into a lower sulfide layer where 8–10% silicate is dissolved, and an upper silicate layer in which very little sulfide is dissolved. M. V. Condoide

Dolomitization and anhydritization of limestones of the Ishimbaev petroleum-bearing region. E. P. Aleksandrova. *Trudy Neft. Geol.-Razved. Inst.*, Ser. A, No. **101**, *Materialy k Poznaniyu Ishimbaevskogo Mestorozhdeniya Nefti* 13–26(1938); *Khim. Referat. Zhur.* **2**, No. 4, 40 (1939).—The dolomitized rocks are distributed very unevenly in the midst of the reef limestones. The intensity of dolomitization is very different. Dolomite is formed by a secondary course replacing limestone. The sepn. of anhydrite among the reef limestones is also of a secondary nature. Dolomite and anhydrite replace the skeletons of organisms and the cement between them. The dolomitized rocks are porous; this can be explained by a decrease of the vol. during the change from limestones to dolomites and by the partial soln. of anhydrite and calcite. Intensive petroleum activity is observed in dolomitized varieties of limestones. The formation of dolomite and anhydrite is explained by the reaction of a $MgSO_4$ soln. on limestone, which takes place in a lagoon-type reservoir with an increased concn. of salts. W. R. Henn

Study of the kaolinized Tirschenreuth granite, which has been referred to in ceramic work as "pegmatite." J. H. Hellmers and P. Pfeffer. *Z. prakt. Geol.* **47**, 192–6 (1939).—Microscopic study and analyses of samples from 4 depths show that the kaolinization is a surface phenomenon and decreases rapidly with depth. M. F.

Contact metamorphism of phosphorites. P. L. Bezrukov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 282–4 (1939)(in English).—Intense metamorphism of the lower Paleozoic phosphate beds in contact with Caledonian granite, observed at Kara-Tau, So. Kazakhstan, led to a close study of the phenomenon, involving a detailed geol. description of the prevailing conditions and of the metamorphism of the phosphorites into apatite beds. There are reasons to believe that thermal metamorphism was accompanied by an admixt. of volatile components carried in by the intrusion. The metamorphism involves complete destruction of the phosphorite crystals. The P_2O_5 content of the apatite layer amounts to 21.3% and in some cases to as much as 32%. 2 references. A. H. Krappe

Gold deposits in the Bashkir republic. I. E. Leshchuk. *Zolotaya Prom.* **11**, No. 4–5, 18–22(1939).—Descriptive. B. Z. Kamich

Gold and silver in the ores of Kounrad. M. A. Shibakov. *Mineral. Syr'e* **1938**, No. 2, 59–62; *Khim. Referat. Zhur.* **2**, No. 4, 43(1939).—A universal and fairly const. distribution of Au and Ag is noted in the ores of Kounrad. The Ag and the Au minerals are absent in the primary ores. Au is found in the form of 0.005–0.05-mm. grains only in the zone of the oxidized ores, mostly assocd. with limonite. Pyrite and chalcopyrite are considered to be the primary Au-contg. minerals. Ag, apparently, is one of the components of weathered ores of the freibergite type (Cu-Ag-Sb ore which probably contains

As). The weathered ores are evenly distributed in the form of very fine grains. The content of Ag is slightly increased in the surface processes of the oxidized zone of the deposits. The extn. of these metals together with Cu is discussed. W. R. Henn

The geology and development of Mill Close Mine, Derbyshire. J. G. Traill. *Econ. Geol.* **34**, 851–89 (1939).—Galena and sphalerite, with calcite, pyrite, fluorite and barite, occur in metasomatic replacement veins in limestone. The galena carries only 1 to 1½ oz. Ag per ton. The sphalerite is exceptionally pure, averaging 65% Zn and 1% Cd. Structural factors such as jointing and faulting, the presence of favorable limestone beds, and especially the presence of impermeable lava flows under which the ore is concd., largely controlled the paths followed by the ore-bringing solns. The deposit is very similar to the manto deposits of Mexico (cf. Prescott, *C. A.* **20**, 3669). From 1929 to 1938, over 222,000 tons of Pb concentrates and 21,500 tons of Zn concentrates were produced, but the production of Zn now exceeds that of Pb. Seven analyses of limestones are included. M. F.

Genesis of the Novo-Troytsky iron ore deposit of the Khalilov type. G. I. Teodorovich. *Compt. rend. acad. sci. U. R. S. S.* **24**, 270–3(1939)(in English).—A geol. description of the ore bed is given with views on the genesis of the various constituents including secondary changes. The Fe ores originated in the littoral region of a system of lakes with a prevailing pH that did not permit pptn. of $CaCO_3$. Part of the ferric Fe was reduced to ferrous by org. substances in the silt. A warm climate must have prevailed, and the process is likely to have taken place in the Jurassic period. 4 references. A. H. Krappe

The tin-containing pegmatites. M. F. Strelkin. *Bull. acad. sci. U. R. S. S., Sér. géol.* **1938**, No. 3, 465–86; *Khim. Referat. Zhur.* **2**, No. 4, 41(1939).—A theory of the formation of cassiterite as a result of the hydrolysis of the alkali stannate, $Na_2SnO_3 + H_2O \rightarrow SnO_2 + 2NaOH$, is based on the lowered content of F in minerals contg. F or OH, on the paragenic interrelationship of the minerals of the deposits, and on the strongly developed process of albitization of K feldspar by the NaOH solns. which are formed during the hydrolysis of stannates. The Sn-contg. pegmatites of the Turkestan ridge are connected with the granite intrusion which breaks through the Middle Paleozoic sedimentary formations. The pegmatic veins are represented by (1) schorlo-biotites, (2) schorlo-muscovites, and (3) albites which are Sn-bearing and which are subdivided into cleavelandite-spodumenes and into greisenized veins. W. R. Henn

Geochemistry of titanium, vanadium and chromium in the titano-magnetites of the Ural mountains. P. G. Panteleev. *Bull. acad. sci. U. R. S. S., Sér. géol.* **1938**, No. 3, 449–62; *Khim. Referat. Zhur.* **2**, No. 4, 42(1939).—P. divides all the titano-magnetite deposits into the Kusin-Kapan type (14–15% of TiO_2) and the Pervoural'sko-Kochkanar type (3–6% of TiO_2). The ratio Ti Fe for the first type is 0.14–0.18 and 0.03–0.06 for the second type. These ratios as well as a no. of genetic and geol. differences are explained by the different geol. ages of the formations of these 2 types: the Pre-Cambrian for the first and the Devonian for the second. The contents of Cr and Fe in the ores increase in the direction from west to east and the ratio of Ti to Fe decreases in the same direction. The amt. of V is increased in the central deposits, but the ratio V:Fe remains more or less const. W. R. Henn

Technical agate in U. S. S. R. and problems for the investigation of its deposits. S. S. Vanyushin. *Mém. soc. russe minéral.* **67**, No. 1, 141–53(1938); *Khim. Referat. Zhur.* **2**, No. 4, 37–8(1939).—The tech. agate deposits in Georgia, Armenia and Azerbaïdzhan are described. Of the agates of the Caucasus regions, those occurring as nuggets in porphyrites and andesites are of the highest quality. Agates found in veins in the same deposits are of poorer quality. Tube-shaped agates (in the Pomach and Akhaltsykh deposits) are usually 0.5–50 cm. in diam. Some tubes are completely filled with agate while others are hollow with a smooth inner surface or a surface covered with quartz crystals. Agates in the form of specks are very numerous. Agate in sedimentary deposits gives no suitable tech. raw material. The microstructure of the tech. agates is described very briefly. W. R. Henn

A new bauxite-bearing region in Siberia. L. A. Rogozin. *Razvedka Nedr* **1938**, No. 10, 18–23; *Khim. Referat. Zhur.* **2**, No. 4, 40(1939).—Sharp-angled 30 × 20 × 15-cm. bauxite fragments were found 1.5 km. above the Ust-Sertinskaya village on the right bank of the Kiya River in the northern part of Kuznetskiĭ Alatan. The bauxites have an oölite texture with a brown-colored main mass which consists of limonite and goethite. The chem. analysis of the bauxite gave Al_2O_3 27.70, Fe_2O_3 23.74 and SiO_2 28.65%. In their petrographic properties and chem. compn. the Ust-Sertinskaya bauxites are like the Salair and the Eniseĭ bauxites. Their age is conditionally taken as Jurassic. The bauxites were formed in ancient river valleys by the deposition of materials rich in clay. W. R. Henn

Ribbon clays in the vicinity of Leningrad. N. A. Uspenskiĭ. *Mém. soc. russe minéral.* **67**, No. 1, 87–101 (1938); *Khim. Referat. Zhur.* **2**, No. 4, 37(1939).—Microscopic investigation of polished specimens of clays from along the Izhora River between Kolpino and Ust-Izhora showed the presence of brown mica, thin-scaled sericite-like mineral, carbonate, glauconite, quartz, feldspar, muscovite, biotite, chlorite, amphibole, garnet, epidote and tourmaline. U. emphasizes the little dependability of the detns. of the mineral compn. of clays which are based on the data of chem. analyses only. The investigation of the mineralogic compn. by means of polished specimens is more dependable than the method with immersion liquids because of the destruction of the soft minerals. W. R. Henn

Copals and their utilization. V. A. Oskolkov. *Razvedka Nedr* **1938**, No. 8–9, 6–11; *Khim. Referat. Zhur.* **2**, No. 4, 46(1939).—The known copal deposits in U. S. S. R. are represented by 2 types: (1) the true copal deposits in which they are found as monominerals in the sand-clay formations (Zakavkaz'e, Kazakhstan and probably Turkmen), (2) inclusions among the younger coal deposits in the Far Eastern region. The Verkhne-Agdzhekend deposit contains 20–300 mg. (with an av. of 200 mg.) of copal/cu. m. of the formation. The copal-contg. soft-coal deposits of the Far Eastern region are the Artem, Shkotov and Khungarin shafts. The Artem shaft contains an av. of 0.0025% of copal which is distributed irregularly among the coal in the form of fine and coarse milky-white and orange grains. The copal deposits sometimes contain interlayers of copals. Other copal deposits are described and the results given of the technological studies for the enrichment of the copal ore and for the utilization of the deposits. W. R. Henn

C. Wiman's "Psilophyton-like fossil from Lapland." Oskar Kulling. *Geol. Foren. Förh.* **61**, 412–15(1939).—Analyses for CaO and MgO ignition loss and for part insol. in dil. HCl, of (1) the *Psilophyton*-contg. rock, (2) dolomite from Kalv Mountain and (3) gray dolomite quartz veins from Kalv Mountain are given in an attempt to det. the origin of the fossil. Wilhelm Segerblom

Cone-in-cone [structures] from Lufubu [River], Manema, Belgian Congo. Marcel E. Denaeyer. *Ann. soc. géol. Belg., Bull.* **62**, 493–511(1938–39).—Macroscopic and microscopic descriptions of 2 specimens of calcareous cone-in-cone structures. The principal constituent is calcite with 2.34% SrO. The origin of these growths and a possible relation with neighboring, nonstrontianiferous, thermal, saline springs previously described (Cornet, *Ann. soc. géol. Belg.* **38**, 16(1910–11); Mathieu, *Ibid.* **40**, 103–25 (1912–13)) are discussed. D. W. Pearce

Siberian petroleum—crystalline shales of Main Caucasus Divide and their origin (Senyukov, Shmelev) **22**.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Metal-working industries in Canada. W. H. Losee and H. McLeod. *Can. Metals Met. Inds.* **2**, 286, 288, 311–12, 314, 316(1939).—A summary of production value and tonnage for 1938 and the previous decade. W. H. B.

The flotation of the blue schist of Recsk. József Finkey. *Math. naturw. Anz. ung. Akad. Wiss.* **58**, 608–17(1939).— This blue schist consists probably of decayed, kaolinic andesite tuff, and contains an av. of 15% pyrite and 5–15 g. Au per ton. Use of a sulfuric acid-contg. bath and the addn. of protective colloids did not give successful flotation of this ore. The schist contains a large amt. of water-... ulfates, especially Al sulfate. The Al ions prevent the coagulation of the ore foam. This disturbing effect can be removed by the use of a soda-contg. flotation bath. Practical expts. showed that the following reagents are required for each metric ton of flotation bath: 20 kg. cryst. sodium carbonate, 160 g. K ethylxanthate, 100 g. pine-needle oil and 300 g. water glass (to prevent coagulation of the kaolin). The pyrite yield was in this case 78% and the product contained 40% S. S. S. de Finály

Kinetics and adhesion of mineral particles to air bubbles in flotation suspensions. M. A. Elgeles. *Compt. rend. ad. sci. U. R. S. S.* **24**, 340–4(1939)(in English).—From a study of the adhesion to an air bubble of mineral particles of the type commonly used in flotation (fluorite, barite, calcite) by means of an elec. contact app. (described), conclusions are drawn as to role of the accumulator, which increases the attraction between the particles and the bubble and provides the required adhesion kinetics. 6 references. A. H. Krappe

Flotation problems in treatment of gold ores. P. Blewett. *Mining J.* (Phoenix, Ariz.) **23**, No. 9, 6(1939).—A discussion of flotation alone and of a combination of flotation and cyanidation or amalgamation; the flow sheet depends on the characteristics and chem. analysis of the particular ore to be treated. Leopold Scheflan

Synthetic flotation oils from turpentines. D. I. El'kin. *Lesokhim. Prom.* **6**, No. 2, 32–3(1938); *Khim. Referat. Zhur.* **2**, No. 3, 125–6(1939).—Yields of flotation oils were 43% from natural turpentines, 47.6% from the steam resin-soap industry and 37.2% from the resin-extn. industry. The flotation oils obtained are 45–55% cheaper than those obtained from dry-distn. turpentines. W. R. Henn

Mineral production of the South. George C. Branner. *Mins Record* **108**, No. 11, 18–27(1939).—A detailed illustrated survey of the metal mining industry in the southern states of the U. S. Leopold Scheflan

Assaying rich telluride-gold ores. H. F. Silva. *Chem. Eng. Mining Rev.* **32**, 59–66(1939).—The most suitable flux for assaying telluride Au ores contains 8 parts PbO, 8 parts soda ash and 1 part NaCl. Cupellation losses are discussed and means outlined of minimizing these losses; they include low temp. and a 10–1 Ag:Au ratio in the button weighing not less than 30.0 g. Cement cupels are shown to be satisfactory if precautions are taken. The standard fire assaying method is described. W. H. B.

Present milling practice at the Porcupine gold mines. Henry Hanson. *Can. Mining J.* **60**, 804–9(1939).—A description together with a complete flowsheet for the Hollinger mill. W. H. Boynton

Sintering iron ores in suspension. A. M. Parfenov. *Sovet. Met.* **1938**, No. 2, 11–20; *Khim. Referat. Zhur.* **2**, No. 4, 92(1939).—The rich Magnitnaya Gora ore contg. about 63% of Fe was used for the expts. in 2 fractions: 0–1 mm. and 0–3 mm., and the Kerch concentrate contg. about 44% of Fe in 3 fractions: 0–1 mm., 0–3 mm. and 0–5 mm. The ore was blown into the upper part of a cylindrical 0.6-cu. m. shaft by means of air heated in a recuperator. A special cast-iron directing cone was constructed along the whole cross-section of the shaft in the upper part of the furnace for an even distribution of the falling ore. Two petroleum sprays were attached tangentially to the walls in the lower part of the furnace. The combustion products of petroleum were led through the upper part of the furnace into the recuperator and then released into the atm. The optimum temp. was 900–1100°. The agglomerate formed in part a finely porous mass and in part a fused mass or an oxidized agglomerate with large pores which crumbled easily. The orienting expts. showed a productivity of the furnace of about 600 kg./hr./cu. m. W. R. Henn

Agglomerates obtained from Magnitogorsk ores and blast-furnace dust. E. T. Kaminskaya-Dul'skaya. *Sovet. Met.* **1938**, No. 2, 3–10; *Khim. Referat. Zhur.* **2**, No. 4, 92–3(1939).—Fine ore 25, limonite 20 and blast-furnace dust 25% roasted for 24 hrs. yielded a fine-grained agglomerate contg. 7.8% of FeO. The yield of fines was 49.5%. The roasting was performed without any addn. of fuel, at the expense of the 9% combustible substances in the blast-furnace dust. Roasting 35% of fine ore, 40% of blast-furnace dust and 25% of the returned agglomerate with addn. of 5.6% of fuel gave a better product; fines 29.5%. In the agglomeration process the martite is first reduced to magnetite, which is oxidized to hematite. The nonore minerals are mostly unfused. Two samples with 55 and 45% of fine ore, 20 and 30% of blast-furnace dust and 25% of returned ore when roasted with 7.8 and 6.85% of fuel yielded 16.2 and 19.5%, resp., of fine ore and a fused easily crumbling agglomerate. The process is mostly one of reduction (martite to magnetite). The contents of FeO were 30.5 and 40%. Roasting of fine ore yielded an agglomerate of cryst. structure with fused ore minerals (magnetite) and with nonore minerals (glass, fayalite), and 23% of fines. Roasting 70% of blast-furnace dust with 5% of fine ore gave an agglomerate with a weakly developed globular structure and lower strength, and a 17.8% yield of fines. The content of FeO was 22.5%. At 110–100° the drying and the loss of water of hydration take place; at 500–600° the kaolin nucleus is formed (a considerable absorption of heat by the clay components); at 1100–1300° the feldspars and garnet are fused; at 1400° magnetite is fused. A min. amt. of garnet is necessary to obtain a fused agglomerate. The production of cryst. agglomerate is not profitable, owing to the large amt. of fuel necessary. Photographs of the microstructures and the compns. of the mixts. and of the agglomerate are given. W. R. Henn

Secondary metals. C. L. Smith. *Mines Mag.* (Colo. School of Mines) **29**, 510–12(1939).—A description of the industry dealing with the recovery of secondary and scrap metal. Leopold Scheflan

Recovery of slag with high content of vanadium in the basic Bessemer and its use in the electric-arc furnace. A. Harr. *Stahl u. Eisen* **59**, 1145–54, 1174–81(1939).— The need of Germany for V has been increasing and more thoroughgoing attempts have been made to recover V from basic Bessemer slag. Basic Bessemer pig iron in Germany contains an average of 0.12% V and 80% of this goes into the converter slag. In a series of tests converter dust which settles on the roofs of the Bessemer mill and contains as much as 1% V was smelted in a blast furnace. This pig iron was then blown in a converter and the resulting slag contg. over 10% V was charged into elec. furnaces for making alloy steel contg. up to 0.4% V. In this way about 60% of all the original V was recovered. Recovery of V in the basic Bessemer converter slag is aided by the admixt. of roll scale. S. Epstein

Method of heating and operation of ore-preparation equipment. K. Guthmann. *Stahl u. Eisen* **59**, 1125–33 (1939).—Practical. A discussion of modern sintering technique. 24 references. S. Epstein

Firing of the Martin furnace with cold coke gas. I. G. Kazantsev. *Teoriyai Prakt. Met.* **1938**, No. 9, 27–32; *Khim. Referat. Zhur.* **2**, No. 4, 95(1939).—Cold coke gas purified from S is the most economical fuel for the Martin furnace. A part of the excess heat (0.3×10^6 cal./ton of metallurgical coke) can be used for other purposes. The

use of cold coke gas lowers considerably the expense of the construction of different parts of the equipment and simplifies the automatic regulation of the furnace. It also intensifies the process and increases the stability of the lower part of the furnace. The high content of H_2S (20 g./cu. m.), which is a hindrance to a wider use of the cold coke gas, can be removed. The technology of the purification of the gas has been developed in detail for gases used in the synthesis of NH_3. W. R. Henn

Metallurgical studies of oxygenated blast in basic Bessemer practice. W. Eilender and W. Roeser. *Stahl u. Eisen* **59**, 1057-66(1939).—O_2-enriched air may give the following advantages: shorter time of blow, lower Mn losses, means of using more scrap, somewhat lower and at least no higher oxidation of the bath, lower S and N_2 content of the bath. About the best O_2 enrichment was to 28% O_2 in the blow. The fact that oxidation of the bath was not increased was considered to result from the more rapid heating of the charge and hence the faster melting of the lime, and a generally more favorable temp. cycle. The faster melting of the lime likewise resulted in better desulfurization; more of the S was also given off as SO_2 because of the higher O_2 content of the blow. The N_2 content of the bath was lowered from about 0.016 to about 0.013% N_2. The increase in output with 28% O_2 in the blow amounted to about 16%. Relatively low-P pig iron with 1.19 to 1.35% P could be used when the blow was enriched to 31% O_2. It is stated that with present O_2 costs with the Linde process, the use of O_2-enriched blow for the basic Bessemer process in Germany is economical. 22 references. S. Epstein

Blowing coke gases into the blast furnace. M. A. Shapovalov. *Teoriya i Prakt. Met.* **1938**, No. 11, 24-6; *Khim. Referat. Zhur.* **2**, No. 4, 94(1939).—A blast-furnace gas suitable for the *synthesis of* NH_3 (with a simultaneous production of cast iron in the blast furnace) can be obtained by blowing coke gas into the furnace together with O. This permits obtaining a ratio $(CO + H)/N = 3.2$ in the blast-furnace gas with a content of O in the blown air of less than 60%. The use of hot blowing replaces in the heat balance of the furnace a part of the expensive coke heat. More than 2 cu. m. of coke gas can be blown in for each kg. of C. The O content in the blast should be 43-5%. By preliminary sepn. of H from the coke gas (by cooling) and adding it to the blast-furnace gas, the amt. of the blast gas will be reduced to approx. one-half. A no. of curves and tech. data are given. W. R. Henn

The present status of the Krupp-Renn reduction process. F. Johannsen. *Stahl u. Eisen* **59**, 1041-6(1939).—See *C. A.* **33**, 9220⁴. S. Epstein

Foundry facings. J. Ridderhof. *Can. Metals Met. Inds.* **2**, 299-303(1939)—A review of the types of facings used, from an analytical as well as a practical viewpoint. The properties and application of sea coal, core washes, plumbago and parting are discussed. Characteristics desired in sea coal are volatile matter 33-36%, S not above 1%, ash 6-7% and moisture not over 1.5%. Core wash may be applied to dry sand or baked cores, by dipping or spraying. The Baumé of a core wash soln. must be controlled. Water base core wash solns. are alone considered here. Ten points to be considered in making a core wash are listed. The types of graphite employed in facing and their specific properties are noted. Parting is the material shaken through a cloth bag on to sand joints or on to loose patterns or pattern plates to ensure a clean lift of the pattern or a clean sepn. of the core from the drag. Materials used are listed. W. H. Bovnton

Beryllium and its alloys. Recent developments in fields of application. Louis L. Stott. *Metal Ind.* (London) **55**, 470-2(1939). E. H.

Corrosion of light metals and of their alloys by metallic mercury. V. S Zotin. *Korroziya* **4**, No. 2, 142-7(1938); *Khim. Referat. Zhur.* **2**, No. 2, 137(1939).—The corroding action of metallic Hg was investigated on Al with small admixt. of impurities, on duralumin, on Mg (99.98%), on Mg (tech.), on the AZ "elektron" and on the Z3 "elektron." The rolled metals (except Mg, which was cast) were tested. Drops of Hg were added to the metals and the corrosion processes were investigated. The largest amt. of corrosion was observed on the metal alloys (especially on the tech. Mg and on the "elektrons"), while pure Mg was almost immune to corrosion. The velocity and the degree of corrosion increased with the increase of the humidity of the atm. and they did not depend on its compn. (the expts. were also performed in H, O, A and CO_2). The protective films on the metals preserved the metals, but did not ensure abs. protection from Hg corrosion. W. R. Henn

Ore briquets. Otto Seidl (to Hungaria Kunstdünger, Schwefelsaure und chemische Industrie). U. S. 2,177,228, Oct. 24. To prepare briquets suitable for smelting operations, ore material such as copper pyrites is mixed with about 2% or less of sugar material such as sugar and briquets formed of the mixt. are hardened by heating at about 200-300°.

Treating manganese ores. Andrew T. Sweet and John D. MacCarthy (to General Manganese Corp.). U. S. 2,176,774, Oct. 17. A method of extg. Mn compds. from complex carbonate ores contg. Mn and Fe comprises calcining the ore to eliminate the carbonates, sulfatizing the calcined product, roasting the sulfatized product in the presence of air at a temp. of approx. 650° until the iron is oxidized into a condition relatively insol. in water, leaching with water, sepg. sol. Mn sulfate from the insol. residue, pptg. a Mn compd. from the soln. and heating the ppt. to a temp. forming a Mn oxide sinter. U. S. 2,176,775 relates to a process of recovering Mn compds. from ores contg. appreciable amts. of Mn oxides which involves roasting the ores with an NH_4 salt such as the sulfate, ca-

pable of forming a sol. Mn compd. with evolution of NH_3 gases, sepg. the sol. Mn salt from the insol. residue, pptg. insol. Mn hydroxide with NH_4OH derived from the NH_3 gases, thereby reforming the NH_4 salt in soln., and sepg. and evapg. the soln. to recover the NH_4 salt for further use in the cycle. U. S. 2,176,776 relates to a generally similar process with use of NH_4Cl instead of the sulfate.

Working ores of vanadium and uranium. Charles J. Stamberg (to North Shore Coke & Chemical Co.). U. S. 2,176,610, Oct. 17. A process for the recovery of V and U values from ores contg. them in assocn. with compds. of Fe and Al comprises sulfatizing such an ore to solubilize V and U values, leaching solubilized values from the sulfatized ore, subjecting the resultant acid leach soln. to heat and the action of a suitable oxidizing agent to hydrolyze and ppt. V values therefrom, while adjusting and maintaining the degree of acidity of the acid leach soln. within desired limits with the aid, as a neutralizing agent, of a basic Fe-contg. ppt. obtained at a later stage of the process, sepg. the resultant V ppt., subjecting the residual soln. to a purifying treatment which includes removal of Fe and Al as a basic Fe-contg. ppt., utilizing such ppt. in cycle as a neutralizing agent in adjusting and maintaining the degree of acidity of a further quantity of the acid leach soln and recovering U values from the residual purified soln.

Treating ores containing vanadium, uranium and radium. Harry McCormack (to North Shore Coke & Chemical Co.). U. S. 2,176,609, Oct. 17. A process of treating siliceous ores contg. V, U and Ra values involves mixing with the ore in comminuted condition a quantity of $(NH_4)_2SO_4$ sufficient for reaction with the sulfate-forming components thereof, subjecting the mixt. in dry condition to regulated moderate heating, with access of air, at reacting temp. not exceeding about 475° until adequate sulfatization of the V and U values is effected, leaching the resultant product with water to ext. the solubilized values, sepg. the resultant leach soln. together with suspended Ra-slimes from the undissolved residue, sepg. the slimes from the leach soln., and subjecting the clarified soln. to appropriate treatment for recovery therefrom of its contained V and U values.

Ore car adapted for use in roasting furnaces. Zachriah T. Parker. U. S. 2,177,741, Oct. 31. Details are given of a car with slots in its sides for egress of volatilized ore gases, suitable for use in roasting various ores.

Ore-roasting and smelting reverberatory furnace. Hans W. Jaeger (50% to Fred B. Dawley). U. S. 2,177,654, Oct. 31. Various structural, mech. and operative details of a furnace having a roasting chamber directly above a smelting chamber.

Open-hearth furnace. Wm. A. Morton (to Amco, Inc.). U. S. 2,176,270, Oct. 17. Various structural and operative details.

Regenerative metallurgical furnaces such as open-hearth steel furnaces. Lewis B. Lindemuth. U. S. 2,176,674, Oct. 17. A metallurgical furnace is associated with a regenerative chamber, a tunnel under the furnace from the chamber, checkerwork providing smooth-walled vertical passages through the chamber to a height above its base (the base being free from transverse obstructions and the tunnel being of sufficient height and width to permit of cleaning the entire base of the chamber from the tunnel).

Sweating furnace suitable for treating scrap metals. Leo Mejselman and Rawson E. Stark (to American Smelting and Refining Co.). U. S. 2,176,267, Oct. 17. A sweating furnace comprises 2 telescoping drums inclined from the horizontal and with a space between their walls and bands of slots in their walls permitting flow of fused metal from the interior of the drum of smaller diam. into the space and thence out of the furnace.

Cupola furnace suitable for treating pig iron, etc. Laurence A. Grotewohl (to Campbell, Wyant & Cannon Foundry Co.). U. S. 2,176,336, Oct. 17. A furnace is described having an outer metal shell and an inner lining of fire-resisting material, an annular metal member of substantially channel-shaped cross section secured at the inner side of the shell at a zone of the furnace where the heat is severe, a similar annular channel-shaped metal member secured around the outer side of the shell, opposite the first channel member, whereby two continuous annular chambers are made, the shell between the chambers having openings, and means for continuously circulating water through the chambers.

Reducing metal compounds. Norman D. Scott and Joseph F. Walker (to E. I. du Pont de Nemours & Co.). U. S. 2,177,412, Oct. 24. Metal compds. (other than alkali metal compds.) such as a Pb salt or a Hg salt are treated with a soln. of the alkali metal addn. compd. of an org. compd., e. g., a Na-naphthalene addn. compd., to effect production of products such as a Pb-Na or Hg-Na alloy.

Grading sheets of magnetic material such as tin plate according to weight. James J. Bowden. U. S. 2,176,784, Oct. 17. App. is described, and a process of grading according to wt. sheets of material of substantially uniform magnetic susceptibility comprising subjecting such sheets first to a magnetic field capable of lifting the same, and then conveying the sheets thus lifted within the influence of a magnetic field of such strength as to release such of the sheets as are above a predetd. wt.

Grinding or polishing sheet metal such as that of the stainless type. Henry H. Giles and Carl M. Nystrom (to American Sheet and Tin Plate Co.). U. S. 2,177,316, Oct. 24. In the use of a roll or belt coated with abrasive grains, these grains are flushed with palm oil during a grinding or polishing operation so as to remove loosened grains from between those remaining on the roll or belt and to prevent the formation of dust from the loosened grains.

Pickling coils of metal such as strip steel. Agnes J. R. Greer. U. S. 2,176,900, Oct. 24. Various details of app. and operation by which pickling liquid is pumped through convolutions of the metal by alternate compression and expansion of the convolutions on opposite sides of the coil.

Pickling ferrous metals. Robert L. Brandt (to Colgate-Palmolive-Peet Co.). U. S. 2,176,389, Oct. 17. For pickling, use is made of an aq. soln. of an acid consisting of the reaction product of a material obtained from a mineral oil by solvent extn., as with liquid SO_2, and a sulfonating agent, the product being made in soln. in liquid SO_2 (suitably by use of oleum).

Treating strip metal as in tempering, etc. Carl E. Moore. U. S. 2,176,094, Oct. 17. An arrangement of app. is described, and a method of treating strip metal which includes cold-reducing the metal to approx. the desired gage, annealing the cold-reduced strip metal, temper-rolling the annealed metal in a cold-rolling mill whereby the strip metal is characterized by a wavy surface which is produced by longitudinally extending metallic fibers of unequal length, withdrawing the temper-rolled material from the cold-rolling mill by passing between a plurality of power-driven spaced-apart rolls which are constructed and arranged to tension the temper-rolled strip metal sufficiently to stretch the shorter of the longitudinally extending fibers of the metal without elongating it over its entire width, and delivering the strip metal from the power-driven spaced-apart rolls in a substantially untensioned state.

Metal heat-treatments, as in case hardening. Crandall Z. Rosecrans (to Leeds & Northrup Co.). U. S. 2,176,473, Oct. 17. A heat-treatment app. suitable for forming a diffusion alloy case comprises a furnace including a chamber for metal objects, means providing a passage for discharge into the chamber of a treating liquid, unmixed with gas, which by pyrolytic breakdown forms the atm. in which the objects are treated, the feeding means for the liquid comprising a positive displacement pump for exerting upon the liquid a pulsating pressure which increases upon increase of resistance to flow of the liquid through the passage to ensure feed of a const. metered amt. of the liquid per unit of time irrespective of greater or lesser obstruction of the passage as by the breakdown products of the liquid, which may be atomized fusel oil or carbitol, etc.

Photoelectric control of metal heat-treatments such as those effected by an oxyacetylene flame. James H. Bucknam (to Linde Air Products Co.). U. S. 2,177,276, Oct. 24. An arrangement of app. is described, and a process of heating, welding, desurfacing or cutting a ferrous metal article along a predetd. line which comprises locally heating the metal article at the starting point of the line; initiating relative movement between the metal article and the source of heat photoelectrically in response to a predetd. intensity of radiant energy emitted by the heated area at the starting point, progressively to heat successive portions of the article along the line; and stopping the relative movement at any point along the line photoelectrically in response to a decrease to below such predetd. intensity of emitted radiant energy.

Heat-treatment of articles as in bright annealing tubes, etc. Thomas G. Tanner. U. S. 2,177,031, Oct. 24. An arrangement of app. is described, and a method of heat-treatment in the heat-treatment chamber of a continuous furnace of articles contaminated with oil or grease, comprising preheating the articles in an inlet chamber, maintaining the temp. in the inlet chamber at a substantially const. temp. between the volatilization and cracking temps. of the oil or grease, entraining the vapors produced by the volatilization of the oil or grease in a stream of a protective gas outflowing from the treatment chamber, and cooling the protective gas between the treatment chamber and the inlet chamber to reduce its temp. below the cracking temp. of the vapors.

Apparatus for annealing rapidly moving electrically heated wire. John Cook (to Cornish Wire Co.). U. S. 2,176,582-3, Oct. 17. App. used may include means for passing an elec. current through a portion of the wire to heat it to the annealing temp., a water bath for quenching the heated wire after annealing, an open-ended electrically and heat-insulated tube closely surrounding the highly heated portion of the wire, the lower end of the tube extending below the surface of the water bath a sufficient distance as to cause a local heating of the water confined in the tube to the b. p. to effect flash production of steam to envelop the heated wire with a nonoxidizing atm. before it passes into the water bath and thus prevent discoloration of the wire.

Apparatus for producing desulfurized pig iron. Russell P. Heuer. U. S. 2,177,716, Oct. 31. App. used comprises a desulfurizing vessel having a C lining in the portion which is to hold a charge, a basic desulfurizing slag within the lining of the desulfurizing vessel, means for sealing the interior of the desulfurizing vessel from the outside atm. and means for producing and maintaining a pressure substantially below atm. pressure in the interior of the desulfurizing vessel.

Alloy steels containing chromium. Marvin J. Udy. U. S. 2,176,686, Oct. 17. A compn. for use in making alloy steels contg. Cr comprises an intimate mixt. of Fe oxide, ferrochrome silicon low in C and contg. sufficient Si to reduce all the Fe oxide to metal and lime sufficient to flux the silica formed in the reduction (the compn. being capable of conversion by internal exothermic reactions into a ferrous Cr alloy and a basic Ca silicate slag). U. S. 2,176,687 relates to a material made from chromite ore comprising oxidized ferro-Cr substantially free of C in finely divided admixt. with low-C ferrochrome-Si of a Si content sufficient to reduce the metal oxides of the oxidized ferro-Cr. U. S. 2,176,688 relates to a method of producing a compositie reagent suitable for use in the production of Cr alloys which comprises oxidizing C-bearing ferro-Cr and forming an oxidized product low in C and contg. Fe and Cr in oxidized forms, and mixing the oxidized product in the solid state with a solid noncarbonaceous reducing agent such as ferro-Si capable of reducing the oxidized forms of Fe and Cr to metallic form. U. S. 2,176,689 relates to a process of making ferrochrome silicon of controlled Si and C contents by reduction of chrome Fe ore with C which involves smelting the ore in a submerged arc elec. furnace in the presence of lime and with SiO_2 present in excess of the amt. required to form with the lime present in the charge a slag having a ratio of CaO to SiO_2 of about 1.7-2.2.1, resp., reducing the Fe and Cr of the ore and the Si of the excess SiO_2, and withdrawing from the furnace molten ferrochrome silicon and molten slag contg. CaO and SiO_2 in the stated ratio.

Alloy steel for internal-combustion engine valves, etc. Harry L. Frevert and Francis B. Foley (to Midvale Co.). U. S. 2,177,454, Oct. 24. An alloy of good strength at high temps. and resistant to scaling contains Fe together with C 0.1-1.0, Cr 10-20, Mn and Ni 5-13 (the Mn being 3-10.25 and the Ni 1.75-3.5%), with the percentage of Mn substantially exceeding the percentage of Ni) and Si and Al 2.5-4.5% (the Si being over 1.25%). Cf. *C. A.* **33**, 2875[9].

Hard metal alloy products. Johan Romp (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,176,802, Oct. 17. See Brit. 499,097 (*C. A.* **33**, 4955[1]).

Apparatus for galvanizing metal sheets. Daniel O. Fisher, Kristian Kronborg and Ernest G. Schlup (to American Rolling Mill Co.). U. S. 2,176,761, Oct. 17. Various structural, mech. and operative details of an app. with a cooling wheel and conveyor.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Analysis of hydrocarbons. II. Diene number of hydrocarbons. H. Grosse-Oetringhaus. *Petroleum Z.* **35**, 567-73(1939); cf. *C. A.* **33**, 9609[8].—The diene-maleic anhydride reaction was studied to det. the effect of temp., reaction time, concn. of reagent and solvent on the diene no. of a hydrocarbon mixt., especially a mixt. of cracked products. To prevent polymerization and the possibility of reaction between ethylenic hydrocarbons and maleic anhydride it is essential that the reaction temp. be kept below 100°. Inconsistent results were obtained with reaction times varying from 5 to 30 hrs. but in general the diene no. increased with increasing time. Maleic anhydride is used preferably in a concn. of 0.2 *M*. The best solvent appears to be xylene. Unreliable results are reported with toluene. 11 tables and 15 references.

E. J. Mahler

Halogenation of hydrocarbons. Chlorination of olefins and olefin-paraffin mixtures at moderate temperatures; induced substitution. H. P. A. Groll, G. Hearne, F. F. Rust and W. E. Vaughan. *Ind. Eng. Chem.* **31**, 1239-44 (1939).—Flow studies on the chlorination of olefins have revealed that analyses for free halogen in olefin-Cl mixts. are susceptible to error because of the possibility that catalyzed reactions may occur in the absorption vessel. It has been proved that olefins react with Cl only slowly, if at all, in the gas phase at moderate temps. (below 150°). In the presence of a liquid phase, however, the reactions are exceedingly rapid. Under this condition the substitution of Cl into the satd. addn. product or into a concurrently present paraffin is inhibited by O, the paraffin reaction being the more strongly influenced. These substitution processes come under the classification of "induced" reactions. The distribution of products from several such chlorination reactions has been detd. Catalytic vapor-phase chlorination of olefins and of olefin-paraffin mixts. occurs at moderate temps. in the absence of liquid. The concurrent substitution reactions are not inhibited by O and are a consequence of purely thermal and catalytic conditions rather than induction. William E. Vaughan

Halogenation of hydrocarbons. Substitution of chlorine and bromine into straight-chain olefins. H. P. A. Groll and G. Hearne. *Ind. Eng. Chem.* **31**, 1530-7(1939); cf. preceding abstr.—The reaction of halogens with olefins contg. a double bond in an unbranched C chain is

changed from addn. to substitution by operating at elevated temps. This substitution, unlike so-called "induced substitution," occurs exclusively into the olefin with the formation of allyl-type unsatd. monohalides. The optimum temp. ranges from 300 to 600°, depending on the nature of the olefin and halogen. Operating conditions have been examd. in some detail so that the work can serve as a basis which will make this class of products easily available. E. g., chlorination of propylene at 500° resulted in 74% of unsatd. monohalide, principally allyl chloride. Bromination yields allyl bromide. Other hydrocarbons were also studied. William E. Vaughan

Hydrogenation of 1-heptene and heptane under hydrogen pressure. A. F. Nikolaeva and P. V. Puchkov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 345-6(1939)(in English).—Heptane (I), b_{745} 96-8°, n_D^{20} 1.3880, d_{20} 0.6844, $PhNH_2$ point 70.0°, from the dehydration of heptyl alc. to give 1-heptene (II) and subsequent hydrogenation at room temp. by Skita's method, reacts with HNO_3 in a sealed tube at 120° to give 2-nitroheptane, n_D^{23} 1.4240, 98% sol. in KOH soln. on heating. I (40.6 g.), heated 2 hrs. at 400° under 140 atms. H in the presence of 4.0 g. MoS_2 and the product distd., gave fraction *a*, b. 78-95.5° (11.0 g.), n_D^{20} 1.3860, d_{20} 0.6798, $PhNH_2$ point 70.6°; fraction *b*, b. 95.5-8.2° (17.3 g.), n_D^{20} 1.3880, d_{20} 0.6845, $PhNH_2$ point 70.6; residue n_D^{20} 1.4038. Fraction *a* heated 24 hrs. in a sealed tube at 120° with HNO_3 gave a product, n_D^{20} 1.4262, 60% sol. in KOH soln. The undissolved nitro compds., n_D^{20} 1.4276, reduced with Sn and HCl gave an oil with an ammoniacal odor, proving that I had isomerized to give isoheptanes. II (37.5 g.), b. 94-8°, n_D^{20} 1.4051, d_{20} 0.7029, heated 40 min. at 400° under 90 atms. of H in the presence of 3.7 g. MoS_2, is completely hydrogenated (value 0.7). On distn. the product gave fraction *a*, 80-94° (5.6 g.), n_D^{20} 1.3848, d_{20} 0.6790, $PhNH_2$ point 71.4°; fraction *b*, b. 94-8° (19.9 g.), n_D^{20} 1.3880, d_{20} 0.6893, $PhNH_2$ point 71°; residue, n_D^{20} 1.4119. The mol. wt. of fraction *a* is 101, i. e., no polymerization and no splitting of the mols. have occurred but the phys. consts. show that isoheptanes are formed in this case also.
Janet E. Austin

Action of elementary fluorine on organic compounds. VI. The vapor phase reaction between ethane and fluorine in progressively varying proportions. John D. Calfee, Nobukazu Fukuhara and Lucius A. Bigelow. *Jr. Am. Chem. Soc.* **61**, 3552-4(1939); cf. *C. A.* **32**, 2519[1].—The app. for the fluorination and the low-temp. distn. is described and illustrated. The vapor-phase fluorination of C_2H_6 (IV) over a Cu-gauze catalyst gives CF_4 (I), azeotropes A (II) and B (III), IV, C_2F_6 (V) and a residue b. above −78° (VI). III b. −92°, mol. wt. 62; this consists of approx. 2:1 IV and V. II b. −104°, mol. wt. 54, and consists of approx. 6:1:1 of IV, V and SiF_4. The liquid vol. % of products using 1:1, 2.3:1, 4:1 and 6:1 ratios, resp., of F and IV are: I, 5, 12, 21, 12; II, 11, 17, 21, 18, III, 31, 52, 14, 0; IV, 42, 0, 0, 0; V, 0, 6, 32, 41; VI, 12, 17, 14, 29. As the proportion of F in the reaction mixt. increases the quantities of I and V increase, while the amt. of IV recovered decreases. III was formed in max. quantity under conditions when both of its components would be expected to be present in considerable proportions at the same time. Direct fluorination is more similar to chlorination than has been supposed hitherto.
C. J. West

Chlorinations with sulfuryl chloride. II. The peroxide-catalyzed reaction of sulfuryl chloride with ethylenic compounds. M. S. Kharasch and Herbert C. Brown. *J. Am. Chem. Soc.* **61**, 3432-4(1939); cf. *C. A.* **33** 7728[8]. —SO_2Cl_2 reacts with ethylenic compds. to form the corresponding dichlorides; the reaction is catalyzed by org. peroxides; it is suggested that the reaction proceeds through a chain mechanism involving atoms and free radicals. Cyclohexene and SO_2Cl_2 in CCl_4 give about 90% of dichlorocyclohexane; allyl chloride gives 80-90% of 1,2,3-trichloropropane; ClCH:CHCl gives 85% of $Cl_2CHCHCl_2$ in the presence of Bz_2O_2; stilbene gives 45% of the α,α′-dichloride and 33% of the β,β′-isomer; Cl_2C:CCl_2 gives 15% of Cl_3CCCl_3 in 5 hrs.; Ph_2C:CPh gives the dichloride (the reaction is very slow in the absence of the peroxide).
C. J. West

Hydrogen bonds involving the C—H link. VIII. The solubilities of completely halogenated methanes in organic solvents. M. J. Copley, G. F. Zellhoefer and C. S. Marvel. *J. Am. Chem. Soc.* **61**, 3550-2(1939); cf. *C. A.* **34**, 396[6].—Soly. data are given for CCl_2F_2 and CCl_3F at 32.2° at pressures equal to their vapor pressure at 4.5° in hexyl alc., cyclohexanol, PhOH, $(CH_2OH)_2$, $CH_3(CH_2OH)_2$, cyclohexyl Me ether, PhOMe, $MeO(CH_2CH_2O)_4Me$, AcOH, $EtCO_2H$, Et laurate, Et caprylate, heptaldehyde, cyclohexanone, Ac_2CH_2, $(AcCH_2)_2$, cyclohexylamine, $PhNH_2$, dimethylcyclohexylamine, $PhNMe_2$, quinoline, $AcNH_2$, AcNHMe, $AcNMe_2$, BuCN, PhCN, EtMeC.NOH, decane, mesitylene, PhBr and hexyl bromide. In practically every case the soly. was lower than that calcd. from Raoult's law. These observations support the earlier postulation that intermol. assocn. through H bonding is an important factor in producing soly. of H-contg. halogenated methanes. C. J. West

Mechanism of the hydrolysis of α,γ-dimethylallyl chloride. C. L. Arcus and J. W. Smith. *J. Chem. Soc.* **1939**, 1748-9.—The hydrolysis of α,γ-dimethylallyl chloride (I) in aq. Me_2CO (75% by vol.) has been followed by a conductometric method and shown to follow a unimol. law, in accord with the mechanism deduced from stereochem. observations. The apparent incompleteness (93%) of the reaction in the cond. cell employed is attributed to adsorption of the I on the Pt-blacked electrodes.
C. J. West

Structure of vinyl polymers. VI. Polyvinyl halides. C. S. Marvel, J. H. Sample and Max F. Roy. *J. Am. Chem. Soc.* **61**, 3241-4(1939); cf. *C. A.* **34**, 3748.—Heating a satd. soln. of polyvinyl chloride (I) in dioxane with Zn gives an insol. product still contg. most of the Cl. When a very dil. soln. of I in dioxane was used the cross-linking reaction which produced the insol. material was avoided and a smooth dehalogenation reaction occurred; under the most favorable conditions the dehalogenated product (II) contained 13 to 16% Cl (i. e., I had lost 84-87% Cl); under similar conditions the bromide polymer (III) lost 85.9% Br; Flory (*C. A.* **33**, 6236[3]) has shown that random removal of pairs of halogens in a polymeric 1,3-dihalide should take out 86.47% of the halogen and leave 13.53% isolated from reactive neighbors and non-removable except by cross-linking of the C chains. II is sol. in dioxane, does not decolorize alk. $KMnO_4$ and in CCl_4O_3 shows no evidence of ozonolysis; HNO_3 does not give cryst. oxidation products. With Cl both addn. and substitution occur. Neither I nor III liberates I from a peroxide-free dioxane soln. of KI. Treatment of a Cellosolve soln. of I with KOH removes halogen acid and leads to the formation of an insol. shiny reddish brown polymer. The ultraviolet absorption spectrum of I is very similar to that of 2,4-dichloropentane and somewhat different from that of the 2,3-isomer. All these facts support the view that I has the 1,3-dihalide structure. **VII. Polyacrylyl chloride.** C. S. Marvel and Charles L. Levesque. *Ibid.* 3244-6.—Acrylyl chloride, prepd. from Na acrylate and $POCl_3$, may be polymerized either by peroxides or ultraviolet light; when $SOCl_2$ is substituted for $POCl_3$ the product obtained is polymerizable only by ultraviolet light (the chloride may be contaminated with a little $SOCl_2$ which inactivates the peroxide catalyst). The polymers (I) obtained are brittle, pale-yellow solids, sol. in $POCl_3$ and dioxane but insol. in other common solvents. Photopolymerized I with Br gives a Br compd. contg. 1 atom Br for every 3.4 I units; transformed into the Me ester and heated with KI in Me_2CO it gives free I equiv. to 46% of the Br in the polymer; this reaction is characteristic of 1,2-di-Br compds., especially those in which the Br atoms are adjacent to a neg. group. The production of 1,2-di-Br units is most logically explained by assuming a "head-to-head, tail-to-tail" structure for this polymer. Since only a third of the H atoms in the α-positions of I were replaced by Br, the possibility of the presence of some "head-to-tail" units is not excluded. No bromination occurs with polymethacrylyl chloride, in which the α-positions are not

available for substitution. These facts indicate that at least a part of the units of I are arranged in a "head-to-head, tail-to-tail" structure, [—$CH_2CH(COCl)CH(COCl)CH_2CH_2CH(COCl)CH(COCl)CH_2$—]$_n$. C. J. W.

Polarizations and related data of optically active and racemic β-octanols. J. B. M. Coppock and F. R. Goss. *J. Chem. Soc.* **1939**, 1789–92.—Detns. of the d., dielec. const., mol. polarization and partial polarization in C_6H_6 of *d*-, *l*- and *dl*-β-octanol reveal no difference between the active and the *dl*-forms. These results are in agreement with the view that the *dl*-compd. is simply a racemic mixt. It is shown that the hygroscopic nature of the carbinol leads to anomalous results for the moist material and the need for the careful exclusion of H_2O in the measurements described is emphasized. The apparent dipole moment of β-octanol in C_6H_6 is 1.66 D. The *d*-alc. has [α] 9.91°, 10.38°, 11.64° and 19.2° at 5893, 5780, 5461 and 4358 A.; the values for the *l*-alc. are −9.72°, −10.09°, −11.48° and −19.2°; d_4^{20} is 0.8202 and 0.8201 for the *d*- and *l*-alcs.; all 3 isomers have n_D^{20} 1.4264. The ε value for *dl*-alc. immediately after distn. is 8.173; addn. of 0.2% H_2O gives 7.982; after standing 1 month, 8.120; after 6 months, 7.785. C. J. West

Optical activity of α-bromopropionitrile. Kenneth L. Berry and Julian M. Sturtevant. *J. Am. Chem. Soc.* **61**, 3583–4(1939). In connection with recent theories of optical rotatory power, *l*-MeCHBrCN (I) has been prepd. by asym. conversion from *l*-MeCHBrCO$_2$H (II). The rotation of II indicated it to be 67.1% *l*- and 32.9% *d*-acid; the I, prepd. by dehydration of the amide with P_2O_5, had $[\alpha]_D^{25}$ −5.25°; on the assumption that no racemization occurred during the synthesis the calcd. $[\alpha]_D^{25}$ for I is −15.33°. Efforts will be made to prep. a purer I. C. J. West

Preparation of primary amines. Alexander Galat and Gertrude Elion. *J. Am. Chem. Soc.* **61**, 3585 6(1939).—One mole of hexamethylenetetramine in 8 10 times its wt. of hot 95% EtOH and slightly more than 1 mole of NaI, treated with 1 mole alkyl chloride or bromide, gives the amine on standing (varying from a few min. to several weeks); the longer the C chain the longer is the time required for pptn. The amine is pptd. by satn. of the mixt. with HCl gas and liberated by distn. with excess of NaOH. $MeNH_2$, 1 week, 72%; $EtNH_2$, 8 days, 82.5%; $PhCH_2NH_2$, 2 hrs., 82.5%; *p*-$O_2NC_6H_4CH_2NH_2$, 1 day, 61%; $PhCH_2CH_2NH_2$, 3 weeks, 54%. C. J. West

Preparation of certain amines. Edward J. Schwoegler and Homer Adkins. *J. Am. Chem. Soc.* **61**, 3499 502 (1939).—Conditions have been detd. for the max. yields of secondary and tertiary amines from alcs. and amines. Equimol. quantities (usually 0.2 mole) of amine and alc. and 4 g. Cu chromite were used except in (*i*) where 3–4 g. Raney Ni and in (*f*) and (*j*) where 8 g. Cu chromite were used; 80 ml. of dioxane was the solvent for 0.2 mole amine except in (*c*) where an excess of alc. and (*a*) and (*g*) where Et_2O was the reaction medium. All reactions were carried out under 125 atm. of H at the temps. and for the times indicated: (*a*) and (*e*) 12 hrs. at 180°; (*b*) and (*c*) 3.5 hrs. at 200°; (*i*) 12 hrs. at 250°; (*d*) and (*f*) 3.5 hrs. at 250°; (*g*), (*h*) and (*j*) 12 hrs. at 200°. The alc. and methods used and yields (%) of amines are given. $AmNH_2$: EtOH, (*a*) 39; PrOH, (*a*) 15; iso-PrOH, (*a*) 43; BuOH, (*a*) 6; cyclohexyl alc. (I), (*e*) 57; dodecyl alc. (II), (*a*) 0. Piperidine (III): EtOH, (*c*) 82; EtOH, (*d*) 31; PrOH, (*d*) 63; iso-PrOH, (*d*) 46; BuOH, (*g*) 70; BuOH, (*f*) 83; hexyl alc., (*d*) 84; I, (*d*) 59; 2-ethylhexyl alc., (*i*) 29; II, (*c*) 69; (*d*) 78. Phenethylamine: EtOH, (*b*) 67; PrOH, (*b*) 26; iso-PrOH, (*b*) 67; BuOH, (*b*) 60; I, (*b*) 58; II, (*b*) 14. *2-Methyl-4-aminopentane* (IV): EtOH, (*g*) 53; PrOH, (*a*) 61; iso-PrOH, (*a*) 50; BuOH, (*j*) 48; I, (*h*) 37; II, (*h*) 47. The high yields with III are due to the higher temps. used; their use, as contrasted with primary amines, is possible because the latter may form secondary amines through dehydrogenation. Representative ketones and aldehydes have been converted in good yields to the corresponding primary amines by soln. in a mixt. of MeOH and liquid NH_3 and hydrogenating over Raney Ni; the reaction mixt. in most cases consisted of 0.5 mole CO compd., 0.7 mole of NH_3, 50 ml. of MeOH and 3–4 g. of Raney Ni under 150 atm. of H; except for BzH (125°) and furfural (125–40°) the reaction temp. was 150°; the time was usually about 1 hr., though with furfural the reaction was complete after 10 min., whereas Ph_2CO was heated for 3.5 hrs. before the absorption of H ceased. Among the compds. which have given good results are heptaldehyde, BzH, PhAc, pinacolone and several dialkyl ketones. The yields (%) of various amines were as follows: IV 65, α-phenethylamine 64, benzohydrylamine 19, *2,2-dimethyl-3-aminobutane* (V) 51, 5-aminononane 72, *2,4-dimethyl-3-aminopentane* (VI) 48, $PhCH_2NH_2$ 48, heptylamine 59, furfurylamine 60. Acetonylacetone under the same conditions gives *2,5-dimethylpyrrolidine* (VII) 28 and 2,5-dimethylpyrrole 59; Ac_2CH_2 gives a quant. yield of $AcNH_2$. Hydrogenation of BuCN and hexyl cyanide in the presence of NH_3 at 125° over Raney Ni gives less than 5% of secondary amine and 90–5% of primary amines. *N-2-Ethylhexylpiperidine*, b_{42} 141°, *n* 1.4520 (all values at 20° for n_D) (*HCl salt*, m. 162–3°); *N-propyl-β-phenethylamine*, b_{16} 102°, *n* 1.4998 (*HCl salt*, m. 218°); *N-iso-Pr isomer*, b_{21} 112°, *n* 1.4990 (*HCl salt*, m. 163–4°); *N-ethylamylamine*, b. 136°, *n* 1.4111 (HCl salt, m. 195°); *N-propylamylamine*, b. 155°, *n* 1.4161 (*HCl salt*, m. 247° (decompn.)); *N-isopropylamylamine*, b. 146°, *n* 1.4113 (*HCl salt*, m. 167–7.5°); *N-cyclohexylamylamine*, b_{30} 118°, *n* 1.4500; *N-ethyl-2-methyl-4-aminopentane*, b. 136°, *n* 1.4105 (*HCl salt*, m. 144–5°); *N-propyl-2-methyl-4-aminopentane*, b. 162°, *n* 1.4148 (*HCl salt*, m. 139°); *N-Bu analog*, b. 179°, *n* 1.4192 (*HCl salt*, m. 149–50°); *N-dodecyl analog*, b_{12} 170–2°, *n* 1.4410 (*HCl salt*, m. 124.5 5°); *N-cyclohexyl analog*, b_{21} 106°, *n* 1.4530 (*HCl salt*, m. 198–9°); *PhNCO derv.*, m. 110°); *N-iso-Pr analog*, b. 146°, *n* 1.4098 (*HCl salt*, m. 158.5°); IV, b. 108 9°, *n* 1.4063 (*HCl salt*, m. 139.5°); *N-ethyl-β-phenethylamine*, b_8 85° (*HCl salt*, m. 183.5–4°); *N-butyl-β-phenethylamine*, b_6 113.5°; V, b. 102° (*HCl salt*, m. 296–7° (sublimation)); VI, b. 129° (*HCl salt*, m. 196°); VII, b. 113–18° (*HCl salt*, m. 201–2°); *isopropylpiperidine picrate*, m. 153°. C. J. West

Action of diazomethane on zinc chloride. G. Caronna and B. Sansone. *Atti X° congr. intern. chim.* **3**, 77–81 (1939).—One mol. $ZnCl_2$ (I) in 2 mols. abs. ether (II) was added dropwise to 1.0 g. CH_2N_2 (III) in II until the III was no longer discolored. The gas evolved (832 cc. at 0°, 760 mm.) was collected. From the vol. of gas evolved and from the fact that $(CH_2OH)_2$ was detected on treating the residual soln. with Ag_2O, the reaction is believed to proceed according to the equation $Et_2O + ZnCl_2 + 2CH_2N_2 = ZnO + C_4H_{10} + C_2H_4Cl_2 + 2N_2$. The complex Zn alkyl, $Zn(CH_2Cl)_2$ is believed to be an unstable intermediate product which then reacts with II to give the final products. J. C. Lo Cicero

Preparation of Grignard reagents from magnesium amalgams. Eugene G. Rochow. *J. Am. Chem. Soc.* **61**, 3591(1939). The yield of RMgX from Mg-Hg increases with the concn. of Mg in the amalgam and with the increasing possibility of free Mg in the mixt.; 0.1, 0.5 and 1% Mg in the amalgam give 0, 4.1 and 25.3% RMgX. It may be concluded that $MgHg_2$ does not participate in the Grignard reaction as readily as Mg and that Hg therefore has an inhibiting effect on the reaction. C. J. W.

Redistribution reaction. IV. Interchange between triethyllead chloride and radioactive tetraethyllead. Geo. Calingaert, Harold A. Beatty and Lewis Hess. *J. Am. Chem. Soc.* **61**, 3300–1(1939); cf. *C. A.* **34**, 373⁹.—With Ra D as an indicator, it is shown that an interchange of Cl atoms and Et radicals between $PbEt_4$ and $PbEt_3Cl$ takes place and reaches equil. in less than 1 day at room temp. C. J. West

Oxidation of aldehydes. I. The combustion zones of butaldehyde, isobutaldehyde, propaldehyde, acetaldehyde, glyoxal and acraldehyde. D. M. Newitt, L. M. Baxt and V. V. Kelkar. *J. Chem. Soc.* **1939**, 1703–10; cf. *C. A.* **32**, 1167⁹, 1168⁴,⁶.—The combustion zones of a series of satd. and unsatd. aldehydes have been mapped out over a wide range of temps. and pressures. A compari-

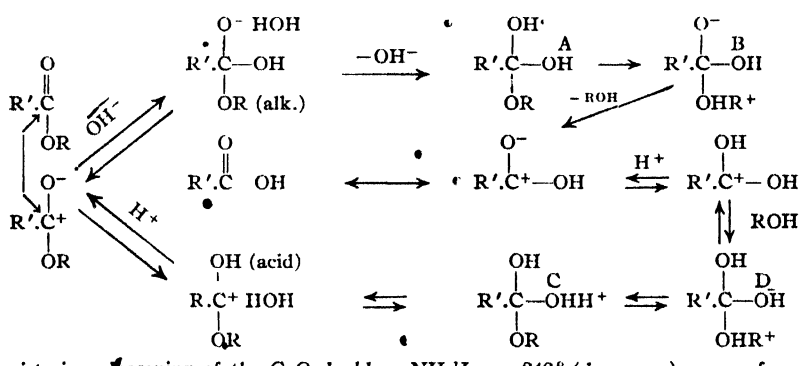
son of the combustion diagrams indicates that the order of reactivity of the satd. aldehydes with respect to O depends upon the compn. of the reacting medium and upon its temp. and pressure. The effect of a side chain is to increase the resistance of the aldehyde to O attack and the presence of a double bond alters the character of the combustion in such a way as to suggest that the processes occurring at low temps. result in a slower building up of the critical concn. of the particular species responsible for cool-flame inflammation. Mixts. contg. 9–20% of aldehyde and 91–80% of (2N + O) are suitable, the proportions being varied according to the no. of C atoms in the aldehyde. Combustion diagrams are given for EtCHO, PrCHO, iso-PrCHO, AcH, $(CHO)_2$ and CH_2:CHCHO. The existence of 3 pressure limits of normal ignition are observed in the case of the satd. aldehydes. The original should be consulted because the diagrams cannot be described adequately in an abstract. **II. The products of their combustion.** D. M. Newitt and L. M. Baxt. *Ibid.* 1711–20.—The oxidation products of a series of satd. and unsatd. aldehydes have been studied over a wide range of conditions from slow combustion to normal ignition. During the oxidation of EtCHO and AcH the initial product consists of a relatively stable peroxide (I), isomeric with the corresponding per acid. This substance, which is found at all stages prior to cool-flame inflammation or normal ignition, decomps. to give a 2nd peroxide (II) and an ale., in aq. soln. it changes into a per acid. The incidence of cool flames and normal ignition are shown to be conditioned by its presence in critical concns. There is no evidence that per acids or acids are formed in an excess aldehyde-O medium during reaction, except at low temps. At higher temps. some step-wise oxidation of aldehydes takes place to give lower members of the series. Data are given for C_4H_6, AcH, EtCHO, $(CHO)_2$ and CH_2:CHCHO. C. J. West

Aldehydic odoriferous substances. II. Synthesis of pelargonaldehyde. Seiiti Isikawa and Akira Miyata. *Science Repts. Tokyo Bunrika Daigaku* **A3**, 257–63(1939) (in German), cf. *C. A.* **31**, 7851[4]. Pelargonaldehyde, $Me(CH_2)_7CHO$ (I), is obtained in 20% yield by passing ozonized air into a suspension of oleic acid, $Me(CH_2)_7CH$:$CH(CH_2)_7CO_2H$, in aq. $NaHSO_3$ to which a small amt. of decalin has been added. Under other conditions (cf. Kobata, *C. A.* **29**, 7279[2]) the yield of I is even smaller. Pelargonic acid and azelaic semialdehyde, $CHO(CH_2)_7CO_2H$ (II), are formed in addn. to I. Better yields (50%) of I and 53% of the Me ester of II are obtained by adding 10 g. mixt. to 40 g. Me 9,10-dihydroxystearate, $Me(CH_2)_7CH(OH)CH(OH)(CH_2)_7CO_2Me$ (III), (from castor oil) in 400 cc. glacial AcOH and 10 cc. Ac_2O. Small amts. of I are also formed (beside a substance m. 42–3°) by heating III in the presence of sea sand in a CO_2 atm. to 650°. I b_{22} 91.2°, d_{16} 0.8280, n_D^{18} 1.4274; 2,4-dinitrophenylhydrazone, m. 106–7°. The Me ester of II b_{18} 135–9°, d_{20} 0.9542, n_D^{18} 1.43705; 2,4-dinitrophenylhydrazone, m. 67.8°. Dora Stern

Chloralides. Condensation of butylchloral with α-hydroxy carboxylic acids. N. M. Shah. *J. Indian Chem. Soc* **16**, 285–6(1939).—A mixt. of 25 g. citric acid, 25 g. butylchloral hydrate (I) and 50 cc. concd. H_2SO_4 was shaken together and after 24 hrs. poured onto ice. The brown residual mass was dissolved in AcOH, treated with concd. HCl and recrystd. from Et_2O and petr. ether yielding 8 g. of *citric acid butylchloralide*, $C_{10}H_{11}Cl_3O_7$, m. 187–8°. Similarly were prepd. the *malic* and *tartaric acid butylchloralides*, $C_8H_9Cl_3O_6$ and $C_{12}H_{12}Cl_6O_6$, m. 139 and 156°, resp. The yields (2 g.) were uniformly poor and no monocondensation product with tartaric acid was formed. Attempts to form butylchloralides from mandelic and benzilic acids were unsuccessful. No product was obtained by reduction of the butylchloralides with Zn dust and AcOH. C. R. Addinall

Crotonaldehyde condensation. Reaction of crotonaldehyde with formamide. Hans L. du Mont and Werner Schmidt. *Ber.* **72B**, 2029–35(1939).—This paper deals with the resins obtained in the condensation of crotonaldehyde (I) with amides, such as $HCONH_2$ (II), to form pyridine (*C. A.* **33**, 8171[6]). The question was by what conditions of temp., pressure, concn. and catalyst the reaction is influenced and what is the nature of the products formed in addn. to pyridine. The N content of these products, obtained often under very different conditions, varies within narrow limits (5.5–6.5%). Many of the air-dried resins contain about 4% moisture which can be removed *in vacuo* over P_2O_5. The removal of inorg. constituents is more difficult and often cannot be effected quantitatively so that the results of analysis have to be recalcd. on the basis of the ash-free org. substance. The empirical formulas so obtained ($C_8H_{13}ON$ or $C_8H_{12}ON$, $C_{10}H_{15}ON_6$, $C_{10}H_{16}ONCl$, $C_{12}H_{17}ON$, $C_{14}H_{17}O_3N$, $C_{14}H_{24}O_2N_2Br_2$, $C_{15}H_{26}O_8N_2Cl_2$, $C_{20}H_{28}O_2N_8$, $C_{20}H_{30}O_2N_2$, $C_{20}H_{32}O_2N_2Cl_2$, $C_{28}H_{48}O_4N_4Br_4$, $C_{38}H_{45}O_6N$) almost all contain an even no. of C atoms although an odd no. of C atoms would have been expected in condensation products of I and II. This suggests that these resins are formed for the most part from I and NH_3 resulting from decompn. of the II; this would explain the C_8-, C_{12}- and C_{20}- compds.; the mol. wts. of the C_{10}- and C_{14}- compds. are either to be doubled or these compds. are to be considered as condensation products of I with AcH resulting from decompn. of the I. In the condensations the temp. was varied between 20° and 180°, the pressure between 1 and 40 atm., the reaction time between 1 hr. and 2 weeks, the ratio of I to II between 2:1 and 1:2. As solvents were employed water, MeOH, dioxane and benzene, or no solvent was used. As dehydrating agents and catalysts were used K_2CO_3 and U oxide, $ZnCl_2$, $AlCl_3$ or $CdCl_2$.$ZnCl_2$ exerted a catalytic action only when used in large amts., but its use resulted in a lower and a more vigorous and complete reaction. The condensation does not proceed like the autocondensation of I catalyzed by piperidine, which takes place suddenly and rapidly and, even in the presence of II, yields only N-free products as resins. Details of the prepn. and the analytical results on the compds. listed above are given. C. A. R.

Catalytic action of vanadium compounds in the conversion of acetylene and water vapor to acetone. D. Cozzi. *Atti X° congr. intern. chim.* **3**, 89–94(1939).—The use of a mixt. of $Zn_3(VO_4)_2$ (I) and $Mn_3(V_3O_8)_2$ in the ratio of 1:1 gives a yield in excess of 90% of Me_2CO from C_2H_2 and H_2O and the temp. required is 50° lower than that necessary if the simple oxides were used as catalyst. The H_3VO_4 apparently acts as an activator for the ZnO in converting the HOAc (an intermediate product in the reaction) to Me_2CO. J. C. Lo Cicero



The melting-point curve of esters of dihydroxystearic acid from castor oil. Seiiti Isikawa and Eiiti Kuroda. *Science Repts. Tokyo Bunrika Daigaku* **A3**, 265–71(1939) (in German).—The esters of dihydroxystearic acid from castor oil with 14 normal primary alcs. are synthesized, using $PhSO_2Cl$ or H_2SO_4 as condensing agent. With regard to their m. ps. the esters of alcs. with an even, and those with an uneven no. of C atoms form 2 different series, the m. ps. of the 1st series being lower than those of the second. The hexyl ester has the lowest m. p. The differences between the m. ps. of 2 subsequent esters decrease with increasing C atoms. The esters up to the dodecyl ester are cryst., the tetradecyl, hexadecyl and octadecyl esters are waxy amorphous substances, insol. in water and ether, difficultly sol. in alc. and benzene and easily sol. in CCl_4. The m. ps. of the esters, detd. according to Berl (cf. *C. A.* **21**, 3285), are the following: *Me* 110°, *Et* 100°, *Pr* 100.6°, *Bu* 93°, *Am* 93.7°, *hexyl* 92.2°, *heptyl* 94.3°, *octyl* 93.4°, *nonyl* 95.4°, *decyl* 94.9°, *dodecyl* 95.6°, *tetradecyl* 96.6°, *hexadecyl* 97.4°, *octadecyl* 98.2°. The heptyl alc. employed, prepd. by reducing enanthal, b. 175–6°, d_4^{20} 0.8239, n_D^{20} 1.4356. The decyl alc., obtained by hydrogenizing coconut oil under high pressure and fractionating, b_9 113–15°, d_4^{20} 0.8275. Dora Stern

Pseudoeleostearic acid. J. P. Kass and G. O. Burr. *J. Am. Chem. Soc.* **61**, 3292–4(1939).—The linseed oil fatty acids from which the solid acids were removed by 2 crystns. from ligroin at −18° (625 g.) are refluxed under N for 2 hrs. with an equal wt. of KOH in 2.5 l. anhyd. $(CH_2OH)_2$ (or BuOH); the mixt. is cooled, several hun-

dred cc. of H_2O added and the mixt. again refluxed to saponify the esters; the soln. is esterified, the acids extd. with 1.5 l. ligroin and washed with H_2O; at −18° 25 g. pseudoeleostearic acid (I) seps. (cf. Moore, *C. A.* **31**, 4517[8]). I seps. from 85% EtOH as feathery crystals and from hexane as glistening scales; at 0° 1 g. I requires 175 cc. petr. ether (30–5°) for soln. I m. 77–9° and is remarkably susceptible to oxidation, quickly acquiring an acridly rancid odor and even its ligroin soln. becomes opalescent on boiling. The I no. gives values intermediate between 2 and 3 double bonds, rising with time. Catalytic reduction of I gives stearic acid. The Me ester (II) of I m. 41°. Oxidation of II with $KMnO_4$ in Me_2CO (boiling 3 hrs.) gives sebacic acid, $(CO_2H)_2$ and $PrCO_2H$, establishing its structure as *10,12,14-octadecatrienoic acid*. I (1.5 g.) in 250 cc. petr. ether at 0°, treated with Br until a distinct orange color results, gives after 3 hrs. about 0.1 g. of a *tetrabromide*, $C_{18}H_{30}O_2Br_4$, m. 104–4.5°; addn. of Br to the filtrate and exposure to direct sunlight at room temp. for 24 hrs. give 90 mg. of a *hexabromide* (III), m. 152–2.5°; the only other products are liquid bromides; III is apparently the only solid product obtained on bromination in ultraviolet light; this light induces no isomerization of the I. The maleic anhydride addn. product is not homogeneous and could not be sepd. into clearly defined individual components; this points to the geometric configuration of the parent acid as the trans-trans-trans or trans-cis-trans isomer, either 1 of which may form more than 1 condensation product. C. J. West

New method for the cleavage of unsaturated aliphatic acids. Chi-Yi Hsing and Kou-Jen Chang. *J. Am. Chem. Soc.* **61**, 3589(1939).—Shaking 0.6740 g. of 9,10-dihydroxyoctadecanoic acid (from oleic acid) and 0.95 g. $Pb(OAc)_4$ in 10 cc. AcOH for 24 hrs. gives 90% of azelaic semialdehyde (I) and 82% of pelargonic aldehyde (isolated as the semicarbazones). In C_6H_6 9,10,12-trihydroxyoctadecanoic acid (from ricinoleic acid) is oxidized in 4 hrs., giving about 90% of I and a semicarbazone, m. 112–13°, which may be β-hydroxypelargonic aldehyde semicarbazone. C. J. West

Mechanism of ester saponification and ester formation. Otto Mumm. *Ber.* **72B**, 1874–8(1939).—The scheme given by Hinshelwood and co-workers (*C. A.* **33**, 1199[6], and earlier papers) to represent the mechanism of ester sapon. does not sufficiently take in the individual stages of the reaction and M. accordingly suggests the following scheme:

The 1st step consists in a loosening of the C:O double bond, i. e., a shifting of the mesomerism in the direction of the zwitter-ion form. Then, in alk. sapon., the now pos. charged C atom adds a HO ion, while in acid sapon. the neg. O atom binds a proton. At the same time the remaining charge, of opposite sign, of the loosened ester mol. attracts a water mol. because of its polar character and binds it, at the pos. C atom in acid sapon. and at the neg. O atom in alk. sapon., in the latter case repelling a HO ion. This process probably dets. the velocity of the reaction. The assumed migration of a proton from the one to the other O atom with formation of an oxonium ion (A → B) or with mutual interconversion of 2 oxonium ions (C → D) probably occurs intramol. through an intermediate stage with a "H bond." If this mechanism is correct, it should be possible to detect one or other of the intermediate stages by trapping it by means of a suitable reaction. This, because of their reactivity, should be especially true of the carbenium cations formed in the course of the acid sapon. and also of the zwitter-ion formed in the next to the last stage of both acid and alk. sapon. The life of this zwitter-ion is very short, to be sure, but in its stabilization to the acid there also occurs a change in the positions of the atoms toward each other which must require a certain length of time, sufficient, even if but extraordinarily short, for the detection of the zwitter-ion. Support for this is afforded by the recent observations of the change in alk. medium of pyridone methides into a peculiar bicyclic system (*C. A.* **32**, 9085[7]) and of the surprising migration of the C_5H_9 group in 3,2-Me(CH₂:CHCHEtO)$C_6H_3CO_2Me$ to the *p*(5)-position on alk. sapon. (*C. A.* **33**, 8185[9]). C. A. R.

Optical activity dependent on the planar arrangement of the valencies of the 4-coördinated palladous atom. Alan G. Lidstone and Wm. H. Mills. *J. Chem. Soc.* **1939**, 1754–9.—The method employed by Mills and Quibell (*C. A.* **29**, 5764[1]) for the examn. of the valency configuration of the 4-covalent Pt atom has been applied to Pd. The planar configuration of the valencies of Pd (4-covalent Pd atom) has been inferred from 2 kinds of evidence—the occurrence of isomerism in various Pd compds. in which a planar arrangement of the valencies would require the existence of geom. isomerism and the x-ray analysis of the crystal structure of various Pd compds. The following work furnishes a 3rd line of evidence. A 13% aq. soln. of isobutylenediamine (2 moles, 210 cc.) is dild. with 500 cc. H_2O, heated to 80–90° and 1 mole (500 cc.) of 10% aq. K_2PdCl_4 added during 10 min. and the mixt. heated until clear; 50 cc. coned. HCl were added and the soln. heated 10 min.; on cooling 85–90% of *isobutylenediaminodichloropalladium* (I), $H_2N.CMe_2.CH_2.NH_2.PdCl_2$, seps. as orange prisms, decompg. about 300°

I (25 g.) is boiled with 500 cc. H_2O and a satd. EtOH soln. of 20 g. mesostilbenediamine (IA) gradually added; 32.5 g. KI are then added and the soln. cooled to 0°; 90% of *dl-isobutylenediaminomesostilbenediaminopalladous iodide* (II), $[H_2N.CMe_2.CH_2.NH_2.Pd.NH_2.CHPh.CHPh.NH_2]I_2$, m. 242° (decompn.) seps.; from a dil. aq. soln. a *hydrate* (1 H_2O) seps. II (25 g.), shaken with the Ag_2CO_3 from 18 g. $AgNO_3$ for 1 hr., the filtrate treated with 8.15 g. *d*(−)-diacetyltartaric anhydride, the soln. evapd below 50° and the residue pptd. from a small quantity of H_2O by abs. EtOH gives a mixt. of the *d*- and *l*-salts, hygroscopic needles with 2 moles of H_2O; digestion of 75 g. with 60 cc. cold H_2O and 200 cc. abs. EtOH, filtration, addn. of 500 cc. abs. EtOH to the filtrate and repetition of the operation give 18 g. of *l*-II *d*(−)-*diacetyltartrate* (III) as the *dihydrate*; the anhyd. III shows $[M]^{15}_{5461}$ −120.5°, −117°, −113°, −111°, −110° with *c* 9.97, 6.33, 4.22,

1.944, 1.25. III with KI in H_2O gives the *iodide*, which with $AgNO_3$ gives the *nitrate* (IV), needles, $[M]^{15}_{5461}$ −50.4° (*c* 1.607 in H_2O). At room temp. no appreciable racemization of IV was observed in aq. or dil. MeOH soln. during 24 hrs. but at 56° a 2% aq. soln. lost 30% of its optical activity in 20 hrs. and when boiled it lost 10% in about 8 min. Although the iodide yields an optically active IV, its soln. in MeOH is optically inactive, presumably on account of optical racemization; however, when a small quantity of KI is added to IV in H_2O or dil. MeOH no detectable racemization occurs in 2 days at 15°. The mother liquor from III was converted into *d*-II *l-diacetyltartrate dihydrate*, $[M]^{15}_{5461}$ 110° (H_2O *c* 1.941); *d*-II *nitrate*, $[M]^{15}_{5461}$ 50.5° (H_2O, *c* 1.605). Decompn. of 0.96 g. II in 100 cc. H_2O with 2 cc. concd. HCl at 50° (1 hr.) gives IA, m. 119°; this is regarded as evidence that the IA in III and IV is indeed the meso base, since it is hardly possible that the meso base suffers a change of configuration into the *dl*- form on coördination and is then changed back quant. into the meso form under the conditions of decompn. *dl*-Stilbenediamine (V) yields a *diacetate monohydrate*, m. 131–2°. V was resolved through the H *d*-tartrate; *l*-V is stable on heating at 100° for 16 hrs. I and *l*-V give *isobutylenediamino-l-stilbenediaminopalladous iodide hydrate*, pale-yellow needles; the *nitrate*, needles, is less sol. in H_2O than is *d*-II nitrate; $[M]^{15}_{5461}$ −497°, $[M]^{15}_{5461}$ −624° (H_2O, *c* 1.0028); decompn. of the iodide with dil. HCl gives *l*-V. In these salts the 2 Ph groups are in the cis relationship and the possibility of their resolution shows that in this cation the 4 valencies of the Pd atom cannot have the regular tetrahedral arrangement and hence presumably lie in 1 plane.

Organic syntheses with sulfuryl chloride. W. W. Binkley and Ed. F. Degering. *J. Am. Chem. Soc.* **61**, 3250–1(1939).—Addn. of 1/3 mole of amine to 0.5 mole of SO_2Cl_2 with cooling, followed by gentle refluxing for 24 hrs., gives *dialkylaminesulfuryl chlorides: di-Me*, b_{10} 66°, d^{25}_4 1.337, n^{20} 1.4526 (these temps. for d. and *n* for other compds.); *di-Et* (I), b_6 69°, d. 1.221, *n* 1.4564; *di-Pr*, b_4 83.5°, d. 1.195, *n* 1.4615; *di-Bu*, b_3 95–6°, d. 1.142, *n* 1.4648; these compds. have an irritating effect on the skin and the di-Me deriv. is also a lachrymator. Esters of *N,N*-dialkylaminesulfonic acids are obtained from the metathesis of I and the proper Na alkoxide and in small yields from Et_2NH and the appropriate ester of $ClSO_3H$; *diethylaminesulfonates:* Et, b_5 86°, d. 1.076, *n* 1.4307; *Pr*, b_3 80.5°, d. 1.068, *n* 1.4331; *Bu*, $b_{2.25}$ 73.5°, d. 1.046, *n* 1.4352; these are pleasant-smelling liquids. The Me esters of the *N,N*-dialkylaminesulfonic acids were prepd. by the action of $ClSO_3Me$ on $R_2NH.HCl$ or by the alcoholysis of the chlorides with MeOH; *Me N,N-diethylaminesulfonate*, m. 80°; *Pr analog*, m. 135°; *Bu analog*, m. 117°.
C. J. West

Method for the preparation of α,β-diglycerides of fatty acids. B. F. Daubert and C. G. King. *J. Am. Chem. Soc.* **61**, 3328–30(1939).—3-Mono-Na glyceroxide (Fairbourne and Toms, *C. A.* **15**, 3079) in dry C_6H_6 and $PhCH_2OCOCl$, allowed to stand 24 hrs. at room temp. and then heated gently, give 83% of *3-carbobenzyloxyglycerol* (I), pale-yellow oil. I in C_6H_6-quinoline and palmitoyl chloride, shaken for 2 hrs. and then allowed to stand at room temp. for 4 days, give 80% of *3-carbobenzyloxy-1,2-dipalmitin*, m. 71°; catalytic reduction (Pd black) in abs. EtOH is complete in about 2 hrs. at room temp. and 2 atm. pressure and gives 76% of *1,2-dipalmitin* (II), m. 64°; the same II resulted by catalytic reduction of the α′-tritYl deriv. at 45–50° under 3 atm. pressure. *3-Carbobenzyloxy-1,2-dimyristin*, m. 67–8°; *1,2-dimyristin*, m. 80° (59%). *3-Carbobenzyloxy-1,2-glycerol dibenzoate*, on reduction, gives 70% of glyceryl 1,2-dibenzoate (III), m. 58°; *1-p-bromobenzoyl deriv.*, m. 107°. When II is allowed to stand 24 hrs. in soln. in 0.1, 0.05 and 0.025 *N* EtOH-HCl or EtOH-NH_3 there is a marked drop in m. p. in the recovered product but there is no change in that of III. Soly. in EtOH (g. per 100 ml.) at 25°: α- and β-monopalmitin 4.09, 4.61; β-*p*-bromobenzoyl-α,α′-benzylideneglycerol in EtOH and Et_2O at 26° 0.50, 1.15; β-palmitoyl-α,α′-benzylideneglycerol in EtOH and Et_2O at 26° 1.75, 17.40.

Preparation of tricaprylin. E. B. Hershberg. *J. Am. Chem. Soc.* **61**, 3587–8(1939).—Details are given of the prepn. of tricaprylin (b_1 233–3.5° (cor.), m. 9.8–10.1°) in 89% (based on I) or 84% yield (based on II) by the reaction of 73.5 g. of $C_3H_5(OH)_3$ (I) in 25–50 cc. H_2O, 410 g. octanoyl chloride (II) and 181 g. of 85% KOH in 375 cc. H_2O (simultaneous addn. during 1 hr.) at −5 to 0°, with 3 hrs. addnl. stirring at −10 to −5°; the product is extd. with Et_2O and distd.
C. J. West

Pyrolysis of diglycolic anhydride. Charles D. Hurd and Howard G. Glass. *J. Am. Chem. Soc.* **61**, 3490–1 (1939).—Diglycolic anhydride (I) undergoes pyrolysis at 450–500° into maleic anhydride (II); the yield varies from 44 to 71%; this reaction involves lengthening of the C chain. Concurrently, a small yield of ketene is obtained. The sepn. of I and II is accomplished by the selective solvent action of C_6H_6; both are sol. in hot C_6H_6 whereas I seps. on cooling the soln. to 6°; after concg. the filtrate and cooling till crystals of I no longer appear, furan is added, pptg. II; the recovery of I is almost quant., that of II is 89–95%.
C. J. West

Ricinus communis. I. Oxidation of ricinoleic acid. St. Elmo Brady. *J. Am. Chem. Soc.* **61**, 3464–7(1939).—The prepn. and purification of ricinoleic acid (I), its Et ester (II), b_{1-2} 193–4°, n^{25}_D 1.4595, d^{20}_0 0.9182, and the acetate of II, b_{2-3} 196°, n^{25}_D 1.452, are described. Oxidation of 50 g. II in 350 cc. Me_2CO with 200 g. $KMnO_4$ (added during 1 hr. with gentle refluxing of the soln.) gives 7.1 g. of neutral products and 40.7 g. of acidic products; the 17.1 g. of liquid acids consist of caproic, heptylic and caprylic acids; the 22 g. of solid acids consist of azelaic, suberic and β-hydroxypelargonic acids, with an acid, m. 96°, which was not identified. Oxidation of 5 g. of I with alk. $KMnO_4$ at 0° gives 1.8 g. of the trihydroxystearic acid m. 141° (III) and 1.7 g. of the acid m. 110° (IV), with 1.5 g. of an oily product. Ricinelaidic acid gives IV with only a small quantity of III. Oxidation of both III and IV with HIO_4 gives β-hydroxypelargonic aldehyde and aldehydoazelaic acid. Aldehydoöctanoic acid with acid $KMnO_4$ gives azelaic acid.
C. J. West

Carbamates and α-amino acid esters and their polycondensation. Max Frankel, Otto Neufeld and Ephraim Katchalski. *Nature* **144**, 832–3(1939); cf. *C. A.* **33**, 9285².—The Et carbamates of glycine (I), alanine (II) and phenylglycine have been prepd. by the passage of CO_2 through the corresponding α-amino acid ester or its soln. At room temp. the compds. decomp. readily, giving off CO_2. This class of compds. is invaluable for carrying out polycondensations. On standing for several weeks I yields a glycine peptide of high chain length and II yields a product giving the biuret reaction.
Rachel Brown

Hydrogenation of 1,3-diketones to ketols. Paul S. Stutsman and Homer Adkins. *J. Am. Chem. Soc.* **61**, 3303–6(1939).—Sprague and A. (*C. A.* **29**, 734⁸) obtained the ketol $Me_3CCOCH_2CH(OH)Me$ in 68% yield by hydrogenation of Me_3CCOCH_2Ac. A study is now reported of conditions under which other ketols, less resistant to hydrogenation, could be obtained by the partial hydrogenation of the corresponding 1,3-diketones. Hydrogenation at 100° over Raney Ni of the diketones in MeOH gave in general the highest yields of ketols ($RCOCH_2CH(OH)Me$); these yields (%) were (R given): Me 35, Et 51, Pr 58, iso-Pr 50, Bu 66, iso-Bu 49, *sec*-Bu 64. Other solvents gave in several cases lower yields, though the differences between solvents was in general negligible; for R = *tert*-Bu the yields in MeOH, Et_2O and EtOH were 66, 68 and 70%. In order to obtain the above yields the shaking of the reaction vessel was stopped after 0.9–1 mole of H per mole of diketone had been adsorbed. The following method gives better results: 1 mole of H per mole of diketone was added to the diketone, MeOH and catalyst in the reaction vessel contg. N at a pressure of about 100 atm.; the mixt. was shaken at 100° until the pressure was const.; the method requires about 110 min. due to the low pressure of H as compared with about 20

min. under 125 atm. H; in the case of R = Me, iso-Bu and *sec*-Bu the yields were raised by 4, 20 and 17%, resp. H did not react at the CO next to R until the CO next to the Me group had been hydrogenated. The hydrogenation of 1,3-diketones may be continued beyond the ketol stage to give good yields of glycols, $RCH(OH)CH_2CH(OH)Me$; the yields of R = Me, Pr, Bu and *sec*-Bu are 92, 94, 94 and 80%, resp.; these hydrogenations were made at 100–25° in 1.5–3 hrs. at 100 atm. H with 4 g. Raney Ni. Evidence is presented that the cleavage of diketones previously reported is really a hydrogenolysis and not a disproportionation of a ketol subsequent to hydrogenation; heating *tert*-$BuCOCH_2CH(OH)Me$ in Et_2O with Raney Ni at 60° for 12 hrs. causes no change; hydrogenation of BzCHEt-Ac caused 27% cleavage. *Hexan-3-on-5-ol*, b_{12} 75 8°, *n* 1.4280, d. 0.950 (n_D^{25} and d_4^{25} throughout); pentan-2-on-4-ol, b_{43} 93–5°, *n* 1.4238; *heptan-4-on-2-ol*, b_{24} 101° *n* 1.4300, d. 0.930; *2-methylhexan-3-on-5-ol*, b_9 72–3°, *n* 1.4278, d. 0.929; *octan-4-on-2-ol*, b_8 91°, *n* 1.4333, d_4 0.920; *6-methylheptan-4-on-2-ol*, b_9 86°, *n* 1.4294, d. 0.914 (*phenylhydrazone*, m. 111–13°); 2,2-dimethylhexan-3-on-5-ol, b_{10} 72–4°, *n* 1.4243; *5-methylheptan-4-on-2-ol*, b_{36} 113–14°, *n* 1.4318, d. 0.921; 4-hexen-3-one, b_{740} 136–9°, *n* 1.4345, d. 0.851 (*2,4-dinitrophenylhydrazone*, red, m. 164–5°); *2-methyl-4-hexen-3-one*, b_{739} 117–8.5°, *n* 1.4345, d. 0.843 (*2,4-dinitrophenylhydrazone*, orange, m. 140–1°); 2-hepten-4-one, b_{740} 156–62°, *n* 1.4383, d. 0.852 (*2,4-dinitrophenylhydrazone*, red, m. 112 3°); *2-octen-4-one*, b_{740} 178°, *n* 1.4393, d. 0.852 (*2,4-nitrophenylhydrazone*, orange, m. 108–9°); *6-methyl-2-hepten-4-one*, b_{711} 168 70°, *n* 1.4388, d. 0.841 (*2,4-dinitrophenylhydrazone*, red, m. 101–1.5°); *5-methyl-2-hepten-4-one*, b_{710} 170°, *n* 1.4400, d. 0.848; *3-methylheptan-4-one*, b_{740} 152–4°, *n* 1.4103, d. 0.817 (*semicarbazone*, m. 106 7°); 2,2-dimethyl-4-hexen-3-one, b_{740} 152 3°, *n* 1.4380, d. 0.843 (*2,4-dinitrophenylhydrazone*, yellow, m. 135 5.5°); *heptane-2,4-diol*, b_8 107–8°, *n* 1.4386, d. 0.926 (*bisphenylurethan*, m. 101–1.5°); *octane-2,4-diol*, b_8 117–18°, *n* 1.4422, d. 0.918 (*bisphenylurethan*, m. 126 7°); *5-methylheptane-2,4-diol*, b_8 111–12°, *n* 1.4449, d. 0.928 (*bisphenylurethan*, m. 129–30°); 5-methylhexane-2,4-diol bisphenylurethan, m 134–5°; *6-methylheptane-2,4-diol bisphenylurethan*, m. 143–3.5°. C. J. West

The molecular structures of glyoxal and dimethylglyoxal by the electron diffraction method. James E. LuValle and Verner Schomaker. *J. Am. Chem. Soc.* **61**, 3520–5 (1939).—The configurations are given by the following parameters: Glyoxal: C—H = 1.09 A. (assumed, C···O = 1.20 ± 0.01 A., C—C = 1.47 ± 0.02 A., angle C—C···O = 123° ± 2°. Dimethylglyoxal: C—H = 1.09 A. (assumed), C=O = 1.20 ± 0.02 A., C_2···C_3 = 1.17 ± 0.02 A., C_1···C_2 = 1.54 ± 0.02 A., angle CO···C=O = 1.23° ± 2°, angle CH_3—C=O = 122.5° ± 1°. The electron diffraction data and the dipole moment data, as well as chem. information, indicate uniformly that both mols. are coplanar with the trans configuration and that rotation around the C—C bond connecting the adjacent carbonyl groups is restricted. A. B. Garrett

Action of diazonium salts on ascorbic acid; a general reaction of dienols. Rudolf Weidenhagen, Hans Wegner, K. H. Lung and L. Nordström. *Ber.* **72B**, 2010–20 (1939).—A characteristic property of ascorbic acid (I) is its strong reducing action by virtue of the conversion of the dienol to a diketo grouping, with formation of dehydroascorbic acid (II). In a study of the action of diazonium salts on I a different course of the reaction was found. When, e. g., 10% aq. solns. of $(MeC_6H_4N_2)_2SO_4$ and I are mixed in equimol. proportions there seps. in a few min. a cryst. substance (III) which soon fills the whole soln. III is *l-threonolactone p-tolylhydrazidooxalate*, CO.O·CH_2.CH(OH).CHOCOCONHNHC$_6$H$_4$Me. Its formation is explained as follows: I is oxidized as usual to II and the diazonium salt is reduced to $MeC_6H_4N{:}NH$. The free CO groups of II add water; the $MeC_6H_4N{:}NH$ is reactive enough to abstract H from the resulting dihydrate, the dehydrogenation being accompanied by rupture of the 2,3-union to give the oxalate, $HO_2CCO_2CH(CO_2H)CH(OH)CH_2OH$ (IV), of *l*-threonic acid (V) and reduction of the diimine to the hydrazine which with IV gives the hydrazide; the latter is at the same time lactonized to III. III, obtained nearly quantitatively, can be recrystd. unchanged from AcOEt-petr. ether, AcOH and abs. alc., but on short boiling with water it is hydrolyzed to V and *oxalic mono-p-tolylhydrazide*, $HO_2CCONHC_6H_4Me$ (VI), m. 153° (foaming); on longer boiling, $HO_2CCO_2H{\cdot}NH_2C_6H_4Me$ is formed. The cleavage of III can also be effected in alc. with $PhNHNH_2$, which gives the mixed *hydrazide*, $PhNHNHCOCONHNHC_6H_4Me$, m. 252–3° (foaming). Erlbach (*C. A.* **29**, 3652[4]) obtained the corresponding products from PhN_2Cl and isoascorbic acid but gave an entirely different interpretation of the reaction. The reaction is distinctly diphasic: (1) very rapid disappearance of the diazonium compd. and I; (2) cleavage of the II, a pronounced time reaction depending on the reactivity of the diazonium compd. This characteristic reaction with diazonium compds. is applicable to all compds. of dienol character, such as 3,4-dihydroxytetrone (VII) (Micheel, *et al.*, *C. A.* **32**, 113[5]), reductic acid (VIII), and the open-chain reductone (IX). The open-chain dihydroxymaleic acid with $(2,5\text{-}Cl_2C_6H_3N_2)_2SO_4$ gave, with dehydrogenation and cleavage of 1 mol. CO_2, a C_3-compd. which reacted further with the arylhydrazine simultaneously formed, but because of the instability of the intermediate diketotartaric acid, the reaction was not entirely homogeneous and its interpretation is reserved for a later report. This is also true of pyrocatechol. III (77% yield), m. 175–6° (foaming) (these unstable compds. give a correct m. p. only when placed in a bath preheated to a temp about 10° below the m. p.), $[\alpha]_D^{25}$ 59.1° (*c* 0.533, alc.) V, obtained, mixed with the lactone, as a brownish sirup, was identified as the phenylhydrazide, m. 158°, $[\alpha]_D^{25}$ 57.2° (*c* 0.533, alc.), and the *dibenzoyl lactone*, m. 114°, $[\alpha]_D^{25}$ 171.4° (*c* 0.533, alc.). *Ph homolog* of III (91.7% from I and PhN_2Cl), faintly yellowish, m. 155–7° (foaming), $[\alpha]_D^{25}$ 63.8° (*c* 0.533, alc.). *2,5-Dichlorophenyl analog* (86%), yellowish, m. 110° (foaming), $[\alpha]_D^{25}$ 84.8° (*c* 0.533, alc.). *d-Erythrono isomer* of I (38.1% from isoascorbic acid), druses of leaflets, m. 175° (foaming), from AcOEt-petr. ether, leaflets, m. 177° (foaming), from abs. alc., $[\alpha]_D^{25}$ −73.2° (*c* 0.533, alc.), gives on hydrolysis VI and *d*-erythronolactone, m. 104–5°, $[\alpha]_D^{25}$ −73.2° (*c* 0.533, water). *p-Tolylhydrazidooxalylglycolic acid* (100% yield from VII), m. 184 5° (foaming). *2-Ketoglutaric mono-p-tolylhydrazide*, $HO_2CCH_2CH_2COCONHNHC_6H_4Me$ (40% from VIII), faintly yellowish, m. 157° (decompn.), titrates as a monobasic acid and forms a *semicarbazone*, faintly yellowish, m. 207° (decompn.). IX with diazotized 2,4-$Cl_2C_6H_3NH_2$ gives HCO_2H and *glyoxylic 2,5-dichlorophenylhydrazide hydrate*, $(HO)_2CHCONHNHC_6H_3Cl_2$, m. 125–6°, which shows the characteristic reactions of glyoxal derivs. and forms a *phenylhydrazone*, faintly yellowish, m. 223° (gas evolution). C. A. R.

Condensation brought about by bases. VII. The acylation of ethyl isobutyrylisobutyrate and the cyclization of a 3,5-diketo ester by means of sodium triphenylmethyl. Boyd E. Hudson, Jr., and Charles R. Hauser. *J. Am. Chem. Soc.* **61**, 3567–70(1939); cf. *C. A.* **33**, 4220[1].—Et isobutyrylisobutyrate (I) (prepn. from the enolate of Et isobutyrate (II) and isobutyryl chloride (III) (55%) and from Et α-bromoisobutyrate and Mg (72%) given) with Ph_3CNa is converted into its Na enolate, which reacts with III to give 46% of *Et 2,2,4,4,6-pentamethyl-3,5-diketoheptanoate* (IV), $Me_2CHCOCMe_2COCMe_2CO_2Et$, b_{15} 137–8°. With Ph_3CNa in Et_2O IV is cyclized in 3 days to hexamethylphloroglucinol, m. 79–80° (30% yield). II and Ph_3CNa in Et_2O, allowed to stand 24 hrs. and poured into III in Et_2O, give 42% of IV; since I does not condense with III this result shows that I produced by the self-condensation of II by Ph_3CNa is in the form of its Na enolate. Cleavage of IV with EtONa gives 74% of II. The enolate of I and AcCl give 52% of *Et 2,2,4,4-tetramethyl-3,5-diketohexanoate*, b_{15} 122–4°; this could not

be cyclized with EtONa or Ph_3CNa, an alkali-insol. oil resulting in each case. C. J. West

Isotopic exchange reaction between deuterium oxide and *cis*- and *trans*-glutaconic acids. E. M. Evans, H. N. Rydon and H. V. A. Briscoe. *J. Chem. Soc.* **1939**, 1673–9.—The exchange reactions between *cis*- and *trans*-glutaconic acids and D_2O in the presence of an excess of alkali have been studied. The results clearly show that 3 H atoms are concerned, a result in accordance with modern views on tautomerism. In the exchange reactions between the trans ion and 10% D_2O, using 5 mols.-% excess of NaOH in *N* soln. at 20°, by plotting percentage interchange against time, the data represent a pseudo-unimol. reaction with a velocity const. of 22.5×10^{-4} min.$^{-1}$; after the NaOH soln. had stood in a glass container for several months, the const. had fallen to 12.4. The time of half-interchange is 5 hrs. Comparison of this value with the results of other workers shows that the glutaconate ion is an acid, in the Brönsted sense, of the same order of strength as Me_2CO and with a mobility greater than that of most tautomeric systems which have been investigated under like conditions. The high mobility leaves no doubt that the tautomerism exhibited by glutaconic acid is of the "bimol." class, i. e., the proton and the anion have free independent existence. The results with the cis acid shows that, at equil., the interchange was identical with that found for the trans acid; the same 3 H thus take part in the exchange. In 1 hr. at 20° the exchange with the cis acid was 4 times that for the trans acid under the same conditions; this confirms the real difference between the 2 isomers. This greater mobility with the cis acid is no doubt due to the instability and higher energy content of the cis ion; steric inversion to the trans ion will bring about exchange of 1 H. The results show that this inversion must be a faster process than the isomerization process; this seems to be unlikely if the mechanism of steric inversion involves the mesomeric ion. It is suggested that ionization of H of the CH_2 group is responsible and that this occurs through the agency of H-bond formation which is sterically possible only in the case of the cis acid. The exchange reaction with glutaric acid was also studied in order to establish that CH_2 groups exchanged only slowly even when present in a mole contg. 2 activating groups such as CO_2H. C. J. West

Constitution of arabic acid. II. Degraded arabic acid. F. Smith. *J. Chem. Soc.* **1939**, 1724–38; cf. *C. A.* **33**, 6253[1].—The Ba salt of degraded arabic acid prepd. from the acid by hydrolysis with 0.01 *N* H_2SO_4 is identical with that obtained by autohydrolysis; it has $[\alpha]_D$ −9° (H_2O, *c* 1), equiv. 670 (from Ba content); the free acid (I) has $[\alpha]_D^{15}$ −9° (H_2O, *c* 1), equiv. 660 (titration), I no. about 10; fractional pptn. of I or the Ba salt shows that they are essentially homogeneous. Since I contains only galactose (II) and glucuronic acid (IIA) residues, the equiv. figures indicate the presence of a repeating unit composed of 1 IIA and 3 II units. Both I and the Ba salt reduce Fehling soln. and it would seem that this portion of the arabic acid mole is of finite size and relatively small in comparison with the parent acid and with highly complex saccharides, such as starch and cellulose. Methylation of I with Me_2SO_4 and NaOH gives a product with a free CO_2H group which, on esterification and further treatment with Purdie's reagents, gives a fully methylated I, pale yellow, $[\alpha]_D^{15}$ −54° ($CHCl_3$, *c* 1); fractional pptn. failed to disclose the presence of degraded material. Hydrolysis of the Me ester with 6.5% MeOH-HCl (boiling 10 hrs.) gives a nonreducing sirup which was heated with 0.15 *N* $Ba(OH)_2$ for 2 hrs. at 55°, giving a sirup and a Ba salt; from the values of *n* of various fractions it is calcd. that the sirup contains 1.84 g. (1 mole) of 2,3,4,6-tetramethylmethylgalactoside (III), 8.63 g. of the 2,3,4-tri-Me deriv. (IV) (5 moles) and 4.8 g. of the 2,4-di-Me deriv. (V) (3 moles), and the Ba salt (7.5 g.) is that of 2,3,4-trimethylmethylglucuronoside (VI) (3 moles); the amt. of III is 8.4% of the sirup. VI has $[\alpha]_D^{15}$ 80° (H_2O, *c* 0.9), and does not reduce Fehling soln.; there is no increase in MeO content when the Ba salt is remethylated. The free acid from VI boiled for 8 hrs. with 3% MeOH-HCl gives the Me ester of 2,3,4-trimethylmethylglucuronoside, $b_{0.02}$ 120° (bath temp.), n_D^{15} 1.4470, $[\alpha]_D^{15}$ 87° (H_2O, *c* 1); MeOH-NH_3 gives the *amide*, m. 183°, $[\alpha]_D^{15}$ 137.5° (H_2O, *c* 0.7). Methylation of glucuronolactone and esterification with 3% MeOH-HCl gives 2,3,4-trimethyl-α-methylglucuronoside (VII), $b_{0.2}$ 125°, n_D^{15} 1.4467, $[\alpha]_D^{15}$ 81° (H_2O, *c* 0.8); amide, m. 183°, $[\alpha]_D^{15}$ 138° (H_2O, *c* 0.6); these are identical with those from VI. The β-isomer of VII, esterified with CH_2N_2 gives an *amide*, m. 193°, $[\alpha]_D^{15}$ −47° (H_2O, *c* 1.2). The free acid from VI on oxidation with Br gives 2,3,4-trimethylsaccharolactone, whose *Me ester* (VIII) m. 107°, $[\alpha]_D^{15}$ 32° (equil. value in H_2O), $[\alpha]_D^{15}$ 102° (initial in MeOH, *c* 1) changing to 52° (equil. value). Oxidation of VIII with HNO_3 (1.5 hrs. at 50° and 3 hrs. at 95°) gives *dl*-xylotrimethoxyglutaric acid (IX) and *l*(+)-threodimethoxysuccinic acid (X), characterized as the amides. β-1,6-Anhydroglucopyranose, methylated and oxidized with HNO_3, gives VIII, IX and X. III is identified by converting it into the corresponding reducing sugar and its anilide, m. 192°. IV was transformed into 2,3,4-trimethylgalactose (XI), which gives a monohydrate, m. 80°, $[\alpha]_D^{15}$ 152° (H_2O, *c* 1) changing to 114°, and an *anilide*, m. 167° (cf. McCreath and Smith, *C. A.* **33**, 4202[2]). Oxidation of XI gives 2,3,4-trimethyl-δ-galactonolactone, $b_{0.09}$ 140–50°, n_D^{15} 1.4757, $[\alpha]_D^{15}$ 134° (after 10 min.) changing to 24° (after 9 hrs., H_2O, *c* 1); $PhNHNH_2$ gives the phenylhydrazide of 2,3,4-trimethylgalactonic acid, m. 175–6°; the *anilide* of the acid m. 165°, $[\alpha]_D^{15}$ 32° (H_2O, *c* 2.1). Oxidation of IV with HNO_3 (1 hr. at 50° and 2 hrs. at 80°) gives 2,3,4-trimethylmucic acid (Me ester, m. 102–3°; *diamide*, m. 273° (decompn.); *1-monoamide*, m. 156°, $[\alpha]_D^{15}$ 34° (H_2O, *c* 3); *bismethylamide*, m. 205°, $[\alpha]_D^{15}$ 7.5° (H_2O, *c* 1.3)); thus the Me groups in IV are in positions 2, 3 and 4. IV was synthesized as follows: α-methylgalactopyranoside and Ph_3CCl in C_5H_5N give the *6-trityl deriv.*, pale yellow, glassy residue, $[\alpha]_D^{15}$ 30° (Me_2CO, *c* 2); Me_2SO_4 and NaOH give the *2,3,4-tri-Me deriv.*, $[\alpha]_D^{15}$ 44° ($CHCl_3$, *c* 2); the 6-trityl group was removed by satg. an Et_2O soln. with HCl at 10°, giving IV. V exists in 2 forms. 2,4-Dimethyl-β-methylgalactoside, m. 165–6°, which is non-reducing; methylation gives the 2,3,4,6-tetra-Me deriv., m. 48°; *2,4-dimethylgalactose* (XII), as the monohydrate, m. 103°, $[\alpha]_D^{15}$ 122° (10 min.) changing to 85.6° (equil. value in H_2O, *c* 1.7). The α-isomer m. 105°, $[\alpha]_D^{15}$ 142° (H_2O, *c* 1.1); hydrolysis gives XII. XII forms an *anilide*, m. 216°. XII and $PhNHNH_2$, heated in dil. AcOH for 3 hrs. at 80°, give *4-methylgalactose phenylosazone*, m. 150°; in 3 years the m. p. falls to 130°; on crystn. from aq. MeOH a product, m. 158° (decompn.), results which is probably *4-methylanhydrogalactose phenylosazone*. XII and Br in H_2O at 20° (2 days) give a sirupy 2,4-dimethylgalactonolactone, $[\alpha]_D^{15}$ 100° (initial, in H_2O, *c* 1.2) changing to 62° in 18 hrs.; *phenylhydrazide*, m. 183°; heating the latter with 0.1 *N* H_2SO_4 gives *2,4-dimethyl-δ-galactonolactone*, m. 113°, $[\alpha]_D^{15}$ 162.2° (H_2O, *c* 0.54) changing to 52.6° in 20 hrs.; *2,4-dimethylgalactonamide*, m. 167°, $[\alpha]_D^{15}$ 59° (H_2O, *c* 0.8). Heating XII with HNO_3 for 24 hrs. at 50–5° and esterification give *Me 2,4-dimethyl mucic 3,6-lactone* (XIII), $b_{0.12}$ 190° (bath temp.), m. 111°, $[\alpha]_D^{15}$ 120° (H_2O, *c* 1), changing to 83.5° in 14 days (mutarotation still incomplete); *2,4-dimethylmucic diamide*, m. 229° (decompn.), $[\alpha]_D$ 30° (H_2O, *c* 1); *bismethylamide*, m. 214°, $[\alpha]_D^{15}$ 27° (H_2O, *c* 1.5). Methylation of XIII with Purdie's reagents and crystn. from Et_2O give Me 2,3,4,5-tetramethylmucate and from the mother liquor on addn. of petr. ether the *Me ester lactone* of *2,4,5-trimethylmucic acid*, m. 63–4°, $[\alpha]_D^{15}$ 85° (H_2O, *c* 1.2); *2,4,5-trimethylmucic diamide*, m. 225° (decompn.); *bismethylamide*, m. 232° (decompn.), $[\alpha]_D^{15}$ 23° (H_2O, *c* 1.3). A structure composed of the 12 units mentioned above joined by glucosidic links and having a single free reducing group protected with a Me residue would have a mol. wt. of 2494 and an equiv. of 831 (found by titration, 830) and a Me ester would have a MeO content of 46.4% (found, 45.2). The unmethylated degraded arabic acid calcd. on this basis would have a mol. wt. of 2003 (found by I no., 2000) and an equiv. wt. of 663 (found by direct titration, 660, and

from Ba content, 670). The degraded arabic acid reduces Fehling soln. and on the above data the mol. of min. size would consist of 12 units, 9 being *d*-galactose and 3 *d*-glucuronic acid. The mode of attachment of these units is indicated by the isolation of their various methylated derivs. The isolation of 1 mol. proportion of III and 3 of VI shows clearly that there must be 4 "ends" in the structure of the repeating unit of 12 sugar residues. The constitution can therefore be represented by a terminated chain of galactose residues to which are attached 3 side chains, each terminated by a glucuronic acid unit; the side chains may be attached to any but the terminal galactose units which furnish the III, the point of linking being indicated by the isolation of V. The view is supported by the isolation of equal amts. of VI and V. The evidence suggests that the galactose residues in the main chains are mutually joined by 1,6-glucosidic links or by 1,3-links or even by 1,6- and 1,3-links. The side chains each contg. a terminal glucuronic acid residue may be attached by 1,3-links or by 1,6-links and at this stage the possibility that they are joined by 1,3- and 1,6-links cannot be excluded. Structural formulas illustrating these possibilities are given. C. J. West

2-Alkylthiosemicarbazides. Eugène Cattelain. *Compt. rend.* **209**, 799–801(1939). As 2-alkylsemicarbazides, $NH_2CONRNH_2$, are obtained by the action of KCNO on an alkylhydrazine (I), so the corresponding 2-alkylthiosemicarbazides, $NH_2CSNRNH_2$, (II), are obtained by treating I in a similar fashion with KCNS, the first product being the thiocyanate, $NHRNH_2.SCNH$ (III), which on heating to a temp. varying with R isomerizes to II, which is purified by recrystn. from hot H_2O in which it is much more sol. than in cold. With aldehydes or ketones it readily forms 2-alkylthiosemicarbazones. The following were prepd.; II, R = Me, m. 183–4°, R = benzyl, m. 155°; III, R = Me and Et, both liquids, isomerizing to II at 165° and 140°, resp.; also 2-methyl- and 2-benzylthiosemicarbazones from benzaldehyde, m. 174° and 214.5°, resp., from anisaldehyde, m. 192° and 175°, and from *p*-methoxyhydratropaldehyde, m. 100° and 195°.
C. A. Silberrad

5-(*α-sec*-Butoxy)ethyl-5-alkylhydantoins. Robert J. Speer and Henry R. Henze. *J. Am. Chem. Soc.* **61**, 3376–7(1939).—One part of *α-sec*-butoxyethyl alkyl ketone (*C. A.* **33**, 5360⁹) is mixed with a suspension of 1.25 parts of KCN and 3 parts of $(NH_4)_2CO_3$ in 7–8 vols. of 50% EtOH and warmed at 55–60° for 5–6 hrs., giving *5-(α-sec-butoxy)ethyl-5-alkylhydantoins;* they are purified by crystn. from 50–60% EtOH or from C_6H_6-petr. ether; *Me* m. 203–4°, 36%; *Et* m. 190°, 41%; *Pr* m. 205–6°, 24%; *iso-Pr* m. 196–7°, 22%; *Bu* m. 204 5°, 36%; *iso-Bu* m. 192°, 44%; *sec-Bu* m. 189–90°, 30%; *Am* m. 178°, 31%; *iso-Am* m. 177°, 40%. These compds. are potentially important as *soporifics* or *anticonvulsants*.
C. J. West

Constitution of purine nucleosides. IX. Crotonoside. Roderick Falconer, J. Masson Gulland and Leonard F. Story. *J. Chem. Soc.* **1939**, 1784–7; cf. *C. A.* **34**, 769⁹.—Crotonoside (I), m. 243–5° (decompn.), is isolated in 0.53-g. yield from 500 g. ground, unshelled croton seeds by extn. with hot H_2O at 80° (Cherbuliez and Bernhard, *C. A.* **26**, 2967, 5077). Deamination of I with $NaNO_2$ and dil. AcOH gives xanthosine (?) (II), $[\alpha]_D^{19}$ −51.2° (0.1 *N* NaOH, *c* 1.029). 2,6-Dichloro-9-methylpurine and 40 parts dry EtOH-NH_3, heated 3 hrs. at 85–90°, give *2-chloro-6-amino-9-methylpurine*, needles; heating with EtONa for 3 hrs. at 130° gives *6-amino-2-ethoxy-9-methylpurine*, microcryst.; PH_4I in HI (d. 1.95) at 30–40° and then heated to boiling gives 9-methylisoguanine (III). The 7-isomer of III could not be prepd. from 2,6-dichloro-7-methylpurine, 7-methylguanine resulting through an isomeric change. Comparisons of the ultraviolet absorption spectra of I, III and guanosine (IV) confirm that I is a 9-substituted deriv., that it is not identical with IV and that its aglucone is isoguanine. The spectrum of II is identical with that of authentic xanthosine. I is a 9-*d*-ribose deriv. of isoguanine. C. J. West

Oxidation of glycosides by means of lead tetraacetate in aqueous solution. J. M. Grosheintz. *J. Am. Chem. Soc.* **61**, 3379–81(1939); cf. *C. A.* **34**, 377⁸.—The oxidative cleavage of *α-* and *β*-Me-*l*-arabinopyranosides can be carried out quant. in aq. soln. with $Pb(OAc)_4$. Three moles of the oxidizing agent, instead of 2, are required to complete the reaction; the reason for this excess consumption of reagent is that in aq. soln. the 1 mole of HCO_2H formed during the 1st reaction is oxidized by 1 mole of $Pb(OAc)_4$ to 1 mole of CO_2. C. J. West

A method of preparing *β*-glucose. Willy Rasmussen. *Dansk Tids. Farm.* **13**, 273–9(1939)(English summary).—Ca bicarbonate is prepd. by suspending 0.7 g. $CaCO_3$ in a l. of distd. water and passing CO_2 until dissolved. To this soln. 100 g. of *α*-glucose is added and the soln. left for 24 hrs. at room temp. to permit mutarotation. The soln. is then filtered and heated to 40°, the excess CO_2 being forced out by agitation until a blue color is obtained with bromothymol (pH 7.4). A soln. of AcOH-free acetone is prepd. by shaking with $CaCO_3$, allowing to stand and filtering just before using. Equal vols. of the sugar soln. and the acetone are mixed and placed in a thermostat at 40°. In 5–10 min. 3 ml. of 0.2 *N* H_2SO_4 is added and the mixt. allowed to stand for 2 hrs. at 40°. At the end of this time active charcoal is added, the soln. is filtered and evapd. on a water bath or under a vacuum to a sirup which turns to a solid under frequent stirring. The solid is pulverized, dried at a temp. not above 60° or in a vacuum over H_2SO_4. The resulting product is claimed to be chiefly *β*-glucose. Otto Johnson

Synthesis of 5,6-dimethylglucose. M. R. Salmon and Garfield Powell. *J. Am. Chem. Soc.* **61**, 3507–10(1939) 1,2-Diacetoneglucose (I) and Na in Et_2O, allowed to react 2 days at room temp. and then treated with $PhCH_2OCH_2Cl$, give 55% of *3-benzyloxymethyldiacetoneglucose* (II), $b_{0.2}$ 163–77°; it forms a yellow, slightly viscous oil which did not crystallize. Reduction with Na in EtOH gives I. II also results in 4.5-g. yield from 10 g. 3-acetyldiacetoneglucose and 21 g. $PhCH_2OCH_2Cl$ in Et_2O with 85 g. powd. KOH (added during 1 hr. and refluxed 1.5 hrs.). II (96 g.) in 300 cc. glacial AcOH and 30 cc. H_2O, allowed to stand 14 hrs. at room temp., the solvent removed *in vacuo*, the residue taken up in 300 cc. AcOH and 50 cc. H_2O, allowed to stand 9 hrs. at room temp., the solvent removed *in vacuo*, the aq. soln. neutralized with Na_2CO_3 and extd. with $CHCl_3$, gives 1.23 g. of *3-benzyloxymethylacetoneglucose* (III), an oil; PhNCO gives the *5,6-dicarbanilyl deriv.*, m. 148–8.5°; this also results from II and PhNCO. Reduction of III with Na and EtOH gives 68% of acetoneglucose. III (86 g.) and Me_2SO_4 with NaOH, followed by 2 methylations with MeI and Ag_2O, give 49 g. of *5,6-dimethyl-3-benzyloxymethylacetoneglucose* (IV), $b_{0.12}$ 155–63°. Reduction of IV with Na in EtOH gives 71% of *5,6-dimethylacetoneglucose* (V), $b_{0.15}$ 105–10°, m. 56–6.5°, $[\alpha]_D^{19}$ −12.8° (H_2O, *c* 4.18); PhNCO in C_6H_6 at 85° (3 hrs.) gives the *3-carbanilyl deriv.*, m. 88–9°, $[\alpha]_D^{19}$ −62.3° (EtOH, *c* 3.25); with C_5H_5N as catalyst there results a compd. m. 241–2°, corresponding to the *N,N'-diphenylallophanate* of V; decompn. of the carbanilyl compd. with MeONa gives V, the crystals of which were used for seeding the main fraction of V. V with *N* HCl at 80° for 30 min. gives *5,6-dimethylglucose* (VI), colorless or greenish yellow oil, which could not be crystd. VI reduces Fehling soln. and aq. $KMnO_4$ at room temp. and reddens fuchsin-SO_2 but the color does not develop as rapidly nor is it as deep as is typical of a true aldehyde. VI has $[\alpha]_D^{19}$ 4 ± 0.3° (H_2O, *c* 2.4) and does not show mutarotation. The osazone is an oil; *p-bromophenylosazone*, yellow, m. 155.5–6° (decompn.). Degradation of VI with HIO_4 gives dimethylglyceric acid (*p-phenylphenacyl ester*, m. 62.5–3°; *p-bromophenacyl ester*, m. 66.5–7.5°).
C. J. West

The oxidation of aldoses by hypoiodite. IV, V. Karl Myrbäck. *Svensk Kem. Tid.* **51**, 179–92, 206–17(1939) (in German); cf. *C. A.* **32**, 4472⁴; **33**, 3720⁴, 5773⁵, 8176⁵.—The study of the oxidation of aldoses by hypoiodite in various alk. solns. is continued to include maltose, cellobiose, lactose, melibiose, mannose, xylose, arabinose, ribose, lyxose, fucose and rhamnose. Aldoses are oxi-

dized to the corresponding acids. This may require a very long time and be incomplete. The alkali does not destroy the sugar. When conditions are right the reaction will be quant. For quant. detns. the sugar should not exceed 100 mg. and there should be a third more hypoiodite than calcd. After this add the alkali with a buret slowly over a period of 10 min. There should be 1.5 equivs. NaOH for each equiv. I. Let it stand for 15 min. and titrate with 0.1 *N* $Na_2S_2O_3$. A. R. Rose

Reaction of benzene with methylcyclobutene and methylenecyclobutane in the presence of sulfuric acid. V. N. Ipatieff and Herman Pines. *J. Am. Chem. Soc.* **61**, 3374–6(1939).—A mixt. of methylenecyclobutane and methylcyclobutene, b_{736} 40–2.5°, results in 65% yield by the action of Zn upon pentaerythrityl bromide. Addn. of 25 g. of this mixt. in 35 g. C_6H_6 to 30 g. 96% H_2SO_4 and 15 cc. C_6H_6 at 4° during 1 hr. gives 31.3 g. of acid layer and 93.5 g. of hydrocarbon layer; distn. showed that the latter contained 50 moles monomethylcyclobutylbenzene, 45 moles of the di-deriv. and 5 moles of the tri-deriv. *1-Methyl-1-phenylcyclobutane* (I), b_8 69°, b_{760} 208.6°, *dt/dp* (760–740 mm.) 0.05°/mm., $d^{20}_{vac.}$ 0.9192, $-dD/dp$ 0.00074, n^{19}_D 1.5132; *4-acetamino deriv.*, m. 144°; *2,4-diacetamino deriv.*, m. 202°. *1,4-Di(1'-methylcyclobutyl)benzene*, b_6 123–5°, m. 34°, $d^{20}_{vac.}$ 0.9344, n^{19}_D 1.5203; oxidation with HNO_3 gives terephthalic acid. Hydrogenation of I in pentane at 65° (Ni-kieselguhr catalyst) gives *1-methyl-1-ohexylcyclobutane*, b_9 72–3°, b_{760} 201–5°, *dt/dp* (752–739 mm.) 0.08°/mm., d^{20}_4 0.8595, n^{19}_D 1.4662; dehydrogenation over Pt-Al_2O_3 at 250° gives *tert*-AmPh and 2-phenylpentane. The cyclobutyl ring becomes very stable toward H_2SO_4 or nitrating mixt. when a Ph group is attached to it. C. J. West

Substituted ring compounds. I. Synthesis of α,α,γ-trimethylcyclopentanone. Muhammad Qudrat-i-Khuda and Subash Kumar Ghosh. *J. Indian Chem. Soc.* **16**, 287–95(1939).—Synthesis of α,α,γ-trimethylcyclopentanone (I) was effected from α,α,γ-trimethyladipic acid (II), prepd. by 2 independent processes from mesitonic ester III (*J. Chem. Soc.* **85**, 1219 (1904)). Mesityl oxide (98 g.) in boiling alc. was shaken with 131 g. KCN in 270 cc. H_2O and the cooled reaction mixt. was treated with 93 g. $FeSO_4$ in 180 cc. H_2O. Acidification of the reaction product with concd. HCl gave 55 g. of a mixt. of mesitonic acid and mesitylic acid. Esterification and fractional distn. gave 30 g. of III, b_{30} 115–6°, $d^{12.8}_4$ 0.96095, $n^{23.8}_D$ 1.41576, M. R. 44.9 (calcd. 45.3), and 18 g. of Et mesitylate, b_{35} 140–50°. Treatment of 25.8 g. III in 80 cc. of dry benzene with 4.3 g. Mg turnings and 25.1 g. $BrCH_2CO_2Et$ and decompn. of the product with dil. H_2SO_4 yielded 17 g. of *Et α,α,γ-trimethylbutyrolactone-γ-acetate* (IV), $C_{11}H_{18}O_4$, b_7 148–50°, $d^{21.2}_4$ 1.0471, $n^{23.2}_D$ 1.44355, M. R. 54.2 (calcd. 54.11), and 2 g. of viscous liquid, b_5 170–5°. IV (12 g.) was heated on the steam bath for 3 hrs. with 26 g. PCl_5 and the cooled clear soln. was poured into 75 cc. abs. alc. The mixt. was dild. with H_2O and extd. with Et_2O, giving 78% of *Et α,α,γ-trimethyl-γ-chloroadipate* (V), $C_{13}H_{23}ClO_4$, b_5 113–5°, $d^{21.5}_4$ 1.0381, $n^{23.8}_D$ 1.43913, M. R. 70.6 (calcd. 70.4). Reduction of 20 g. V by refluxing with 40 g. Zn dust in 290 cc. AcOH gave 8 g. of *Et α,α,γ-trimethyladipate* (VI), $C_{13}H_{24}O_4$, b_{16} 145–6°, d^{22}_4 0.99383, n^{23}_D 1.44335, M. R. 65.3 (calcd. 65.6), hydrolyzed by refluxing with 15% HCl for 12 hrs. to II, $C_9H_{16}O_4$, m. 80°. Condensation of 114.6 g. III with 75.4 g. $NCCH_2CO_2Et$ in the presence of 6 cc. piperidine and anhyd. Na_2SO_4 yielded 98 g. of *Et α-cyano-β,δ,δ-trimethylbutene-α,δ-dicarboxylate*, $C_{14}H_{21}NO_4$, b_4 162°, $d^{23.8}_4$ 1.0431, $n^{23.8}_D$ 1.45717, M. R. 69.68 (calcd. 69.4), reduced by Al-Hg in moist Et_2O to the corresponding *satd. compd.*, $C_{14}H_{23}NO_4$, b_8 155–6°, d^{22}_4 1.0230, n^{23}_D 1.44033, M. R. 69.4 (calcd. 69.6), hydrolyzed by refluxing with concd. HCl for 35 hrs. to II. A mixt. of 21.5 g. VI and 2.3 g. Na in 100 cc. alc. was refluxed for 6 hrs., cooled, decompd. with dil. HCl and extd. with ether, yielding 48.7% (8.5 g.) of *Et α,α,γ-trimethylcyclopentane-δ-carboxylate* (VII), $C_{11}H_{18}O_2$, b_5 88–90, $d^{21.8}_4$ 0.98559, $n^{23.8}_D$ 1.43882, M. R. 52.85 (calcd. 52.5). Refluxing with dil. HCl for 2 hrs., neutralizing with Na_2CO_3 and extg. with Et_2O gave 45.5% of the required ketone (I), $C_9H_{14}O$, b_{18} 65–6°, $d^{22.6}_4$ 0.87660, $n^{23.6}_D$ 1.42426, M. R. 36.68 (calcd. 36.9); *semicarbazone*, m. 173°; *monobenzylidene compd.*, m. 125–6°. Dibromodihydroisophorone (VIII) (25 g.) was shaken with 17 g. KOH in 667 cc. H_2O for 6 hrs. and the mixt. was acidified with HCl. Steam distn. gave a diketone (IX), m. 168–9° (89–90° according to Wallach, *C. A.* **13**, 427[1]), converted into trimethylhydroxycyclopentanecarboxylic acid, m. 90°, on heating in a sealed tube with 50 cc. KOH (1:2) at 140° for 4 hrs. Treatment of VIII with PbO_2 yielded I. The structures of I, VIII and IX are established and differ from those suggested by Wallach. C. R. A.

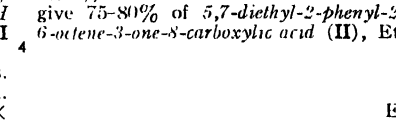
Some derivatives of cyclopentane. Robert B. Rothstein and Mario Rothstein. *Compt. rend.* **209**, 761–2 (1939); cf. *C. A.* **29**, 3308[1]; **30**, 1742[6].—Cyclopentene (I) is obtained practically pure and in theoretical yield by passing cyclopentanol in vapor form over a Fourneau porous catalyzer (*C. A.* **16**, 2495). 2-Chlorocyclopentanol (II) is thence prepd. in 60–70% yield by shaking in a closed vessel 90 g. chlorourea (in 12% soln.), 37.5 g. AcOH and 78 g. I until the amt. of HOCl in the residual H_2O is const. The product is extd. with Et_2O, washed and dried over Na_2SO_4. On fractionating *trans*-2-chlorocyclopentanol is obtained, the cis isomer distg. over with the dichlorocyclopentane formed at the same time. II b_{15} 81–2°, $d^{22.5}_4$ 1.1686, $n^{22.5}_D$ 1.4782. Epoxycyclopentane (III) is prepd. by agitating for some hrs. 77 g. II and 150 g. aq. NaOH (d. 1.332), H_2O is added to dissolve the NaCl, and III extd. with Et_2O, washed, dried and fractionated, III distg. over at 100–1°. It has d^{23}_4 0.9670, n^{19}_D 1.4321; yield 80–5%. From III there were prepd. in similar fashion as before the lactones $CH_2(CH_2)_3CHR$ / $CH_2.CH_2.CH.O.CO$ R = Et, b_{14} 128, $n^{19.5}_D$ 1.4672, $d^{19.5}_4$ 1.0504; Pr, b_{14} 141°, n^{23}_D 1.4660, d^{23}_4 1.0287; Bu, b_{16} 154°, $n^{18.5}_D$ 1.4682, $d^{18.5}_4$ 1.0119; iso-Bu, b_{15} 148°, n^{21}_D 1.4685, d^{21}_4 1.0098; iso-Am, b_{15} 163°, $n^{23.5}_D$ 1.4688, $d^{22.5}_4$ 0.9972. C. A. S.

Synthesis of some monosubstituted homologs of cyclopentane having a normal side chain. A. F. Platé. *Compt. rend. acad. sci. U. R. S. S.* **24**, 257–62(1939) (in English). The following *1-alkylcyclopentanols* were prepd. from cyclopentanone and the appropriate alkyl-MgBr: Am, b_7 85–7°, n^{20}_D 1.4530, d^{20}_4 0.8957, yield 42.5%; hexyl, b_4 85–6°, n^{20}_D 1.4600, d^{20}_4 0.8921, yield 21–50%; heptyl, b_3 91–2°, n^{20}_D 1.4604, d^{20}_4 0.8817. Dehydration of these alcs. with 20% aq. $H_2C_2O_4$ or I (latter case) gave the following *1-alkylcyclopentenes:* Am, b_{743} 177–9°, n^{20}_D 1.4513, d^{20}_4 0.8128 (also given as 0.8108), yield 70–80%; hexyl, b_{743} 202–4.5°, n^{20}_D 1.4540, d^{20}_4 0.8158, yield 72% (dodecane probably accompanied this compd., thus explaining lower *n* and d. values of Zelinskiĭ, Mikhlina and Eventova (*C. A.* **27**, 5725)); heptyl, b_{762} 218–20°, n^{20}_D 1.4555, d^{20}_4 0.8176. Reduction of these olefins with Pd black gave the following *alkylcyclopentanes:* Am, b_{762} 178–9°, n^{20}_D 1.4356, d^{20}_4 0.7898; hexyl, b_{742} 201.1–2.2°, n^{20}_D 1.4394, d^{20}_4 0.7957; heptyl, b_{741} 222.1–4.0°, n^{20}_D 1.4430, d^{20}_4 0.8002. Cyclopentenyl chloride (85% yield from addn. of HCl to cyclopentadiene) and alkyl-MgBr react readily, giving the following *3-alkylcyclopentenes:* Am, b_{747} 173.5–5.2°, n^{19}_D 1.4455, d^{20}_4 0.8022, yield 43%; hexyl, b_{761} 196.8–8.8°, n^{19}_D 1.4480, d^{20}_4 0.8067, yield 38%. Hydrogenation of these latter compds. gave the following alkylcyclopentanes (see above): Am, b_{748} 178.4–9.6°, n^{20}_D 1.4359, d^{20}_4 0.7893; hexyl, b_{748} 200.8–2.0°, n^{19}_D 1.4392, d^{20}_4 0.7956. G. A.

Preparation and pyrolysis of cyclohexanone. Charles D. Hurd, Harry Greengard and Arthur S. Roe. *J. Am. Chem. Soc.* **61**, 3359–60(1939).—Passing the vapors of 150 g. cyclohexanol over pumice coated with the Adkins Cu chromite catalyst at 290–310° gives 12 g. cyclohexene, 91 g. (60%) of cyclohexanone (I) and 30 g. of residue. Refluxing 24 g. I for 115 hrs. gives 20 g. I and 2.5 g. of cyclohexylidenecyclohexanone, b_{20} 158–62°. Pyrolysis of I at 700–25° gives no ketene; some cyclohexadiene was identified. Decompn. of I in the ketene lamp (*C. A.* **30**, 5182[6]) during 1 hr. also gave no ketene. C. J. West

Hydrogenation of acetophenone to cyclohexylmethyl-

carbinol in the presence of solvent. V. N. Ipatieff and B. B. Corson. *J. Am. Chem. Soc.* **61**, 3292(1939).—A 3350-cc. bomb was charged with 200 cc. PhAc, 400 cc. isopentane, 40 g. Ni catalyst and 100 kg./sq. cm. H and rotated 6 hrs. at 100°; the products consisted of 20% (by vol.) of PhEt, 7% of an intermediate fraction (b. 137-89°) and 70% of cyclohexylmethylcarbinol (I), b_{761} 189.4-9.8°, n_D^{20} 1.4677, d_4^{20} 0.925. At 75° the product contained 8% PhEt and a 50/50 mixt. of I and PhMeCHOH; at 50° the product was largely unchanged PhAc. In the absence of solvent and using reduced Cu as catalyst at 225° the product was 75% PhEt. Using cyclohexane as solvent at 100° the product was a mixt. of PhEt, the 2 alcs. and PhAc. C. J. West



Addition of compounds to dicyclohexylamine. Charles F. Winans. *J. Am. Chem. Soc.* **61**, 3591-2(1939). -Dicyclohexylamine (I) and cyclohexanol (II) in petr. ether give an *addn. compd.*, m. 47-8°; other *addn. compds.* of I were prepd. as follows: *2-methylcyclohexanol*, m. 59-60°; *1,2-cyclohexanediol*, m. 64-6°; *1,3-isomer* (III), m. 64-6°; *1,4-isomer*, m. 90-1°; *o-cyclohexylcyclohexanol*, m. 43-5°; *p-tert-butylcyclohexanol*, m. 75-6°; those with *p-phenethyl alc.*, *1,3-butanediol* and *PhCH₂OH* m. below room temp. but the existence of compds. was shown by the analysis of the melts. The compds. of $(PhCH_2)_2NH$ with II, *piperidine* with III and *cyclohexylamine* with II also m. below room temp. C. J. West

Absorption spectra of some substituted nitrosobenzenes. Evidence for the mesomeric effect. Herbert H. Hodgson. *J. Chem. Soc.* **1939**, 1807.—Absorption spectra in 4×20^{-4} *M* EtOH (values for peak of band (A) and extinction coeff. (ε) are given): PhNO 3160, 1750; *o*-EtO deriv. 3800, 1875; *o*-I deriv. 2930, 2187; *o*-Br deriv. 2900, 3125; *o*-Cl deriv. 2880, 3281. Relative to PhNO the shifts of the *o*-derivs. are in the order of the neg. inductive (−*I*) effects, I < Br < Cl. The relatively small displacement difference would appear to indicate in each case the existence of pos. mesomeric (+*M*) effects of the order Cl > Br > I which, while opposed to the (−*I*) effects, do not exceed them. In the case of the EtO deriv. the feeble (−*I*) effect of the group is completely exceeded by a powerful pos. effect which must be ascribed to the pos. (mesomeric) polarization produced by the EtO groups. C. J. W.

Light absorption and structure of Schiff bases. Éva Varga. *Magyar Chem. Folyóirat* **45**, 83-99(1939). —Absorption spectra between 200-460 mμ have been detd. in a soln. of abs. alc. by means of a Zeiss spectrograph, between 400-500 mμ by means of a quartz prism of the same app. and above 460 mμ by means of a Konig-Martens photometer. The values of mol. extinction were calcd. on the basis of the law of Beer-Lambert. The results proved that azomethines alone have no specific selective light absorption. In case of the Schiff bases the aldimine-anamine tautomery is present at any time when a quinoid transformation of the mol. takes place. Thus a new band appears at 440 mμ. In case of 3-hydroxybenzalamines this new band could not be observed. The transformation $RCH{:}NCH_2R' \rightleftarrows RCH_2N{:}CHR'$ did not take place even in the case when this translocation would form a conjugated system (e. g., quinonimine structure). The characteristic band of 2- and 4-hydroxybenzalamines seems to be due neither to a "H bridge" nor to a hetero chain. It possibly may result from the formation of a quinoid ring structure. The possibility of a hetero ring seems improbable. S. S. de Finály

Reactions of anils. II. Addition of methyl ketones to benzalaniline in the presence of boron fluoride. H. R. Snyder, H. A. Kornberg and J. R. Romig. *J. Am. Chem. Soc.* **61**, 3556-8(1939); cf. *C. A.* **32**, 8390⁸.—PhCH:NPh (I) and $BF_3.Et_2O$ (II) in Et_2O give the *complex* $I.BF_3$ (III), yellow, m. 135-45°. III (1.5 g.) in 25 cc. Me_2CO gives 0.5 g. of 1-anilino-1-phenyl-3-butanone (IV), m. 88-9°; MeEtCO gives the pentane analog (V), m. 120-1°; I in MeEtCO (without BF_3) is recovered unchanged. It is not necessary to isolate III and the reaction is effected conveniently by adding II to a soln. of I in excess of the ketone in an ice bath; after 5 min. the compd. is pptd. by H_2O; II is not a true catalyst, for with mole ratios of BF_3 to I of 0.1, 0.32, 0.5 and 0.75 the yields of IV were 0, 20, 38 and 67%, resp. Using this method IV results in 67% and V in 66% yields; other *amino ketones*, $RCOCH_2CHPhNHPh$, were prepd. from the following: *iso-BuAc*, m. 80-1°, 60%; *AmAc*, m. 78-9°, 38%; *4-methyl-2-hexanone*, m. 72-3°, 38%; $PhCH_2CH_2Ac$, m. 98-8.5°, 26%; *pinacolone*, m. 148-9°, 71%; *cyclopentanone*, m. 163-4°, 42%; PhAc, m. 166-7°, 62%; $CH_2(CO_2Et)_2$, m. 98-9°, 6%. Neg. results or impure products were obtained with Et_2CO, Bu_2CO, dinonyl ketone, PhCN, PhC:CH, AcOEt, $MeNO_2$, acetomesitylene, mesityl oxide, $PhCH_2Ac$, cyclohexanone, α-tetralone and $AcCH_2CO_2Et$. Methone and $NCCH_2CO_2Et$ gave the benzal derivs.; however, this does not involve hydrolysis of the anil, since AcCH CHPh and $PhNH_2$ do not react. The addn. of Me ketones to III is not a reversible process.

III. A new type of Diels-Alder reaction. H. R. Snyder, R. B. Hasbrouck and J. F. Richardson. *Ibid.* 3558-60.—2-Ethyl-2-hexanal and $PhNH_2$, heated 1 min. on the sand bath and allowed to stand 15 min. at room temp., give 75% of *2-ethyl-2-hexenalaniline* (I), $PrCH{\cdot}CEtCH\ NPh$, b_2 127-8°, d_{20}^{20} 0.9379, n_D^{20} 1.5596. Equimol. quantities of maleic anhydride and I in C_6H_6 (1300 cc. per mole anhydride), allowed to stand 2 hrs. and refluxed for 3 hrs., give 75-80% of *5,7-diethyl-2-phenyl-2-azabicyclo[2.3.1]-6-octene-3-one-8-carboxylic acid* (II),

m. 145-6°. Catalytic reduction of II with PtO_2 and H (3 atm. pressure) gives 90% of the *dihydro deriv.* (III), m. 177° (monohydrate, decomps. 120-30°); the *amide*, prepd. through the chloride, m. 187-8°. II or III could not be hydrolyzed by boiling with acid or alkali (recovered unchanged after boiling 10 days with 10% KOH); fusion of 20 g. II with 20 g. KOH in 20 cc. H_2O gives 2.5 g. of 3,5-$Et_2C_6H_3CO_2H$ (IV), m. 133°. The reaction occurs through tautomerization of the anil and addn. of the anhydride to the diene system of the resulting enеamine. The mechanism of the formation of IV is also outlined. The work of Bergmann (*C. A.* **33**, 5914) with cinnamalaniline is confirmed, except that under highly anhyd. conditions the yield of maleanilic acid is negligible; the failure of this compd. to undergo condensation with maleic anhydride supports the formulation given for the reaction of I; because the ε-C atom is part of the C_6H_6 ring, cinnamalaniline is unable to undergo the initial tautomerization

IV. The reactions of benzalaniline and cinnamalaniline with methyl acetylenedicarboxylate. H. R. Snyder, Harry Cohen and Wm. J. Tapp. *Ibid.* 3560-1.—Benzalaniline (I) (14 g.) and $(CCO_2Me)_2$ (II) (8 g.) in 50 cc. abs. Et_2O and 2 cc. H_2O, allowed to stand 2 days at room temp., give 3.8 g. of *Me α-benzal-α'-phenyliminosuccinate*, m. 192-3°; the same product is obtained from I and Me oxalacetate (III) or from BzH, $PhNH_2$ and III or II. That the yield is improved by the addn. of a small quantity of H_2O suggests that the reaction involves hydrolysis of the anil. Cinnamalaniline (IV) and II in petr. ether, refluxed 2 days, give 23% of the *compd.* $C_{27}H_{25}O_8N$, yellow, m. 166-7°; this corresponds to 1 mole of anil to 2 of II. If a mixt. of 1.4 g. of II and 2. g. of IV is kept at 0° for 4 hrs. and at room temp. for 2 weeks, washed with petr. ether and crystd. from 15 cc. PhMe, there is obtained 0.05-0.1 g. of an *isomer*, m. 309-10°; addn. of petr. ether to the PhMe gives 20% of the isomer m. 166-7°. In the absence of solvent the reaction is highly exothermic. C. J. W.

Nickel as a catalyst for the hydrogenation of aromatic halogen compounds. Charles F. Winans. *J. Am. Chem. Soc.* **61**, 3564-5(1939).—The following typical conditions are used for the reductions: 300 g. *p*-$ClC_6H_4NO_2$, 400 ml. EtOH and 15 g. Raney Ni in an autoclave at 100 atm. H pressure were slowly heated to about 50°; when the pressure had fallen to 20 atm. more H was admitted; after 23 min. the reduction was complete; the yield of *p*-$ClC_6H_4NH_2$ was 97%; even at 150° the yield was nearly quant. Other compds. are not as stable. In many cases the catalyst may be reused as many as 6 times; catalysts no

longer sufficiently active for more difficult hydrogenations served well in simpler conversions. *m*- and *p*-$ClC_6H_4NO_2$ give 90.3 and 97% of *m*- and *p*-$ClC_6H_4NH_2$; *p*-$BrC_6H_4NO_2$ gives 83% of *p*-$BrC_6H_4NH_2$; *o*-$IC_6H_4NO_2$ gives 23% of *o*-$IC_6H_4NH_2$, the main reaction product being $PhNH_2$; 2,5-$Cl_2C_6H_3NO_2$ gives 97% of 2,5-$Cl_2C_6H_3NH_2$ but 2,4-$(O_2N)_2C_6H_3Cl$ gives 91% of *m*-$C_6H_4(NH_2)_2$; *o*-chlorobenzaldazine gives 81% and *o*-chlorobenzalaniline gives 65.5% of *o*-$ClC_6H_4CH_2NH_2$. Benzal-2,5-dichloroanil yields 91% of *benzyl-2,5-dichloroaniline*, m. 44–5°. *o*-ClC_6H_4CHO and excess NH_3 give 87.5% of *o*-$ClC_6H_4CH_2NH_2$. *p*-BrC_6H_4Bz (I) gives 72% of *p*-bromobenzohydrol and the oxime of I yields 88.5% of *p-bromobenzohydrylamine*, m. 126°. *p*-ClC_6H_4CN gives 64% of *p*-$ClC_6H_4CH_2NH_2$ and 21% of (*p*-$ClC_6H_4CH_2)_2NH$. PhCl does not give chlorocyclohexane, small quantities of C_6H_6 being formed. $PhCH_2Cl$ gave some diphenylethane. C. J. West

Chemistry of *p*-hydroxyphenylisopropylmethylamine or veritol. Rosa C. D'Alessio de Carnevale Borsino. *Semana méd.* (Buenos Aires) **1939, II**, 1314–23.—For quant. detn. dissolve 0.1 g. of veritol (I) in 10 cc. H_2O and 15 cc. EtOH and titrate with 0.1 *N* NaOH, using phenolphthalein; add rosolic acid and titrate with 0.1 *N* H_2SO_4 to yellow. Both titrations must be identical if the substance is pure. The factor per cc. is 0.0128. Differentiation from hordenine (II), tyramine (III) and tyrosine (IV) was tried, making use of 22 different reagents; but most gave identical reactions. The following color reactions may be used: Cl water and NH_3 give with I red, with II light yellow, with III yellow with green fluorescence, with IV red. HIO_3 gives with I and III red, with II and IV neg. H_2O_2 with I and III red, with II and IV neg. Tyrosinase gives with I, III and IV red, with II neg. Colorimetric estns. of veritol may be effected with the diazo reaction, using either sulfanilic acid or *p*-nitroaniline, or with Wavelet's reagent, which gives a blue color in the presence of NH_3. A. E. Meyer

New color reaction for diarylamines. E. Marshall Meade. *J. Chem. Soc.* **1939**, 1808. Addn. of MeMgI to an amine in PhOMe, followed by BzCl, gives a red color if a diarylamine was originally present; it will det. 1% of Ph_2NH in Ph_2NMe. Pos. results were obtained with Ph_2NH, 4-$MeOC_6H_4NHC_6H_4Me$-4, (4-$MeOC_6H_4)_2NH$, Ph-(α-$C_{10}H_7$)NH and (*o*- and *p*-$MeOC_6H_4$)(β-$C_{10}H_7$)NH. C. J. West

Identification of organic acids by the use of *p*-chlorobenzylpseudothiuronium chloride. Bartlett T. Dewey and Robert B. Sperry. *J. Am. Chem. Soc.* **61**, 3251–2 (1939). *p-Chlorobenzylpseudothiuronium chloride* (I) results on refluxing 161 g. *p*-$ClC_6H_4CH_2Cl$ and 76 g. $CS(NH_2)_2$ in 200 cc. EtOH for 30 min., and recrystg. from a mixt. of equal parts of concd. HCl and H_2O; I m. 197°. The following salts were prepd. from a 10% EtOH soln. of I and an aq. soln. of the Na or K salt of the acid; they may be recrystd. from dioxane. There is not sufficient diversity in m. p. to make these salts satisfactory derivs. of general application. The m. ps. are cor. *Acetate* 140°, *butyrate* 139°, *caproate* 143°, *formate* 148°, *chloroacetate* 158°, *oleate* 131°, *oxalate* 194°, *palmitate* 146°, *propionate* 143°, *succinate* 167°, *trichloroacetate* 148°, *valerate* 142°, *benzenesulfonate* 184°, *benzoate* 155°, *o*-, *m*- and *p*-*bromobenzoates* 165, 161 and 172°, *o*-, *m*- and *p*-*chlorobenzoates* 159, 157 and 173°, *cinnamate* 167°, *o*-, *m*- and *p*-*iodobenzoates* 162, 154 and 177°, *phthalate* 166°, *salicylate* 162°, *sulfosalicylate* 181°, *o*-, *m*- and *p*-*toluate* 150, 151, 161°, *p-toluenesulfonate* 193°. C. J. West

The reactions and salts formed by phenylglycine, nitrosophenylglycine, phenylglycine-*o*-carboxylic acid and 1-aminoacridine-4-carboxylic acid. J. V. Dubský, E. Tesařík, Št. Rusňák, A. Okáč and V. Šindelář. *Chem. Listy* **33**, 346–52(1939).—Phenylglycine formed the salts RAg (R = $PhNHCH_2CO_2$), $R_2Pb.7H_2O$, white plates, m. 108° and decompg. 174°, $R_2Cu.H_2O$, pale-blue crystals decompg. at 174°, R_2Cu, dark-green crystals decompg. 182°, $R_2Cu.2NH_3$, R_3Fe, $R_4Cr_3(OH)_2.10H_2O$, stable at 320°, $R_4CO_2(OH)_2$, solid at 320°, $R_2Zn.2H_2O$, and $R_3Ca_2OH.7H_2O$. Nitrosophenylglycine, m. 100°, sol. in EtOH and warm H_2O, formed pale-yellow needles, reacted with Hg^+ to form $C_8H_7O_3N_2Hg$ and did not react with any other cations. Phenylglycine-*o*-carboxylic acid formed $Hg(C_9H_7NO_4).5H_2O$, $HgC_9H_7NO_4$, $AgC_9H_8O_4N$, $Ag_2C_9H_7O_4N$, $Pb(AcO)_2.PbC_9H_7NO_4.9H_2O$,

$C_9H_7NO_4.10H_2O$,

$C_9H_7NO_4.5H_2O$,

$FeOH.4H_2O$, decomps. 305°, insol. in H_2O, sol. in EtOH with difficulty, and

$Fe_2.4.5H_2O$, a blue powder insol. in H_2O and sol. in EtOH with difficulty. 1-Amino-4-acridinecarboxylic acid did not enter into any typical reactions with cations. Frank Maresh

Hydrogenation of aldehydes in the presence of ammonia. Charles F. Winans. *J. Am. Chem. Soc.* **61**, 3566–7(1939).—The hydrogenation of aldehydes, such as BzH, contg. no reactive H on the α-C atom, in EtOH-NH_3 soln. may be accomplished at temps. below 75°. By suitable control of the ratio of aldehyde to NH_3, the product may be predominantly primary (I) or secondary amine (II). Using 3 g.-mole of BzH to 51 g. (3 moles) in 300 ml. cooled alc. and 10 g. Raney catalyst in a hydrogenation autoclave with an initial H pressure of 90 atm., absorption starts at 40° and in 0.5 hr. is complete at a final temp. of 70°; distn. gives 89.4% $PhCH_2NH_2$ (III) and 7.1% of $(PhCH_2)_2NH$ (IV); with 0.5 and 0.66 equiv. NH_3 the yields are 11.8 and 80.8 and 30.5 and 62.6%, resp. Using 0.5, 0.66 and 1 equiv. NH_3 *o*-MeC_6H_4ClIO gives 11.2, 30.8 and 82.6% I and 81.7, 63.1 and 15.5% II; *o*-ClC_6H_4CHO gives 3.6, — and 87.5% I and 84.6, — and 7.6% II; furfuraldehyde gives 12.2, 30.3 and 79% I and 65.5, 66.5 and 6% II. Hydrobenzamide (V) gives 30.7% III and 60.9% IV; V with excess NH_3 gives 81% III and 8% IV; 0.37 mole each of V and BzH give 11.7% III and 67% IV. Hydrofuramide (VI) gives 29.4% furfurylamine (VII) and 62.8% of difurfurylamine (VIII); VI and excess of NH_3 give 62.5% VII and 12.4% VIII; VI and furfural (0.75 mole each) give 16.4% VII and 60.5% VIII. The results show that the proportions of products depend on the ratio of the reactants and not on the method of addn. The use of aliphatic aldehydes should presumably lead to similar results but the formation of tarry by-products through the aldol reaction or other condensation largely masks the production of amines. C. J. West

Diazo chemistry. Herbert H. Hodgson. *Rec. trav. chim.* **58**, 928–30(1939)(in English); cf. *C. A.* **33**, 4211⁴. —A further reply by H. to the claims of priority by Schoutissen. C. J. West

Decomposition reactions of the aromatic diazo compounds. VII. Some reactions of diazonium chlorides with esters and nitriles. W. E. Hanby and Wm. A. Waters. *J. Chem. Soc.* **1939**, 1792–5; cf. *C. A.* **33**, 6263⁸.—Solid *p*-$ClC_6H_4N_2Cl$ (from 20 g. *p*-$ClC_6H_4NH_2$) in AcOMe gives 2.8 g. of PhCl and 0.1 g. *p*-$C_6H_4Cl_2$; in AcOEt the yields were 1.1 and 0.5 g.; in AcOPr 0.5 and 1.2 g.; in AcOAm there were no simple reaction products; in all cases the chief product is a complex black tar. The decompn. of PhN_2Cl in AcOAm, Pr propionate and BzOMe did not commence until the mixt. had been heated to nearly 100° and then tended to become uncontrollable; the same is true in Bu_2O or Am_2O. PhN_2Cl under AcOMe reacts vigorously with both Sb and Zn, giving metallic chlorides and with Sb (*p*-$ClC_6H_4)_3SbCl_2$ but there was no reaction under AcOAm; under BzOMe, PhN_2Cl reacts with Zn and under AcOEt it reacts slowly with Te but gives no appreciable quantity of org. tellurides. If the diazo compd. is washed with Et_2O and this is not completely removed, AcH is formed, probably due to the dehydrogenation of Et_2O by a free radical. On decompn. in

MeCN the ArN_2Cl also yields small quantities of ArNHAc and traces of ArAc may also be formed. PhN_2Cl (from 22 g. $PhNH_2$.HCl) gives 3 g. PhNHAc, 0.1 g. Ph_2 and a trace of PhAc. Zn and Sb bring about the reaction at room temp. Rapid heating, even in the absence of metals, decreases the yield of PhNHAc. Yields are given for various other diazonium chlorides. These reactions seem to indicate that addn. to the CN group can occur. All of these reactions are consistent with the view that a certain amt. of decompn. of the diazonium chloride to neutral radicals can occur in these solvents. VIII. **The diazocyanides.** Oliver Stephenson and Wm. A. Waters. *Ibid.* 1796–804.—The reactions of diazocyanides in nonaq. solvents have been studied in order to discover to what extent the theories postulated for the mechanisms of decompn. of diazoacetates, diazohydroxides and diazonium chlorides can be generalized. The following new *diazocyanides* are reported: *o-chlorobenzene-syn* (I), orange, m. 49°; *antiisomer*, bright red, m. 78°; *4-chloro-o-toluene-syn* (II), orange-yellow, m. 49°; *antiisomer*, red, m. 68°; *5-chloro-o-toluene-syn* (III), orange, m. 60°; *antiisomer*, red, m. 75°. Dry specimens of the syn compds. could be kept for some days in the dark but damp specimens gave off HCN and formed tarry products contg. only a little of the anti isomer. Freshly prepd. EtOH solns. of the syn compds. reacted immediately with EtOH-$AgNO_3$, pptg. AgCN and leaving practically colorless diazonium nitrate solns. which would couple with alk. β-$C_{10}H_7OH$; after a short time the EtOH solns. turned reddish brown and then would not couple; acidified solns. did not change color on keeping. EtOH solns. of the anti compds. gave no immediate ppt. but on exposure to light AgCN was gradually formed and the soln. became paler. Solns. of the anti compds. in EtOH or Me_2CO when kept for several days in daylight darken considerably and gradually evolve N_2, showing that a slow decompn. occurs; those kept protected from light show little change; the final photochem. decompn. products of the anti compds. are identical with the thermal decompn. products of the syn compds. Metallic Cu undoubtedly influences the course of the decompn. of the syn compds. but it has no obvious direct action upon the anti compds. On warming I in 100% EtOH there results 20% of PhCl and a trace of the anti compd.; Cu gives 20% PhCl and a trace of *o*-ClC_6H_4CN; III gives 15% of *m*-MeC_6H_4Cl and with Cu 25% *m*-MeC_6H_4Cl and 1% of 5-chloro-*o*-tolunitrile; Hg, Sb and Zn did not affect the decompn. In Me_2CO the syn compds. yielded HCN, tar and some anti compd.; AcOMe solns. behaved similarly; in the presence of Cu there was no free HCN but nitriles were formed; I gave 4% PhCl and 10% *o*-ClC_6H_4CN and II 6% *p*-ClC_6H_4Me and 9% of 4-chloro-*o*-tolunitrile. In CCl_4 all syn compds. isomerized to the pure anti compds., and this method was used for their prepn.; with Cu, N and HCN are evolved on gentle warming and CuCl and $CuCl_2$ are formed; the Cu is attacked even in the presence of $CaCO_3$; Ag, Hg, Fe, Pb or Zn does not cause decompn. The syn compd. (IV) from *p*-$ClC_6H_4NH_2$ gives 9% *p*-$C_6H_4Cl_2$; I gives 14% *o*-$C_6H_4Cl_2$; that (V) from *p*-$BrC_6H_4NH_2$ yields 10% *p*-ClC_6H_4Br; II gives a little nitrile and 15% 2,4-$Cl_2C_6H_3Me$ and III gives 20% of 2,5-$Cl_2C_6H_3Me$. In dry C_6H_6 Cu causes the evolution of N and HCN but the Cu is not attacked; IV gives 1.5% of 4-ClC_6H_4Ph; I gives 7% of *o*-ClC_6H_4CN and 3% of crude 2-ClC_6H_4Ph; V gives 5% of *p*-BrC_6H_4CN and 1% of 4-BrC_6H_4Ph; II and III gave only traces of nitriles. There was no reaction with Ag or Zn; Fe causes a slight evolution of N and a trace of 4-ClC_6H_4Ph was isolated from IV. Reaction in dry Et_2O was difficult to control; the solns. tend to decomp. violently upon evapn. to dryness; AcH was always formed and so was HCN; I gives 6% PhCl and 3% *o*-ClC_6H_4CN; V gives 6% PhBr and 3% of the nitrile; II gives 8% of *p*-ClC_6H_4Me and 4% of nitrile; III yields 10% of *m*-ClC_6H_4Me and 2% of nitrile. A table gives the percentage of N evolved and of tar formed from the 5 syn compds. in the various solvents (with and without Cu). The following conclusions are drawn: anti compds., though thermally stable, may be converted photochemically into the isomeric, reactive syn compds. 1 The syn compds. exist in EtOH soln. in tautomeric equil. with diazonium cyanides; neutral solns. easily give self-coupling products consequent upon a hydrolysis in which free HCN is liberated; solns. in non-ionizing solvents isomerize to the anti compds. even in the absence of light. Cu appears to be the only metal which catalyzes the decompn. of the syn compds. In non-ionizing solvents (CCl_4, C_6H_6, Et_2O) syn compds. yield free radicals upon warming with Cu, the respective final products being RC_6H_4Cl, RC_6H_4Ph and RPh plus AcH, together with, in each case, HCN; only in CCl_4 does the Cu appear to be attacked. The main reaction product is always a black tar which is not a polyazo compd. Hantzsch's theory (H. and Schultze, *Ber.* **28**, 666(1895)) that the syn compds. decomp. to give vicinal radicals which promptly unite does not accord with the exptl. facts. It appears that the radicals formed by the decompn. of the syn 3 compds. react with neighboring solvent mols. and therefore must have an independent free existence. **IX. Note on oxidation mechanism.** Wm. A. Waters. *Ibid.* 1805–7.—Benzenediazoacetate (I) is insol. in cyclohexene (II) but, when stirred under II, I gradually decomps., giving chiefly tar. The II layer yields a small quantity of 2-cyclohexenyl acetate (III) and traces of other unsatd. substances of high b. p. III also results by the decompn. of aq. PhN_2Cl in a mixt. of II and Me_2CO contg. an excess 4 of AcONa, whereas decompn. of the solid in the same 2 solvents in the presence of $CaCO_3$ affords 2-cyclohexenyl chloride. These reactions are evidently substitutions of the reactive CH_2 group of II by the AcO and Cl radicals derived from the decompg. diazo compds. Analogous to these reactions are the oxidation of II by $Pb(OAc)_4$ and by O_2 in the presence of Os. It is suggested that all these reactions have a common mechanism in which neutral 5 radicals are involved. C. J. West

Transformations of dulcin. C. Alberti. *Atti X° congr. intern. chim.* **3**, 21–6(1939); cf. *C. A.* **33**, 7283².—In order to obtain *chloroacetyl-* (I) or *bis(chloroacetyl)dulcin* (II) and further to det. the effect on the sweet taste that a hydantoin nucleus would have, A. treated $ClCH_2COCl$ (III) with the Mg bromide deriv. (IV) of dulcin (V). IV (from 2.4 g. Mg, 11 g. EtBr and 9 g. V) and 6 g. freshly distd. III were boiled 9 hrs. The Mg complex was de- 6 compd. with ice and the soln. alkalized with $NaHCO_3$. I, m. 181–2° from Me_2CO, insol. in H_2O or Et_2O, pptd. The ether soln. was dried over anhyd. Na_2SO_4 (VI) and treated several times with 5% Na_2CO_3 and finally washed with H_2O. Dried over VI and concd. the soln. (in a H_2SO_4 desiccator) finally yielded 0.5 g. *N-p-phenetylhydantoin* (VII), m. 201–2°. VII is insol. in H_2O, very slightly sol. in petroleum solvents, slightly sol. in Et_2O and C_6H_6, sol 7 in MeOH and EtOH and very sol. in Me_2CO, insol. in acids, sol. in 20% NaOH. Boiling VII with 5% $Ba(OH)_2$ in alc. gave *N-dulcinylacetic acid* (VIII) ($EtOC_6H_4N(CONH_2)CH_2CO_2H$), m. 179–80°, almost insol. in C_6H_6, Et_2O and petr. solvents, sol. in EtOH, MeOH, Me_2CO, NH_3 and dil. alkalies. VIII (0.0736 g.) is equiv. to 2.92 cc. 0.1 *N* KOH with methyl red. The NH_4 salt of VIII with Ag, Pb, Hg and Cu gives the corresponding salts. I was also prepd. from the mono-Mg bromide deriv. of 8 V. Complete hydrolysis of I was accomplished by boiling with 0.5 *N* alkali or acids and the final products were V, HCl and $CH_2(OH)CO_2H$, the latter identified by the method of Denigès (cf. *Bull. soc. chim.* [4], **5**, 648(1874)). It was impossible to obtain II irrespective of the proportions of the reactants used and the length of heating. The products resulting always were I and VII. None of the new derivs. showed any sweet taste as might have been expected from the sweetness of their constituent radicals. J. C. Lo Cicero

Synthesis of organobismuth compounds. Henry Gilman and Alexis C. Svigoon. *J. Am. Chem. Soc.* **61**, 3586(1939).—*p*-$MeC_6H_4N_2Cl$ (from 10.7 g. *p*-$MeC_6H_4NH_2$) and 0.1 mole $BiCl_3$ in 16 cc. concd. HCl, pptd. with an ice-cold mixt. of MeOH-EtOH, give the Bi complex, $C_{21}H_{21}N_6BiCl_6$; this is pptd. by MeOH or EtOH and more effectively with the mixt. of the 2. The complex (32.5 g.) in 100 cc. cold Me_2CO, treated with 52.8 g. Cu powder

and after 0.5 hr. with an equal vol. of 25% NH_4OH and dild. to 450 cc. H_2O, gives 3.07 g. of $(p\text{-}MeC_6H_4)_3Br$. C. J. West

Intramolecular substitution as a means of comparing activating and deactivating effects. Jessie D. C. Mole and E. E. Turner. *J. Chem. Soc.* **1939**, 1720–4.—The effect of substitution on the reactivity of the aromatic nucleus can be studied not only by nitration expts. but also by ring closures. The conversion of a no. of substituted *o*-phenoxyphenyldichloroarsines into 10-chlorophenoxarsines has been investigated and the rate of cyclization correlated with the nature and position of the

2',4'-di-Me isomer, pale yellow, m. 61–2° (78%); *2-nitro-4'-methoxydiphenyl ether*, pale yellow, m. 75–6.5°. The NO_2 compds. were reduced at 100° with excess of Fe tilings and H_2O in presence of a little AcOH; *2-Amino-2',5'-dimethyldiphenyl ether*, m. 56–7° (77%); *2',5'-isomer*, b_{14} 213–14° (83%) (*HCl salt*, m. 178–9°); *2',4'-isomer*, m. 64–5° (80%); *2-amino-4'-methoxydiphenyl ether*, b_{21} 212–13° (*HCl salt*, m. 169–70°). Arsonic acids were prepd. by the method of Roberts and Turner (*C. A.* **20**, 175); the yield obtained varied from compd. to compd. and with the temp. of mixing (the optimum temp. is given); *2-o-tolylbenzenearsonic acid*, 50–60°, m. 184–5°, 30–35% yield; *m-isomer*, 50–60°, m. 193–4°, 30–40%; *2-(2',5'-dimethylphenoxy)benzenearsonic acid*, 90°, m. 178–9°, 12%; *2',5'-di-Me isomer*, 50–60°, m. 177.5–8°, 13%; *2',4'-di-Me isomer*, 90°, m. 184–5°, 12–16%; *2-p-anisyloxybenzenearsonic acid* (VI), 50°, m. 188–9°, 11%. *2-p-bromophenoxybenzenearsonic acid*, 55–60°, m. 183–4°, 20%. The dichloroarsines were also prepd. by the method of R. and T. and were purified through the oxides, which were warmed with fuming HCl; liquid products were extd. with $CHCl_3$. *2-o-Tolyloxyphenyldichloroarsine* (I), m. 73–4°; *m-isomer* (II), oily; *p-isomer* III), m. 73°; *2-(3',5'-dimethylphenoxy)phenyldichloroarsine* (IV), m. 71.5–3°; *2',5'-isomer* (V), m. 70–71.5°; *2',4'-isomer* (VI), m. 52.5–4°; *2-p-anisyloxyphenyldichloroarsine* (VII), m. 63–4°; *2-p-Br analog* (VIII), m. 76–7°. Ring closure was followed at different temps., the HCl produced during definite intervals of time being detd.; the 1st-order reaction equation gives reasonably trustworthy values for velocity consts., although with some of the slower reactions there was a brief period of induction and rate consts. in these cases only have a semi-quant. significance. The following figures are the reaction temp. and $k \times 10^4$ ($min.^{-1}$). 150°: I 6, III 12, IV 100, V 48. 160°: *o*-$PhOC_6H_4AsCl_2$ (IX) 13, I 18, II 100, III 30, IV 170, V 70, VI 24. 175°: I 40, II 160, III 74. 180°: IX 40, I 47, II 230, III 110, IV 600, V 140, VI 66, VII 61. 190°: VII 83, *p*-$ClC_6H_4OC_6H_4AsCl_2$-*o* (X) 9.5, VIII 10. 200°: IX 97, I 120, III 270, VI 165, VII 110, X 17, VIII 19. 210°: IX 140, X 33, VIII 45. *10-Chloro-4-methylphenoxarsine*, m. 90–1°; *3-Me isomer* (XI), m. 140–1°; *1,3-di-Me deriv.*, m. 138–9°; *1,4-di-Me deriv.*, m. 146–7°; *2,4-di-Me deriv.*, m. 130–1°; *2-MeO deriv.*, m. 108–9°; *2-Br deriv.*, m. 172–3°. The structure of XI follows from the following synthesis: 3,4-$Cl(O_2N)C_6H_3Me$ gives 50% of 2-nitro-5-methyldiphenyl ether; $SnCl_2$ reduction gives 77% of *2-amino-5-methyldiphenyl ether*, yellow, b_{15} 213–14°; the Hg diazonium salt was decompd. at −70° over a period of 20 hrs. and the product heated with $AsCl_3$; the resulting oil was then heated for 6 hrs. at 200° in a stream of CO_2, giving XI. In explaining the mechanism of ring closure, it is probable that the As—Cl bond becomes polarized, the cyclization process then resolving itself into

$$\overset{\delta+}{\text{As}}\text{—}\overset{\delta-}{\text{Cl}}$$

the attack of the electrophilic reagent, $-AsCl_2$, on the opposed aromatic nucleus. The results show that this "internal" electrophilic reagent places activated and deactivated centers in aromatic systems in the same order as that given by an external reagent such as HNO_3. All mono-Me compds. (I-III) are more easily cyclized than IX; moreover, II is much more readily cyclized than III and the latter is much more readily cyclized than I, which, in turn, is more rapidly cyclized than IX in spite of the decreased no. of possible fruitful collisions. That this factor does influence rates of ring closure is clear from a comparison of I and III, in which the activation by Me of the reacting position or positions is approx. equal, I, however, having only half as many collisions as III between the reacting atoms. The great reactivity of IV is to be expected; the greater speed of cyclization of V than of VI is interesting in comparison with the sulfonation of *p*- and *m*-xylenes. The inability of a mesomeric effect to activate the *m*-position should mean a comparatively slight difference between the rate of cyclization of IX and VII; actually, the latter is slightly the more reactive. The results for X and VIII clearly show the deactivating effect of Cl and Br. C. J. West

Action of nitrous acid on dimethylaniline-*p*-sulfonic acid in sulfuric acid. A. M. McKessar Davidson and Thomas H. Reade. *J. Chem. Soc.* **1939**, 1701–3; cf. Michler and Walder, *Ber.* **14**, 2176(1881).—*p*-$Me_2NC_6H_4SO_3H$ (I) (1 mole) in 4 *N* H_2SO_4 (cooled in ice), slowly treated with stirring with 4 moles of aq. $NaNO_2$, allowed to react 17–18 hrs. and the yellow ppt. extd. with petr. ether, gives as the sol. portion a mixt. of 4-$O_2NC_6H_4NMe_2$ (II) and 4-$O_2NC_6H_4NMeNO$ (III) (sepd. by washing with 5 *N* HCl) and as the insol. portion *3-nitro-4-dimethylaminobenzenesulfonic acid* (IV), pale-yellow needles; this was synthesized by heating 4,3-$Cl(O_2N)C_6H_3SO_3H$ and 33% aq. Me_2NH with Cu powder for 3–4 hrs.; the *anilide* of IV, m. 182°. Soly. of IV in H_2SO_4 at 14°: 0.5 *N* 0.5710 g., *N* 0.5660 g., 2 *N* 0.547 g., 3 *N* 0.5217 g., 4 *N* 0.4823 g., 5 *N* 0.4100 g. The yield of IV from I increases from 0.319 g.-mole to 0.380 g.-mole on increasing the concn. of the H_2SO_4 from 0.5 to 5 *N*; that of III increases from 0.0037 to 0.0547 g.-mole; that of II decreases from 0.052 to 0.005 (at 3 *N*). C. J. West

The transition of carbohydrates to carbocyclic compounds. I. The transformation of glucose into phenol. P. P. Shorygin and N. N. Makarova-Zemlyanskaya. *Compt. rend. acad. sci. U. R. S. S.* **23**, 915–18(1939)(in German).—Phenol is obtained in 0.55-g. yield by adding 2.7 g. Na to 3.86 g. 2,3,4-trimethyllevoglucosan, $O.CH_2.$-$CH.CH(OMe).CH(OMe).CH(OMe).CH.O$, in 45 cc. dry liquid NH_3, sealing the tube the following day, leaving it at room temp. for about 18 days, distg. off the NH_3, treating the reaction product with aq. Et_2O and with water, acidifying the soln., extg. it with Et_2O and fractionating the Et_2O residue under normal pressure. An explanation of the reaction mechanism may be found in previous investigations about the decompn. of ethers by Na and Na metalloörg. compds. (cf. *C. A.* **19**, 496) and in expts. not yet published concerning the formation of double bonds by the splitting off of NaOH. Styrene is, indeed, obtained in 75% yield by heating 1 mol. $PhCH_2CH_2OH$ with 0.5 g.-atom Na. Dora Stern

Catalytic synthesis of anisole and *p*-cresol methyl ether. Seiiti Isikawa and Masakatu Matuhasi. *Science Repts. Tokyo Bunrika Daigaku* **A3**, 249–55(1939)(in German).—The formation of anisole by conducting a soln. of phenol in MeOH over heated ThO_2 (formed from $Th(NO_3)_4$) has been investigated. It makes no difference whether the catalyst is deposited on cotton cloth or on asbestos, nor does an admixt. of CeO_2 influence the catalytic action. The highest yield (48% anisole) is obtained at 400° with 80 g. $Th(NO_3)_4$ per 94 g. phenol. At higher temps. (500°) increasing amts. of Ph_2O and xanthene (m. 99.2°, cor. Berl) are formed. The latter is also obtained by passing phenol or Ph_2O with HCHO over the catalyst. HNO_3 oxidizes it to xanthone, m. 173.1° (cor. Berl). The reaction between *p*-cresol and MeOH in the presence of heated ThO_2 yields *p*-cresol Me ether, *p*-tolyl ether, m. 50°, and 2,7-dimethylxanthene, m. 168.2° (cor. Berl). HNO_3 oxidizes the latter to 2,7-dimethylxanthone. Dora Stern

4,6-Dibromoresorcinol dimethyl ether. G. Lock. *Monatsh.* **72**, 373–7; *Sitzber. Akad. Wiss. Wien. Math.-naturw. Klasse*, Abt. IIb, **148**, 71–5(1939).—Hodgson and Dyson (*C. A.* **29**, 6585[9]) report a 4,6-dibromoresorcinol

di-Me ether (I) as m. 65°, whereas L. and Nottes (*C. A.* **30**, 5954[6]) found 140–1°. The action of Me_2SO_4 on 4,6-dibromoresorcinol (m. 116.5°) gives a I m. 141.5°. The Me ether of 2-nitroresorcinol (m. 130°) with Br without a solvent gives 60% of the di-Br deriv.; reduction with $SnCl_2$ in HCl-EtOH gives 92% of *2-amino-4,6-dibromoresorcinol di-Me ether*, m. 95°; removal of the NH_2 group by boiling the diazo compd. with EtOH gives a I m. 141.5°. The observation of H. and D. must be in error.

C. J. West

Improved methods for the nitrosation of *m*-halophenols and their conversion into benzoquinone monoximes Herbert H. Hodgson and Donald E. Nicholson. *J. Chem. Soc.* **1939**, 1808; cf. *C. A.* **34**, 7383. *m*-Halophenols (2 g.) in 25 cc. 50% AcOH, treated gradually below 20° with 4 g. $NaNO_2$ in 10 cc. H_2O give 80% of the 6-NO deriv. with the *m*-Cl and *m*-I derivs.; the *m*-Br deriv. gives a lower yield than in dil. H_2SO_4. The velocity of pptn. is greatest for the I and least for the Br deriv. Some of the NO_2 deriv. is also formed. *m*-Halophenols (2 g.) in 20 cc. AcOH and 2 g. $NaNO_2$ in 10 cc. concd. H_2SO_4 (heated previously to 70°), mixed at 20° and kept at 0° for 10 min.; the yield of the 3-halobenzoquinone 4-oximes is nearly quant.

C. J. West

***d*- and *l*-α-Phenylallyl alcohols and some of their reactions.** D. I. Duveen and J. Kenyon. *J. Chem. Soc.* **1939**, 1697–1701.—K., Partridge and Phillips (*C. A.* **31**, 3025[5]) showed that (−)-α-phenyl-γ-methylallyl H phthalate (I) is readily rearranged into (+)-γ-phenyl-α-methylallyl H phthalate with a large retention of optical activity and that (−)-α-phenyl-γ-methylallyl alc. and its esters readily undergo replacement reactions during which a similar rearrangement occurs although the retention of optical activity is of a lower order. It was concluded that a γ-Me group contributes an inductive effect favorable to liberation of an anion in these compds. In order to obtain comparative evidence of the influence exerted by the Me group in I, the optically active forms of α-phenylallyl alc. (II) have been prepd. and the behavior of II and some of its derivs. examd. II and $C_6H_4(CO)_2O$ in C_5H_5N at 50° for 3 hrs. give a *H phthalate* (III), m. 73–4°. Quinidine (484 g.) and 422 g. III in 1600 cc. Me_2CO give a ppt. which, crystd. 3 times from AcOMe, gives about 300 g. of the *l*-III *quinidine salt* (IV), m. 124° (decompn.), $[\alpha]_{5893}$ 128.9°, $[\alpha]_{5461}$ 155.8°, $[\alpha]_{4358}$ 279.5° ($CHCl_3$, *c* 5.010); the mother liquor from IV deposits the *d*-III *salt* (V) which, recrystd. from Me_2CO, m. 161–3° (decompn.), $[\alpha]_{5894}$ 106.8°, $[\alpha]_{5461}$ 127.9°, $[\alpha]_{4358}$ 235° ($CHCl_3$, *c* 5.101). IV, covered with Me_2CO and decompd. with a slight excess of cold dil. HCl, gives *l*-III, an oil, $[\alpha]_{6438}$ 33.6°, $[\alpha]_{5893}$ 12.6°, $[\alpha]_{5461}$ 51.4°, $[\alpha]_{4358}$ 93° (CS_2, *c* 5.376); data are also given for solns. in C_5H_5N, C_6H_6, AcOH, $CHCl_3$, MeOH and EtOH; in the homogeneous soln., α^{20}_{5893} 6.39°, α^{20}_{5461} 7.64°, α^{20}_{4358} 11.9° (*l* 0.25); the *d*-III from V is also an oil, $[\alpha]_{5893}$ −42.3°, $[\alpha]_{5461}$ −51.3°, $[\alpha]_{4358}$ −92.6° (CS_2, *c* 4.947). *l*-III on standing 4 months deposits the γ-isomer. Hydrolysis of *l*-III with a slight excess of aq. 5 *N* alc. KOH gives *l*-II, b_{16} 106°, n^{19}_D 1.5398, α_{5893} −20.08°, α_{5780} −21.55°, α_{5461} −26.01°, α_{4358} −60° (18°); the influence of temp. is shown by data for 10 temps. from 21° to 67° for α_{5893}, α_{5461}, α_{4358}. *d*-II b_{16} 107°, $n^{19.5}_D$ 1.5391, α_{5893} 20°, α_{5461} 25.7° at 19°; α_{6438} 3.1°, α_{5893} 3.3°, α_{5780} 3.4°, α_{5461} 3.4° ($CHCl_3$, *c* 5.170); data are given for CS_2, C_6H_6 and EtOH, all at room temp. Catalytic reduction of *l*-II gives (+)-phenylethylcarbinol. *l*-II and Ac_2O in C_5H_5N, kept overnight and then warmed to 40° for 1 hr., give *l*-α-*phenylallyl acetate*, b_{16} 111°, α_{6438} 27.2°, α_{5461} 39.93°, α_{5780} 33.39°, α_{4358} 70.5° at 18°, n^{20}_D 1.5092; the *dl*-isomer b_{19} 114°, n^{20}_D 1.5085; heating II and Ac_2O on the steam bath for 3 hrs. gives the same product, showing that no conversion into the isomeric γ-deriv. had taken place. The K deriv. of II and MeI give the *dl-Me ether* (VI), b_{16} 85°, n^{20}_D 1.5105; the isomeric γ-deriv. b_{16} 116°. Slow distn. of III in abs. MeOH for 2 hrs. gives VI; *l*-III gives $C_6H_4(CO_2H)_2$ and VI. *d*-III (11 g.) in 10 cc. MeOH, kept in a closed vessel for 3 weeks at summer room temp., gives 10 g. *d*-III of almost unchanged rotatory power and VI. *l*-III (1 g.) in 20 cc. abs. EtOH showed no alteration in rotatory power after 3 weeks but after 18 months this had decreased 25% and after 33 months to 6% of its original value; the resulting soln. gave 0.3 g. $C_6H_4(CO_2H)_2$ and 0.3 g. of the Et ether of II. Anhyd. HCO_2H and 10 g. of *d*-III react in 2 hrs. to give 5 g. $C_6H_4(CO_2H)_2$, 1.3 g. of partially racemized III and 3 g. γ-phenylallyl formate. In AcOH a 5% soln. of *l*-III changed from α_{5461} 1.96° to 1.34° in 16 days at room temp.; *l*-III (3.2 g.) in glacial AcOH, heated on a steam bath for several hrs., gives 0.6 g. $C_6H_4(CO_2H)_2$, 0.7 cc. cinnamyl acetate and 1.5 g. *l*-III having $[\alpha]_{5461}$ −5.4° (CS_2). A comparison of the reactivities of II with those of I shows that the latter undergo anionotropic changes far more readily than the former. This enhanced reactivity must be ascribed to the influence of the γ-Me group.

C. J. West

Nitrones. V Bellavita. *Atti X° congr. intern. chim.* **3**, 33–8(1939). Extending the reaction of KCN (I) reported in previous papers to *carboxamide derivs.* (II) of aldoniitrones formed by treating aromatic aldehydes with hydroxyurea, B. obtained a new series of ureide derivs., RCH·NCONH$_2$ (III), along with KCNO. Obviously II have an oxidizing action on I. Both the Dumas and Kjeldahl methods for N, however, gave lower results than the calcd. Combustion of III over CuO showed that a certain amt. of HCN was formed, thus explaining the discrepancy in the results. III forms mono- and di-Ac as well as Bz derivs., RCH·NCONHAc, RCH·NCONAc$_2$, RCH·NCONHBz. The benzalureas do not react with $PhCHCl_2$ or $PhCCl_3$ but with $COCl_2$ give compds. of the structure RCH·NCONHCONHCON·CHR. The new compds. reported include PhCH·NCONH$_2$ (liquid); *o*-NO$_2$C$_6$H$_4$CH·NCONH$_2$, m. 103°; *m*-NO$_2$C$_6$H$_4$CH·NCONH$_2$, m. 123.5°; PhCH:CHCH·NCONH$_2$, m. 68–70°; *o*-HOC$_6$H$_4$CH·NCONH$_2$ (liquid); *p*-MeOC$_6$H$_4$CH·NCONH$_2$, m. 67°; H_2C  C_6H_3CH·NCONH$_2$, m. 113.5°. The same compds. may also be obtained by treating the aldehydes with a mixt. of HCNS and NH_2OH. Cf. *C. A.*, **30**, 3119[6].

J. C. Lo Cicero

Ketene in the Friedel-Crafts reaction. I. Direct acetylation of aromatic hydrocarbons with ketene. Jonathan W. Williams and James M. Osborn. *J. Am. Chem Soc.* **61**, 3138–9(1939).—The yield of PhAc from ketene (I) and C_6H_6 may be increased above previously reported values by the following means: use of considerable excess of I; use of I which contains min. amts. of C_2H_4 and CO, operation at 0°; addn. of $AlCl_3$ in small portions with rapid stirring; use of at least 1.5 moles of $AlCl_3$ per mole of C_6H_6; use of an inert diluent, as CS_2. I was passed into a well-stirred mixt. of 100 ml. of C_6H_6 and 300 ml. of CS_2 at 0°; at 15-min. intervals approx. 10-g. portions of $AlCl_3$ were added until 200 g. had been used (5 hrs.); I addn. and stirring were continued for a total of 10 hrs.; the addn. complex was decompd. by pouring onto 1 kg. of cracked ice and 30 ml. of concd. HCl; the yield of PhAc is 32.7%. $C_{10}H_8$ gives 34.8% of Me α-naphthyl ketone (*2,4-dinitrophenylhydrazone*, m. 259°); a small amt. of the β-ketone is formed. Tetralin gives 21.1% of Me β-tetrahydronaphthyl ketone (*2,4-dinitrophenylhydrazone*, m. 236°). Ph_2 gives 23.4% of *p*-PhC$_6$H$_4$Ac.

C. J. West

Splitting of the methyl radical from *o*-methoxyacetophenone and the action of potassium bicarbonate on resacetophenone and its derivatives. Kanzo Okazaki. *J. Pharm. Soc. Japan* **59**, 547–52(in German, 190–3)(1939).—3-Methyl-6-methoxy-7-acetoxycoumarilic acid (0.2 g., prepd. according to Limaye and Sathe, *C. A.* **31**, 2212[2]), and 0.2 g. $PhNH_2$.HI in 1 cc. aniline when heated on the water bath for 7 hrs. at 95° gave 70 mg. 6-hydroxy-7-acetyl-3-methylcoumarone, $C_{21}H_{10}O_3$, m. 112°. Acetylation of 10 g. 4-hydroxybenzyl cyanide (prepd. according to Pschorr, *Ber.* **33**, 170(1900)) gave 4-acetoxybenzyl cyanide (I), $C_{10}H_9O_2N$, m. 49–50°. I (10 g.) and 15 g. $AlCl_3$ were heated at 100–10° for 10 min., cooled, and treated with HCl-ice mix. The ether ext. gave acetyl-4-hydroxyphenylacetonitrile (II), $C_{10}H_9O_2N$, m. 106°, in 75% yield; semicarbazone, decomp. 218–19°. Methylation of II gave 3-acetyl-4-methoxyphenylacetonitrile (III), $C_{11}H_{11}O_2N$, m.

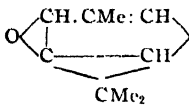
85–6°. **III** (0.5 g.) and 0.57 g. $PhNH_2.HI$ in 1 cc. aniline when heated as described above gave **II**. Methylation of *o*-gallacetophenone (prepd. according to Nencki, *J. prakt. Chem.* [2], **23**, 151(1881)) gave *o*-gallacetophenone tri-Me ether (**IV**), b_5 131°; semicarbazone, decomp. 170°. Splitting of the Me radical from IV as previously described gave a compd. m. 83°, which did not depress the m. p. of the 3,4-di-Me ether of *o*-gallacetophenone. Me *p*-orsellinate di-Me ether (6 g.) in 20 cc. $PhNO_2$, 3 g. AcCl and 7.8 g. $AlCl_3$ when heated for 2 hrs. at 70–90°, gave 2 g. Me 6-methylresacetophenone-3-carboxylate 4-Me ether, $C_{12}H_{14}O_5$, m. 123°, which on methylation gave the di-Me ether (**V**), $C_{18}H_{16}O_5$, m. 92°; semicarbazone, decomp. 215°. An attempt to split off a Me radical from V gave a trace of a compd. which gave a purple-red color with $FeCl_3$. Methylation of 3,6-dimethylresacetophenone (prepd. from β-orcinol) gave 3,6-dimethylresacetophenone di-Me ether (**VI**), b_8 115–18°; semicarbazone, decomp. 206.5°. An attempt to split off a Me radical from VI gave a compd., which gave a purple-red color with $FeCl_3$. Orcinol diacetate gave by the Fries rearrangement 2,6-diacetylorcinol (**VII**), $C_{11}H_{12}O_4$, m. 97°, and a small amt. of isoörcacetophenone (**VIII**). Both VII and VIII gave when treated with $KHCO_3$ *p*-orsellinic acid, $C_8H_8O_5$, decomp. 180°. Resacetophenone (10 g.) and 15 g. $KHCO_3$ when heated in a sealed tube at 190–200° for 5 hrs. gave 5 g. 6-hydroxy-9-methylfluorone, $C_{14}H_{10}O_3$, decomp. 238°. F. I. Nakamura

Chalcones. I. Chalcones derived from resacetophenone and its dimethyl ether. Jagraj Behari Lal. *J. Indian Chem. Soc.* **16**, 296–300(1939).— A mixt. of resacetophenone di-Me ether (**I**) (3.2 g.), 2.5 g. of isovanillin, 10 cc. MeOH (freed from traces of HCHO by distn. over $AgNO_3$) and 10 cc. of 30% KOH in MeOH was heated to boiling and kept at 50–60° for 24 hrs. After diln. with H_2O, the MeOH was boiled off and the reaction mixt. was extd. with Et_2O. The ppt. obtained on acidification with AcOH was washed with H_2O and crystd. from hot alc. to yield 73.6% (3.9 g.) of lemon-yellow prismatic needles of *2,4-dimethoxyphenyl 3-hydroxy-4-methoxystyryl ketone*, $C_{18}H_{18}O_5$, m. 115°. Similar condensations of I with *o*-vanillin (**II**), 5- and 6-methoxysalicylaldehyde and of resacetophenone with II yielded 79.6, 82.2, 82.3 and 63.8% of *ones*: *2,4-dimethoxyphenyl 2-hydroxy-3-methoxystyryl*, 117°; *2,4-dimethoxyphenyl 2-hydroxy-5-methoxystyryl* 129°; *2,4-dimethoxyphenyl 2-hydroxy-6-methoxystyryl*, 116.5°; and *2,4-dihydroxyphenyl 2-hydroxy-3-methoxystyryl*, m. 211°. Attempts were made to det. the optimum conditions for these condensations. C. R. Addinall

Preparation of aminobenzoic acid esters of substituted monoalkylamino alcohols. Samuel D. Goldberg, Wm. F. Ringk and Paul E. Spoerri. *J. Am. Chem. Soc.* **61**, 3562–4(1939); cf. *C. A.* **32**, 5256. —Results of pharmacol. work on previously described compds. suggested the investigation of the properties of a series of esters in which the side chain was limited to 2 C atoms, 1 of which carried 2 alkyl substituents, such as $HOCMe_2CH_2NHR$. A 33% aq. $EtNH_2$ soln. (0.23 mole) and 100 cc. H_2O, treated with 0.18 mole $ClCH_2CMe_2OH$ and shaken in a pressure bottle 24 hrs., gave 58% of *β-ethylamino-α,α-dimethylethanol*, 152.3°, d_4^{19} 0.8777, n_D^{20} 1.4344 (*picrate*, m. 132–3°); *Me analog*, prepd. similarly, b. 142–3°, d_4^{23} 0.8875, n_D^{20} 1.4338 (*picrate*, m. 137–8°); the other analogs were prepd. in 95% EtOH as solvent, refluxing 3–24 hrs.; *Pr*, b. 169–71°, d_4^{19} 0.8646, n_D^{20} 1.4335 (*picrate*, m. 128–9°); *iso-Pr*, b. 158–60°, d_4^{19} 0.8528, n_D^{20} 1.4288 (*picrate*, m. 166–7°); *Bu*, b. 186.7°, d_4^{20} 0.8586, n_D^{20} 1.4362 (*picrate*, m. 121.5–2.5°); *iso-Bu*, b. 180–1°, d_4^{20} 0.8490, n_D^{20} 1.4309 (*picrate*, m. 138.9°); *Am*, b. 205–8°, d_4^{20} 0.8543, n_D^{20} 1.4388 (*picrate*, m. 109–10°); *iso-Am*, b. 202–4°, d_4^{19} 0.8580, n_D^{20} 1.4380 (*picrate*, m. 145–6°). *β-Butylamino-α,α-diethylethanol*, b. 216–20°, d_4^{26} 0.8629, n_D^{20} 1.4433 (*picrate*, m. 127.8°); *iso-Bu analog*, b. 214–16°, d_4^{26} 0.8621, n_D^{20} 1.4410 (*picrate*, m. 130.5–1.5°). These alcs. were reacted with *p*-$O_2NC_6H_4COCl$ in dil. NaOH at a temp. not above 40°; *β-alkylamino-α-dimethylethyl p-nitrobenzoates: Pr* m. 108–9°, *Bu* m. 87–8°, *iso-Bu* m. 130–1°, *Am* m. 107–9°, *iso-Am* m. 112–13°. *β-Isobutylamino-α-diethylethyl p-aminobenzoate*, m. 122–3°, by reduction of the NO_2 ester with Sn and HCl (*sulfate*, m. 131–3°). *β-Alkylamino-α-dimethylethyl p-aminobenzoates: Pr* m. 123–4° (*sulfate*, m. 138–40°, 150–3°); *Bu* m. 116–19° (*sulfate*); *iso-Bu* m. 83.5–4.5° (*sulfate*, m. 142–3°, 158.5–9.5°); *Am* m. 93–5° (*sulfate* (I), m. 163–6°); *iso-Am*, an oil (*sulfate*, m. 131–3°). Subcutaneous toxicity of I (1% concn.): white mice M. L. D. 45 mg./kg., guinea pigs 35–40; intravenous toxicity of I for white mice (1% concn.): 10–15 mg./kg., dogs, 20 mg./kg. I has interesting anesthetic properties, some of which are discussed. The other aminobenzoates were too toxic for injection purposes. C. J. West

Preparation and asymmetric reduction of β-methylcinnamic acid. David Lipkin and T. D. Stewart. *J. Am. Chem. Soc.* **61**, 3295–6(1939).—Complete details are given for a procedure for the Reformatsky condensation of aromatic ketones and $BrCH_2CO_2Et$ leading to max. yields and applicable to any scale of operation and applied to the prepn. of β-methyl-(I) and β-(α-naphthyl)cinnamic acids (**II**). Catalytic reduction of the hydrocinchonine salt of I in abs. EtOH gives a β-phenylbutyric acid with $[\alpha]^{20}_{5461}$ 4.5°, corresponding to about 8–9% of asym. synthesis; the PtO_2 catalyst was 48 days old and the H pressure 3 atm.; in another prepn. with a catalyst 24 days old and a H pressure of 1 atm. the acid had $[\alpha]^{20}_{5461}$ 0.64°. Reduction of the salt of II in EtOH gives an acid with $[\alpha]^{20}_{5461}$ −0.5° ($CHCl_3$). The results indicate that adsorption of these polar substances has not prevented the mol. inductions responsible for the specificity. C. J. West

Asymmetric reduction of β-methylcinnamic acid by *d*-glucose in the presence of Raney nickel. T. D. Stewart and David Lipkin. *J. Am. Chem. Soc.* **61**, 3297–300 (1939).—The reduction of the β-methylcinnamate ion by *d*-glucose in alk. soln., catalyzed by Raney Ni, has been studied with variations in amt. of catalyst, temp., order of mixing, method of prepn. of catalyst and relative concn. of solutes. The optical activity in C_6H_6 of the resulting β-phenylbutyric acid varied from $[\alpha]_{5461}$ 0.31 to −0.42°, corresponding to about 0.5% asym. synthesis. The specificity changed with each variable and a tentative explanation of all of the variations has been presented based upon a simple hypothesis of relative rates of adsorption. Attention is called to the analogous behavior of enzyme-catalyzed reactions. C. J. West



Constituents of Nephromopsis stracheyi f. ectocarpisma Hue. III. Mitizo Asano and Masami Taniguti. *J. Pharm. Soc. Japan* **59**, 607–9(in German, 216)(1939); cf. *C. A.* **33**, 8593⁴.—A mixt. of nephromopsinic and *l*-lichesterinic acid (cf. *C. A.* **29**, 5072⁸) (2 g.) when treated chromatographically gave *l*-protolichesterinic acid, $C_{19}H_{32}O_4$, m. 103–6°, $[\alpha]_D^{19}$ − 12.4° (in $CHCl_3$), which did not depress the m. p. of the *l*-protolichesterinic acid (m. 103–5.5°) of *Cetraria tenuifolia*. The pyrazoline deriv., $C_{21}H_{36}O_4N_2$, m. 60–1°, $[\alpha]_D^{15}$ −288.2°. F. I. N.

The constituents of Catalpa ovata G. Don. Minoru Hiramoto and Kazue Watanabe. *J. Pharm. Soc. Japan* **59**, 261–4(1939)(in English).—The authors have isolated from the bark of the root of *Catalpa ovata* isoferulic acid (I) and sitosterol (II), from the leaves *p*-coumaric acid (III), and from the bark of the trunk *p*-coumaric and ferulic acids (IV). A phenolic coloring matter present in the bark of the root which gave a red soln. with NaOH appeared to be a substance belonging to the anthraquinone series, but it has not been crystd. *Exptl.*: *Isolation of* I.—About 5.7 g. of the bark of the root was boiled to destroy the enzymes and filtered to obtain the aq. ext. The residue was extd. with MeOH. The ext. was evapd. and the residue was combined with the aq. ext. and extd. with ether. The aq. layer was used for the extn. of the glucoside. The ether soln. was shaken with 5% Na_2CO_3 and 1% KOH soln. The Na_2CO_3 ext. (*A*) and KOH ext. (*B*) were separately acidified and extd. with ether. The ether ext. of the Na_2CO_3 ext. (*A*) was evapd. and the residue was recrystd. from hot H_2O; colorless needles m. 228° (decompn.); yield 0.1 g. This was identified as I by mixed m. p. with the synthetic compd. and by elementary analysis. The synthesis of I was accomplished by heating protocatechualdehyde, malonic acid and glacial AcOH or by

heating caffeic acid and MeI in the presence of KOH in sealed tube. The KOH ext. (*B*) on being made acidic with HCl gave a yellow ppt., but it has not been obtained in cryst. form. *Isolation of* **II.**—The ether soln. after extn. with Na_2CO_3 and KOH gave a residue on evapn. This was extd. with petr. ether and then with 95% alc. From the alc. soln. crystals, m. 137°, were obtained. The Liebermann reaction was pos. and the alc. soln. gave a ppt. with digitonin. Acetate, m. 114°. *Isolation of* **III.**—About 0.8 g. of the leaves was extd. with boiling $NaHCO_3$ soln. The ext. was made acidic with 10% HCl and then extd. with ether. After evapg. off the solvent the residue was recrystd. from hot water; needles, m. 202–3°; yield 0.15 g. This was found to be **III** by mixed m. p. and elementary analysis. About 3 kg. of the bark of the trunk was extd. with MeOH. The ext. was evapd. and the residual fluid was extd. with ether. The ether ext. was treated in the same manner as in the case of the leaves to isolate the compd. **III.** Yield 0.1 g. The aq. layer remaining after the extn. with ether was heated with 10% HCl, extd. with ether. The ether soln. was shaken with $NaHCO_3$ soln. and the ether soln. was again made acidic. After evapg. the solvent the residue was recrystd. from hot water. Colorless needles, m. 171°, which were found to be identical with synthetic **IV.**

Nao Uyei

***l*-Δ³-Carene 5,6-epoxide, a constituent of the oil from Zieria smithii.** A. R. Penfold, G. R. Ramage and J. L. Simonsen. *J. Chem. Soc.* **1939**, 1496–504.—In study of the constituents of the essential oil from *Zieria smithii*, the fraction b_{17} 88–90° is shown to contain *l*-Δ³-*carene 5,6-epoxide*

(**I**), b_{14} 83–5°, d_{25}^{25} 0.9454, n_D^{25} 1.4729, $[\alpha]_{5461}$ −88°, $[R_L]_D$ 44.63 (calcd. 43.63). The oil also contains a very small quantity of linalool (*xenylurethan*, m. 83–5°) and of an *alc.*, $C_{10}H_{14}O$, whose *3,5-dinitrobenzoate* m. 119°. I and O_3 in AcOMe at 0° give small quantities of HCHO and Me_2CO and, after oxidation with $KMnO_4$ at 0°, *cis*-homocaronic acid (**II**), m. 135 6° (*di-p-phenylphenacyl ester*, m. 147 9°; 5 cc. of I give 5.5 g. of the Me ester of **II**); some *cis*-caronic acid is also probably formed. Digestion of I with aq. KOH (2.8 g. KOH in 100 cc. H_2O) for 24 hrs. or heating I with H_2O at 150° for 3 hrs. gives geranic acid; I with EtOH-KOH at 24° for 14 days gives a small yield of cyclogeranic acid. I in AcOH, satd. with HCl at 0°, gives *dl-1,8-dichloro-p-menthan-3-one*, decomps. 72° and on keeping; the *di-Br analog* (**III**) decomps. 74° and is extremely unstable. Hydrogenation with Pd-norite in EtOH at 60° is complete in 10 hrs., giving *dl*-menthone (*2,4-diphenylhydrazone*, yellow leaflets or needles, m. 141–2°). Heating **III** in AcOH with AcONa at 140° for 2 hrs. gives Δ¹·⁴⁽⁸⁾-*p-menthadien-3-one* (**IV**), CH:CMe.CH_2.CH_2.C(:CMe_2).CO, b_4 120 2°, d_{25}^{25} 0.9683, n_D^{25} 1.5190, $[\alpha]_{5461}$ −0.1°, $[R_L]_D$ 46.66 (calcd. 45.26); *2,4-dinitrophenylhydrazone*, red needles, m. 187° (from AcOEt-EtOH), or red leaflets, m. 125–7° (from MeOH, the more sol. form). With HBr **IV** gives **III.** **IV** with O_3 in AcOMe gives Me_2CO, levulinic acid (**VA**), an oil yielding a *semicarbazone*, $C_9H_9O_3N$, decomps. 232–3°, and *2-methyl-1-butene-1,4-dicarboxylic acid* (**V**), HO_2CCH:CMe-$CH_2CH_2CO_2H$, m. 121–2°; **V** is unstable to alk. $KMnO_4$, is reduced by Na in EtOH to β-methyladipic acid (**VB**) and with O_3 gives **VA.** **V** is possibly a mixt. of cis and trans isomers, for evapn. of an aq. soln. of the NH_4 salt gives a salt sparingly sol. in EtOH, the acid of which m. 140–1° and may be the Δ²-isomer, for it is reduced to **VB** (*di-p-phenylphenacyl ester*, m. 124–5°). The acid from the sol. NH_4 salt is an oil, catalytic reduction of which gives 60% of the lactone of β-hydroxy-β-methylbutane-α,δ-dicarboxylic acid (?). Heating 3 g. of I at 160–5° for 10 min. gives 3 g. of an oil, b_{13} 95–140°; this is yellow and becomes sage-green on exposure to the air; with Brady's reagent it gives a deep-red solid, m. 203°; the *2,4-dinitrophenylhydrazone*, $C_{16}H_{18}O_4N_4$, purple, m. 218–20°; the *semicarbazone*, $C_{11}H_{17}ON_3$, decomps. 221–2°, and the β-*isomer* decomps. 183–5°; these are sepd. by crystn. from MeOH and EtOH; the yields are small; most of the product could not be sepd. and m. 150–70° and turns reddish brown in the air; all fractions are phototropic. I and aq 2,4-$(O_2N)_2C_6H_3NHNH_2.H_2SO_4$, kept in the cold for 5 days, give a *2,4-dinitrophenylhydrazone* (**VI**), light yellow, m. 145–7°; with an EtOH soln. (8 days) there results 3 *2,4-dinitrophenylhydrazones* (**VII**), garnet, m. 192–3°, and orange (**VIII**), m. 165–6°, as well as **VI.** I and $H_2NNHCONH_2$.AcOH in MeOH (5 days) give a *semicarbazone*, $C_{11}H_{17}ON_3$ (**IX**), m. 192·4°, $[\alpha]_{5461}$ −70° (C_5H_5N, *c* 3.46), and a fraction m. 199°; reduction gives a mixt. from which a *semicarbazone*, $C_{11}H_{21}ON_3$, m. 212°, was isolated. **IX** and 2,4-$(O_2N)_2C_6H_3NHNH_2$ in EtOH-H_2SO_4 for 10 days give a mixt. of **VII** and **VIII.** Hydrolysis of the mixed semicarbazones with $C_6H_4(CO)_2O$ gives a poor yield of a mixt. of ketones; 1 *ketone*, $C_7H_{10}O$, b_{15} 87°, d_{25}^{25} 0.9385, n_D^{25} 1.4712, $[\alpha]_{5461}$ 26.3° (*2,4-dinitrophenylhydrazone*, brick-red, m. 176·7°); the 2nd *ketone*, b_{13} 127–30°, d_{25}^{25} 0.9851, n_D^{25} 1.5029, $[\alpha]_{5461}$ 6.52°, contains some **IV.** C. J. West

A new method of resolving a racemic compound. Geo. M. Henderson and H. Gordon Rule. *J. Chem. Soc.* **1939**, 1568–73.—Complete resolution of *dl-p*-phenylenebis-(iminocamphor) was effected by an adsorption method. A dil. soln. in light petroleum with 12 or 25% C_6H_6 is passed through an adsorption tube packed with *d*-glucose till the pale yellow adsorbed layer occupies ¼ of the tube, then the solvent is passed through the column to expand to the full column. The *d*-form is adsorbed more strongly than the *l*-form so that the upper adsorbate of the tube is the *d*-, the lower adsorbate the *l*-form. Washing the glucose with $CHCl_3$, followed by careful drying, increases its adsorption capacity. The adsorbed *d*- and *l*-forms are recovered by extn. with warm $CHCl_3$. A. Fleischer

ω-Camphor series. I. Synthesis of 2-ketoapocamphane-1-acetic acid. Torsten Hasselstrom and Burt L. Hampton. *J. Am. Chem. Soc.* **61**, 3445–8(1939). —ω-Benzoylborneol oxime (35 g.) in 300 cc. Et_2O, treated with 77 g. PCl_5 during 1 hr. at 20–30°, the product washed with H_2O and distd. with steam, gives 0.5 g. PhCN; the residue from the steam distn., crystd. from EtOH, gives 28.2% of *2-hydroxyapocamphane-1-acetanilide* (**I**), m. 176.5 7.5° (m. ps. cor.), and 17 g. of an oily residue; refluxing this with 10% EtOH-KOH for 3 hrs., pouring into ice water, extn. with Et_2O and crystn. from hexane give 10.1% of *camphenecarboxanilide* (**II**), m. 154.5–5.5°; the aq. alk. soln. gives 1.2 g. of **III.** Refluxing 4.5 g. of **I** with 160 cc of 20% EtOH-KOH for 6 hrs. gives 60% of the *2-hydroxyapocamphane-1-acetic lactone* (**III**), m. 201.5 2.5°. Oxidation of **III** with alk. $KMnO_4$ (refluxing 15 min.) yields 84.4% of *2-keto-1-apocamphane-1-acetic acid*, m. 92–3°; *semicarbazone* (**IV**), m. 199 200°. Wolff-Kishner reduction of **IV** gives 83.2% of *apocamphene-1-acetic acid*, m. 77–8°. **II** is a secondary product apparently formed by way of the Meerwein-Wagner retropinacolone rearrangement from the intermediate 2-chloroapocamphane-1-acetanilide; treating 1 g. **I** in 200 cc. Et_2O with 1.6 g. PCl_5 gives 66% of **II.** Hydrolysis of **II** with EtOH-KOH gives 23% of camphenecarboxylic acid (**V**), m. 126. Alk. $KMnO_4$ oxidizes **II** or **V** to camphenilone. C. J. W.

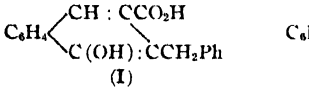
Preparation of camphor by the interaction of pinene hydrochloride with hexamethylenetetramine. P. P. Shorygin, V. N. Belov and S. G. Gurevich. *Wiss. Werke moskau. mendelejeff. chem.-tech. Inst.* **1938**, No. 3–4, 121–3, *Khim. Referat. Zhur.* 2, No. 1, 95(1939).—No camphor was formed in an aq.-alc. medium from the interaction either under atm. pressures or under high pressures. Neg. results were also obtained when EtOH was replaced with iso-AmOH. On heating the hydrochloride of pinene with hexamethylenetetramine in iso-AmOH under pressure some camphor was obtained (together with the other products of the reaction) in amts. of 2% of the theoretical yield.

W. R. Henn

Bitolyl series. VIII. A. Angeletti. *Atti X° congr. intern. chim.* 3, 26–31(1939); cf. *C. A.* **34**, 4068.—*2-*

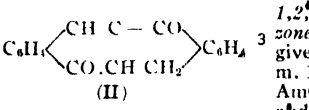
Chloro-2'-amino-6,6'-bitolyl (I) was prepd. according to directions given previously (cf. *C. A.* **26**, 4809). I (10 g.) in 500 cc. 6% HCl was diazotized at 0–4° with 3.2 g. $NaNO_2$ (II) in 30 cc. H_2O. The soln. was filtered and the ppt. washed with H_2O and the filtrate heated to 90°. The product obtained was dissolved in ether and washed thoroughly with dil. NaOH. After drying the ether soln. with solid NaOH and removing the ether, the oil was steam-distd., giving *2,2'-dichloro-6,6'-bitolyl* (III), m. 119°. III was also prepd. from I by the Sandmeyer reaction, from which its identity was confirmed. Similarly *2,2'-dibromo-6,6'-bitolyl* (IV), m. 109–10°, was prepd. from *2-bromo-2'-amino-6,6'-bitolyl*. The yields of both III and IV were quite high. To 10 g. I in 50 cc. H_2O was added 50 cc. H_2SO_4 (1:2) and then 100 cc. H_2O. The soln. was diazotized as usual with 3.2 g. II in 30 cc. H_2O, filtered and warmed to 80°. The product was dissolved with dil. NaOH, then repptd. with HCl, steam-distd. and finally recrystd from 70-proof EtOH. *2-Chloro-2'-hydroxy-6,6'-bitolyl* (4.5 g.), m. 65–6°, was thus obtained. The corresponding Br and I compds., m. 91–2° and 58°, resp., were similarly obtained. J. C. Lo Cicero

Rearrangement in zinc dust distillation. Arthur Lüttringhaus and Grete v. Saäf. *Ber.* **72B**, 2026–8(1939).—In a study of the action of PhNa on aromatic ethers (*Ann.* in press) there was obtained *2,6-diphenylphenol* (I) from *o*-PhC_6H_4OPh (II) and also, in smaller yield, from Ph_2O. In the latter case the reaction was found to proceed through II. The structure of I was proved by the synthesis of I from 2,6,4-$Ph_2(O_2N)C_6H_2OH$ through the amino and diazonium compds. It was also shown that I is produced by intramol. rearrangement from the Na deriv. of 6,2-$NaPhC_6H_3OPh$ (III), of II, and that in the exchange of Na between II and PhNa the Na compd. *o*-(*o*-PhC_6H_4O)-C_6H_4Na (IV), isomeric with III, is formed. By an intramol. rearrangement analogous to that mentioned above, IV should give *o*-(*o*-PhC_6H_4)C_6H_4OH (V), but only 1 product of the compn. $C_{18}H_{14}O$ was obtained. It had been attempted to decide between structures I and V for this product by reducing it to the hydrocarbon by distn. with Zn dust. This, however, gave neither *m*- nor *o*-$C_6H_4Ph_2$ but a cryst. compd. (VI), m. 207°, since shown to be *p*-$C_6H_4Ph_2$ (*p,p'*-dintro deriv., m. 273°). Application to I of the Clar "Zn dust fusion" method (*C. A.* **34**, 947) with $ZnCl_2$ contg. varying (small) amts. of water, at various temps. (280–340°), with different kinds of Zn dust, likewise gave VI. There can be no doubt, therefore, that I undergoes rearrangement on distn. with Zn dust, and hence caution must be used in applying the results of such distns to the detn. of structure. C. A. R.



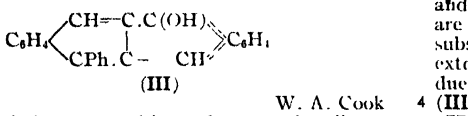
Degradation of 1,8-diphenyloctatetraene to 7-phenylheptatrien-1-al. P. Karrer and H. Obst. *Helv. Chim. Acta* **22**, 1191–2(1939).—1,8-Diphenyloctatetraene in 100-mg. portions in 40 cc. $CHCl_3$ was shaken in a stoppered bottle for 1.5 hr. with 50 cc. $KMnO_4$ soln. (5 g. $KMnO_4$ in 1000 cc. 0.5 *N* H_2SO_4) till a total of 6 g. (60 portions) was worked up. After filtering off the MnO_2, the $CHCl_3$ was concd., giving a dark red-brown oil which upon extg. 4 times with petr. ether and 5 times with ligroin, concg. each ext. and distg. under reduced pressure gave, resp., BzH and 340 mg. 7-phenylheptatrienal as a yellow sublimate, m. 112.5–13°, and yellow crystals upon 2 crystns. from ligroin (270 mg.); *oxime*, dark yellow lustrous flakes, m. 186–7°. The previously reported prepns. (m. 96°, Engelberg, *Diss. Berlin* **1914**; liquid, Vorländer, *C. A.* **23**, 3687; m. 94°, Kuhn and Winterstein, *C. A.* **22**, 1767) were either not uniform or stereoisomers of the present form. John F. Lontz

1,2-Diacylethylene glycols. Reynold C. Fuson, C. H. McBurney and W. E. Holland. *J. Am. Chem. Soc.* **61**, 3246–9(1939); cf. *C. A.* **28**, 2674⁴.—Previously it was shown that mesitylglyoxal reacts with Mg and MgI_2 to give 1,2-dimesitoylethylene glycol (I). It is now shown that *tert*-butyl-, phenyl- (**IA**), 2,4,6-triethylphenylglyoxal (II), *3,5-dibromomesityl-* (**III**) and *isodurylglyoxal* (IV) behave in the same manner. Refluxing 14.5 g. of 3,5-dibromoacetomesitylene with 5.1 g. of SeO_2 in 100 cc. wet dioxane for 4 hrs. gives 41.5% of **III**, b_4 157°; *hydrate*, m. 100–2°; *semicarbazone*, m. 238–41°; *phenylhydrazone*, m. 183–4.5°. Heating II with 10% NaOH gives *3,5-dibromomesityleneglycolic acid*, m. 184.5°. IV, b_3 123–7°, results in 72% yield from acetoisodurene; *hydrate*, m. 86–7°; *semicarbazone*, m. 207–8°; *phenylhydrazone*, m. 118–19°; isodurylglycolic acid, m. 171.5–2° (Claus and Foecking, *Ber.* **20**, 3097(1887) give 156°). II (8.8 g.), added to 7 g. I and 2.5 Mg in C_6H_6-Et_2O, gives 42% of *1,2-di(2,4,6-triethylbenzoyl)ethylene glycol*, m. 104–5° (cor.); *3,5-dibromomesitoyl analog*, m. 229–32° (27%); *2,3,4,6-tetramethylbenzoyl analog*, m. 160–1° (37%). **IA** gives 2 forms of *1,2-dibenzoylethylene glycol* (V); from 19 g. of the reaction mixt. Et_2O exts. all but 3 g. which, crystd. from EtOH, m. 126–7.5° (cor.) (*diacetate*, m. 168–9° (cor.)); the Et_2O mother liquor gives 2 g. of an *isomer*, m. 118–19° (cor.). The yield of V depends on the time of reaction and on the Et_2O-C_6H_6 ratio of the solvent; with Et_2O:C_6H_6 in 1:2 ratio, the yield is only 2%; with a ratio of 2:3 the yield is 55%. Mesityl Ph diketone gives 2,4,6-trimethylbenzoin. I is dehydrated by $(CO_2H)_2$ or H_2SO_4, giving 1,4-dimesityl-1,3,4-butanetrione enol (VI) (*C. A.* **32**, 3370⁴); I, H_2SO_4, $MgSO_4$ and Me_2CO give the *acetone complex* of I, m. 117–18° (cor.). Oxidation of I with $CuSO_4$ in C_5H_5N gives dimesityl diketone; SeO_2 gives dimesityl triketone. $PhNHNH_2$ and I give a *compd.*, $C_{28}H_{28}O_2N_2$, pale yellow, m. 128–9°. Refluxing I with BzCl for 6 hrs. gives the benzoate of VI. Treatment of I with 4 moles EtMgBr, followed by 4 moles of AcCl, gives 1,2-dimesitoylformoin. I with Ac_2O and AcONa gives an intractable oil. C. J. West



Reaction between 2,3-dimethyl-1,4-naphthoquinone and phenylmagnesium bromide. II. H. Marjorie Crawford. *J. Am. Chem. Soc.* **61**, 3310–14(1939); cf. *C. A.* **29**, 7970³.—Further details are given of the prepn. of the 2 diaddn. compds., 1,4-dihydroxy-2,3-dimethyl-1,4-diphenyldihydronaphthalene (I), m. 203–4°, and 1-oxo-2,3-dimethyl-2,4-diphenyldihydronaphthalene (II), m. 124°; II is obtained in a quant. yield by dehydration of I. Oxidation of I gives *o*-$C_6H_3Bz_2$ and II gives PhAc and *o*-$BzC_6H_4CO_2H$; II and PhMgBr give *1-hydroxy-2,3-dimethyl-1,2,4-triphenyldihydronaphthalene* (III), m. 164–74°. *3-Methyl-2-methylene-1,1,4-triphenyldihydronaphthalene* (IV), m. 189–90°, results by dehydration of III or IX (e. g., with $ZnCl_2$ and HCl in C_6H_6); addn. of MeMgI to V and decompn. of the reaction mixt. with HCl gives 76% of IV; a practically quant. yield of IV results by addn. of PhMgBr to VIII and decompn. after 1 hr. with HCl. IV decolorizes Br in CCl_4 rapidly but not $KMnO_4$ in Me_2CO at room temp.; $K_2Cr_2O_7$ in AcOH gives a little BzOH and a neutral oil; O_3 gives V and sometimes also VI. *2-Oxo-3-methyl-1,1,4-triphenyldihydronaphthalene* (V), m. 228°, results by the action of O_3 upon IV or IX; it is unchanged by fusion with KOH or boiling with $K_2Cr_2O_7$ in AcOH for 3 hrs. and does not form a semicarbazone; 1 g. with O_3 in CCl_4 gives 0.6 g. diphenyl(*o*-benzoylphenyl)acetic acid (VI), decomps. 218°; *Me ester*, m. 192–3°. 1,4-Dihydroxy-2,3-dimethyl-1,2-diphenyldihydronaphthalene (VII), m. 208–9° (cf. part I), contains 2 active H atoms; the most interesting reaction of VII is the loss of a mol. of H_2O to give *4-oxo-2,3-dimethyl-1,1-diphenyldihydronaphthalene* (VIII), m. 183°, which occurs on heating at 100° with PBr_3 in $CHBr_3$, heating in C_6H_6 with $ZnCl_2$ and HCl or with I in AcOH; VIII is very inert; reduction with Zn and AcOH (boiling 4 hrs.) appears to give a dihydro deriv., $C_{24}H_{22}O$, m. 142–3°, and a hydrocarbon, m. 176–7°. VIII with PhLi or PhMgBr gives IV; if the Grignard compd. is carefully decompd. after 20 min. with NH_4Cl and H_2O there results 90% of *4-hydroxy-2,3-dimethyl-1,1,4-triphenyldihydronaphthalene* (IX), m. 154°. Oxidation of IV gives small amts. of the hydrocarbon $C_{30}H_{24}$, m. 235°; heating IV with AcOH or I in AcOH did not give the higher-melting isomer. C. J. West

Cyclization of benzylidenebenzylsuccinic acid. E. Bergmann and A. Weizmann. *Compt. rend.* **209**, 539–40 (1939).—By distn. under atm. pressure of the crude condensation product, $C_{18}H_{16}O_4$ (I), from Me benzylsuccinate and BzH, a substance believed to be 2-benzyl-1-hydroxy-3-naphthalenecarboxylic acid, $C_{18}H_{14}O_3$, or an isomer was



isolated; it $b_{0.02}$ 184–8°, colorless prisms, m. 65–8° (from a C_6H_6-petr. ether mixt.). Apparently the distn. is accompanied by an unilateral cyclization. Treatment of I with glacial AcOH yields pure benzylidenebenzylsuccinic acid which, when heated with concd. H_2SO_4 at 70° for 1 hr. (1 g. I and 100 g. H_2SO_4) undergoes a bilateral cyclization. Dilu. of the reaction mixt. with ice water yields a compd., $C_{18}H_{12}O_2$ (II), crystg. from xylene in deep-red needles, m. 265°. II and 10 mols. of PhLi react through addn. of 1 mol. PhLi and loss of 1 mol. H_2O, with the formation of $C_{34}H_{16}O$ (III), m. 255°, citron-yellow prisms from AcOBu and deep red in the liquid state. Its properties are in accord with its suggested formula. Evidently the PhLi reacts on the satd. ketonic group, enolizing the other ketone group simultaneously and creating an entirely aromatic molecule.

Reaction of bromine with anthracene in dioxane. Charles C. Price and Clay Weaver. *J. Am. Chem. Soc.* **61**, 3360-1(1939).—Unless moisture is excluded rigorously the reaction of Br with anthracene in dioxane leads to the formation of 9-bromoanthrone and anthraquinone, as well as the normal product, 9,10-dibromoanthracene. This behavior eliminates the evidence for the ionic mechanism suggested by Price and Thorpe (*C. A.* **33**, 1273[7]) for the cis-trans isomerization of di-Et maleate in the presence of Br and anthracene and the alternate atomic-free radical mechanism is therefore to be preferred. C. J. West

Conjugation of amino acids with isocyanates of the anthracene and 1,2-benzanthracene series. Louis F. Fieser and Hugh J. Creech. *J. Am. Chem. Soc.* **61**, 3502-6 (1939).— β-Aminoanthracene and $COCl_2$ in PhMe-C_6H_6 give a ppt. of the amine-HCl; refluxing 0.5 hr. gives 70% of *β-anthryl isocyanate* (I), pale yellow, m. 207.5–8° (m. ps. below 275° cor.). Refluxing I in MeOH gives *Me β-anthrylcarbamate*, pale yellow, m. 231–1.5°; *Et ester*, light yellow, m. 216–16.5°. I and $NH_2CH_2CH_2OH$ in $CHCl_3$ give *β-anthrylcarbamidoethanol*, bright yellow, m. about 350°. I and concd. NH_4OH in dioxane give *β-anthrylurea*, yellow, does not m. at 360°; β-anthramine gives *N,N'-di-β-anthrylurea*, amorphous, does not m. at 340°. Addn. of $NH_2CH_2CO_2H$ at a pH of 8.5 to I in dioxane gives *β-anthrylcarbamidoacetic acid*, yellow, m. about 310° (decompn.); purification is tedious; the analogous *ε-caproic acid*, dull yellow, m. 285–6°. All of the above derivs. result in a nearly quant. (crude) yield. Reduction of 10-nitro-1,2-benzanthracene with $PhNHNH_2$ gives 20% of the 1-NH_2 deriv. (II), but $SnCl_2$ in concd. HCl-AcOH yields 77% of II, which gives 78% of *1,2-benz-10-anthryl isocyanate* (III), m. 144–4.5°; compds. prepd. from III showed marked tendency to sep. in a gelatinous condition. *Me 1,2-benz-10-anthrylcarbamate*, by refluxing III with MeOH for 15 min., m. 227–7.5°; *Et ester*, m. 204–4.5°; $H_2NCH_2CH_2OH$ gives *1,2-benz-10-anthrylcarbamidoethanol*, m. 247–8°; NH_4OH in dioxane gives *1,2-benz-10-anthrylurea*, m. 334–6° (decompn.); the *N,N'-di(1,2-benz-10-anthryl)urea* is amorphous and unmelted at 330°. III in C_5H_5N at room temp. gives a yellow soln. from which a *polymer* quickly seps. as a yellow powder, m. 305–7° (decompn.). *1,2-Benz-10-anthrylcarbamidoacetic acid*, amorphous, light brown, m. 270–5° (decompn.); *Et ester*, from glycine ester, m. 245–5.5° (it could not be hydrolyzed to the acid); *ε-(1,2-benz-10-anthrylcarbamido)caproic acid*, amorphous, m. 265–7°. *1,2,5,6-Dibenz-9-anthrylurea*, m. 260–3° (decompn.); the 9-carbamidoacetic acid, yellow, m. about 300° (decompn.); *ε-(1,2,5,6-dibenz-9-anthrylcarbamido)caproic acid*, m. about 305°. The 9-isocyanate and the 9-amine in C_6H_6 did not form a urea; reaction occurred with $PhNH_2$ but a satisfactory product was not isolated. *N,N'-Di-(9-anthryl)urea*, m. above 360°. *1,2-Benz-3-anthryl isocyanate*, light yellow, m. 163–3.5°; C_5H_5N at 25° gives an amorphous, high-melting polymer. *Me 1,2-benz-3-anthrylcarbamate*, m. 203.5–4°; *Et ester*, m. 211.5–12°. *1,2-Benz-3-anthrylcarbamidoethanol*, m. 343–5°. *1,2-Benz-3-anthrylurea*, m. above 350°; *N,N'-disubstituted urea*, light brown powder, m. above 350°. *1,2-Benz-3-anthrylcarbamidoacetic acid*, pale yellow, m. about 310° (decompn.); the analogous *caproic acid* m. 295–7°.

C. J. West

Reduction of 4-keto-7-hydroxy-1,2,3,4-tetrahydrophenanthrene with sodium and amyl alcohol. Munemaro Miyasaka. *J. Pharm. Soc. Japan* **59**, 648–55(in English, 278–82)(1939).—Boiling of γ-(2-methoxy-6-naphthyl)-butyric acid with P_2O_5 in C_6H_6 gives *4-keto-7-methoxy-1,2,3,4-tetrahydrophenanthrene* (I), m. 56°. *Semicarbazone*, m. 235°. Boiling of I in C_6H_6 with $AlBr_3$ or $AlCl_3$ gives *4-keto-7-hydroxy-1,2,3,4-tetrahydrophenanthrene* (II), m. 117°; *acetate*, m. 105°. II is reduced with Na and iso-AmOH. After addn. of H_2O to the reduction products and removal of iso-AmOH by steam, the neutral substances are extd. with ether. Evapn of the solvent gives an oily substance in small amt. The alk. aq. soln. is acidified and extd. with ether. On evapn. of the ether, a phenolic residue is obtained. Recrystn. from AcOEt gives platelets (III), m. 189°. From the mother liquor crystals (IV), m. 177°, are obtained. Both III and IV gave the empirical formula $C_{14}H_{18}O_2$. Monobenzoate of IV, m. 110°. The mixed m. p. of equal parts of III and IV is 150°, showing the 2 are different substances. M. considers that these are stereoisomeric *4,7-dihydroxy-1,2,3,4,9,10,11,12-octahydrophenanthrenes*, the isomerism being due to the OH group at C atom 1. III should be the trans form, because of its higher m. p., and IV the cis form. It is of interest to note that reduction of II takes place at the B nucleus, giving the aromatic compd. in much greater yield than the alicyclic. Reduction of II in AcOH by H in presence of PtO_2 gives *2-hydroxy-1,2,3,4,5,6,7,8-octahydrophenanthrene*.

Nao Uyei

Synthesis of substances related to the sterols. XXVIII. Robert Robinson and J. M. C. Thompson. *J. Chem. Soc.* **1939**, 1739–42; cf. *C. A.* **34**, 7703. γ-1-Naphthylbutyryl chloride (I) (from 20 g. acid) in 60 cc. Et_2O, slowly added to the Na deriv. from 20 g. Et acetylsuccinate in Et_2O cooled in a freezing mixt., allowed to reach room temp. during 2 hrs., kept overnight and then refluxed 10 hrs., the product (35.5 g.) shaken with KOH in EtOH, the neutral material extd. with Et_2O and the acidic product hydrolyzed by heating with 2 *N* NaOH on the steam bath for 2 hrs., gives after esterifying with CH_2N_2 8.3 g. of *Me ester* (II), $b_{0.4}$ 193–8°, n_D^{15} 1.5685, of *4-keto-7-α-naphthylheptanoic acid*, m. 123–4° (*semicarbazone*, m. about 170° (decompn.)). The action of EtONa on II gives no pseudo-acidic product and dil. mineral acid pptd. sirupy material which could not be crystd.; this is believed to be an indication of failure to obtain the cyclopentane-2,5-dione. The cyclodehydration of this crude material with P_2O_5 in moist C_6H_6 gives 3'-keto-3,4-dihydro-1,2-cyclopentenophenanthrene (*C. A.* **31**, 1420[8]). I and the Na deriv. of Et α-acetylglutarate give *5-keto-8-α-naphthyloctanoic acid*, m. 66–7°; *Me ester* (III), $b_{0.4}$ 200–5°, n_D^{20} 1.5625; *semicarbazone*, m. about 118°; the ester and EtONa, kept at room temp. for 24 hrs. and refluxed 30 min., give *β-1'-naphthylethylcyclohexane-2,6-dione*, m. 199–200°; P_2O_5 in moist C_6H_6 gives 16% of *3-keto-1,2,3,4,5,6-hexahydrochrysene* (IV), m. 154–6°; this also results from III and P_2O_5 in moist C_6H_6; *2,4-dinitrophenylhydrazone*, dark red, m. 284° (decompn.). Details are given of the prepn. of the 9-MeO deriv. of IV (*2,4-dinitrophenylhydrazone*, crimson, m. 284° (decompn.)), previously reported by Chuang, Tien and Huang (*C. A.* **31**, 4674[1]); reduction with Na in EtOH gives *3-hydroxy-10-methoxy*(or *ethoxy*)*-1,2,3,4,5,6,-15,16-octahydrochrysene*, isolated as the *p-nitrobenzoate*, yellow, m. 218–19°; the MeO group may be replaced by EtO in the reaction.

C. J. West

Azetidine derivatives. I. 2,4-Diketo-3-hydroxy-3-arylazetidines. J. L. Riebsomer, Howard Burkett,

Thomas Hodgson and Fred Senour. *J. Am. Chem. Soc.* 61, 3491–3(1939).—$Ph(OH)C(CO_2Et)_2$ (25 g.) and 7.5 g. Na in 80 cc. abs. EtOH, heated to 115–20° and treated with 10 g. $CO(NH_2)_2$, stirred at 115–20° for 5 hrs., 10 g. $CO(NH_2)_2$ again added and the stirring and heating continued for about 11 hrs., the soln. evapd. to dryness, the product dissolved in 100 cc. H_2O, 50 g. ice and 10% HCl added until the soln. is acid, and the soln. extd. with Et_2O, give 17% of *2,4-diketo-3-hydroxy-3-phenylazetidine*, $PhC(OH).CO.NH.CO$, m. 107.5–8°; NH_3 may be bubbled into the mixt. instead of the addn. of $CO(NH_2)_2$, the yield being about 3%. Similarly prepd. were the *p-tolyl deriv.*, m. 131° (9%); the *p-ethylphenyl deriv.*, m. 105–6° (24%); the *2,5-dimethylphenyl deriv.*, m. 135–6° (37%); the *mesityl deriv.*, m. 151–2° (6%); the *p-sec-butylphenyl deriv.*, m. 80–90° (38%). The structure of these compds. follows from their hydrolysis with NaOH to $PhCH(OH)CO_2H$ and its derivs., $Ph(HO)C(CO_2Na)_2$ being assumed as an intermediate. These compds. are inactive as hypnotics when given to rabbits and are toxic in relatively small doses.

C. J. West

β-Phenylfurylethylamine and analogous derivatives of thiophene and pyrrole. Robert Robinson and W. M. Todd *J. Chem. Soc.* **1939**, 1743–7.—On account of the remarkable physiol. effects of histamine it was considered desirable to prep. compds. possessing the ethaneamine chain linked to heterocyclic rings other than iminazole. β-2-(5-Phenylpyrryl)propionic acid (Kehrer and Igler, *Ber.* 35, 2009(1902)) is obtained in 87% yield by heating an intimate mixt. of diketophenylheptanoic acid and $AcONH_4$; refluxing 10 g. of the acid with 4 g. concd. H_2SO_4 in 100 cc. EtOH for 4 hrs. gives 82% of the *Et ester*, pale pink, m. 103°; an excess of $N_2H_4.H_2O$ (refluxing 1 hr.) gives 80% of the *hydrazide* (I), m. 137°. I (7 g.) and 4 g. $NaNO_2$ in 10 cc. H_2O, covered with Et_2O and treated with 30 cc. 2 *N* HCl with stirring and ice cooling, give an Et_2O soln. of the azide; MeOH (removing the Et_2O and refluxing 2 hrs.) gives the methylurethan which, refluxed with satd. $Ba(OH)_2$-MeOH for 36 hrs., gives an unsatisfactory yield of *β-2-(5-phenylpyrryl)ethylamine-HCl*, pale pink, m. 225°. Refluxing 20 g. 4,7-diketo-7-phenylheptanoic acid (II), 15 g. P_2O_5 and 300 cc. C_6H_6 for 2 hrs. gives 88% of *β-2-(5-phenylfuryl)propionic acid*, m. 116°; *Et ester*, b_{2-3} 105–7°, m. 20–1°, n_D^{18} 1.5508; in another expt. a small amt. of the *Et ester* of II is formed, m. 23–5°. *β-2-(5-Phenylfuryl)propionhydrazide*, m. 110°, quant. yield; *Me β-2-(5-phenylfuryl)ethylcarbamate*, m. 59–60°; refluxing with $Ba(OH)_2$-MeOH for 24 hrs. gives 50–60% of *β-2-(5-phenylfuryl)ethylamine-HCl* (IIA), m. 205–6°; *picrate*, orange-yellow, m. 200°; *Bz deriv.*, m. 121°; *Ac deriv.*, m. 72°. *Me 4,7-diketo-7-phenylheptanoate*, b_2 197°, m. 41°, n_D^{18} 1.5180, 88% yield with CH_2N_2; P_2S_5 at 98° (1 hr.) gives about 50% of the *Me ester*, m. 75° (with 0.5 mole H_2O), of *β-2-(5-phenylthienyl)propionic acid*, with 0.5 mole H_2O, m. 148°; the *hydrazide* m. 151° (quant. yield); *Me β-2-(5-phenylthienyl)ethylcarbamate*, m. 100°; hydrolysis with concd. HCl or better with MeOH-$Ba(OH)_2$ gives 50–60% of *β-2-(5-phenylthienyl)ethylamine-HCl*, m. 206°; *picrate*, scarlet, m. 217°; *Bz deriv.*, m. 141°; *Ac deriv.*, m. 128°. Furfuraldehyde and *p*-$MeOC_6H_4Ac$, added to 1% MeOH-MeONa with shaking and cooling and kept at room temp. for 2–3 hrs., give 80–90% of *furfurylidene-p-methoxyacetophenone*, straw-yellow, m. 79°; hot EtOH-HCl gives 50–5% of *4,7-diketo-7-p-methoxyphenylheptanoic acid* (III), m. 119°; *β-2-(5-p-methoxyphenylpyrryl)propionic acid*, m. 170–1°; *Et ester*, m. 103°; *hydrazide*, m. 169°; this could not be converted into the azide because of profound decompn. Refluxing III with P_2O_5 in C_6H_6 for 2 hrs. gives 70–5% of *β-2-(5-p-methoxyphenylfuryl)propionic acid*, m. 141°; *Et ester*, b_2 189–95°, m. 52°; *hydrazide*, m. 136°; *Me β-2-(5-p-methoxyphenylfuryl)ethylcarbamate*, m. 89°; refluxing with MeOH-$Ba(OH)_2$ for 24 hrs. gives an unsatisfactory yield of *β-2-(5-p-methoxyphenylfuryl)ethylamine-HCl*, m. 240°. III and CH_2N_2 give 90% of the *Me ester*, b_3 248°, m. 48°; heating with P_2S_5 at 90–100° for about 1 hr. gives 50–60% of the *Me ester*, m. 94°, of *β-2-(5-p-methoxyphenylthienyl)-propionic acid*, m. 178°; *hydrazide*, m. 165°; *Me β-2-(5-p-methoxyphenylthienyl)ethylcarbamate*, light yellow, m. 112°, 80%; hydrolysis with concd. HCl or better with MeOH-$Ba(OH)_2$ gives 60% of *β-2-(5-p-methoxyphenylthienyl)ethylamine-HCl*, m. 283°; *Ac deriv.*, m. 145°. 4,7-Diketoöctanoic acid (IV) and P_2O_5 in C_6H_6, refluxed 2 hrs., give 50% of *β-2-(5-methylfuryl)propionic acid* (V), m. 54–5°; esterification with EtOH and concd. H_2SO_4 gives 2 fractions b_{2-3} 97°, n_D^{15} 1.457, and b_{2-3} 136°, n_D^{15} 1.445 (75%); the lower fraction is an impure sample of the desired ester but the esterification causes the furyl ring to open, yielding the diketo ester; esterification with 5% EtOH-H_2SO_4 converts IV into a mixt. of its ester and the furyl ester, that of IV predominating. V (10 g.) and CH_2N_2 give 7.8 g. of the *Me ester*, b_{2-3} 83°, n_D^{15} 1.465; the *Me ester* of IV b_4 140°, n_D^{15} 1.4458. Catalytic reduction of IIA with Pd-charcoal in EtOH gives *β-2-(5-phenyltetrahydrofuryl)ethylamine-HCl*, m. 122°. The physiol. properties of these bases are being studied. C. J. W.

Isonitrosopyrroles. IX. Products of the transformation of isonitrosopyrrole. T. Ajello. *Atti X° congr. intern. chim.* 3, 7–14(1939); cf. *C. A.* 32, 4557[7].—In addn. to the black compd. $(C_4H_3N_2O)_x$ (I) reported by Angeli and Cusmano (cf. *C. A.* 12, 1291) there are obtained by the action of acid on isonitrosopyrrole (II) 2 other black compds., $(C_4H_3NO)_x$ (III) and $(C_4H_3NO_2)_x$ (IV), and a white compd. $C_4H_4N_2O_2$ (V), m. 210° (decompn.). IV and V can both be obtained together from I by treating it with mineral acid. V is obtained by extn. with ether while IV comes out as a ppt. Salts of NH_3 are formed simultaneously. III was obtained from II by partially satg. it with CO_2. I does not ppt. out when II is treated directly with H_2SO_4, but IV and V are gradually formed. V can be purified from concd. aq. or alc. solns., is slightly sol in benzene, $CHCl_3$, ether and insol. in petr. ether and ligroin. It becomes brown at 180°, softens at 206–8° and m. 210–12° (decompn.), changing to a slimy carbonaceous mass. In the pure state it does not react with $FeCl_3$, but does give a reddish violet color when impure. It gives no reaction to litmus although acidic in nature, forms an explosive white salt of Ag, does not reduce Fehling soln., is not reduced by Zn and HOAc, does not react with HNO_2, gives a mono-Bz deriv., $(C_4H_3N_2O)$-OBz, m. 245°, and a mono-Me deriv. $(C_4H_3N_2O)OMe$, m. 170°. Oxidized with alk. $KMnO_4$ it gives $H_2C_2O_4$ and CO_2. Dil. and alc. KOH with V yield some NH_3 and a volatile fatty acid. Concd. KOH gives an equiv. amt. of NH_3 and a white unidentified material. Warm, somewhat concd. solns. of mineral acids give the soln. a high reducing power attributed to NH_2OH by Angeli (cf. *Ber.* 29, 1884(1896)), and a compd. m. 287°, corresponding to fumaric acid from mixed m. p., neutralization equiv., reduction to succinic acid by 3% Na-Hg and oxidation to tartaric acid. The structure CH.CH.O.N:CCH:NOH is attributed to V. X. *Ibid.* 15–21.—Isonitrosopyrrole (I) was treated with $NH_2OH.HCl$ (II) and with $NH_2NHCONH_2.HCl$ (III) in order to obtain more information on the structure of the compd. $C_4H_3N_2O_2$ (IV), m. 210°, reported in part IX above. With II a white compd., $C_4H_3N_3O_2$ (V), m. 256°, was obtained. It was of weakly acid nature, giving a Ag salt and a Bz deriv., did not react with $FeCl_3$. It was stable to HOAc and HNO_2 and was not reduced by Zn and acid. A possible structure for V is HON.CHCH$_2$C.N.O.N:CH. It was not possible, however, to obtain the corresponding aldehyde but strong hydrolytic action resulted in the complete destruction of the compd., giving NH_2OH, fumaric acid and NH_3. It was also impossible to obtain V from IV by treating it with II. Following the procedure used in older researches (cf. *C. A.* 31, 6652[2]), A. obtained 2 compds. from the action of III on I: $C_4H_3NO:NNHCONH_2$, m. 230°, and $C_4H_4N_2O$: $NNHCONH_2$ (VII), m. 295°, sepd. by fractional crystn. VII with II gave V as did VI. V with III gave VII. In no case was IV obtained. IV with III gave a mixt. of VI and VII. The above facts apparently exclude the isoxazole structure for IV which was advanced in part IX and seem

to support the views of Cusmano according to which IV would be *maleinimide dioxime*, VI *maleinimide monosemicarbazone* and VII the *semicarbazone* of *maleinimide monoxime*. J. C. Lo Cicero

Isonitrosopyrroles. XII. Transformation of the pyrrole nucleus into the pyrimidinic nucleus. Tommaso Ajello. *Gazz. chim. ital.* **69**, 460–70(1939); cf. preceding abstr. and *C. A.* **34**, 99[1].—In a general discussion it is shown that there is an analogy between the reaction whereby pyrrole (I) is transformed into C_5H_5N derivs. or into its aldehyde and pyrroles are transformed into their corresponding isonitroso derivs. It is further shown that, in view of this analogy, it should be possible to pass from these isonitroso compds. to derivs. of pyridizine and pyrimidine. As a start in this problem, the effects of heat, of HCl and of PCl_5 on α,α',β'-triphenyl-β-isonitrosopyrrole (II) and on α,α'-diphenyl-β-isonitrosopyrrole (III) were studied. When heated above their m. ps., II and III do not decomp. according to the reaction foreseen, but much more profoundly, with formation of NH_3, HCN, BzH, BzOH and brown or red-brown resins when air is present and the same products, except BzOH, in the absence of air. Treatment of suspensions of II and III in $CHCl_3$ form only the corresponding HCl salts. If water is present, II and III are partially transformed into diphenylbenzoylisoxazole and phenylbenzoylisoxazole, resp., the yields of these latter varying directly with the proportion of water. Evidently in this case hydrolysis of the I nucleus takes place, as in earlier expts. (cf. *C. A.* **32**, 4557[7]). Progressive addn. of PCl_5 (10 g.) to an ice-cold suspension of II (5 g.) in $CHCl_3$ (50 cc.) gives a dark red soln., which, allowed to stand closed for 12 hrs., ppts. a mixt. of PCl_5 and a yellow substance which could not be extd. with any anhyd. solvent tried. The reaction mixt. was therefore dild. with Et_2O, chilled, ice and then dil. NH_4OH were added, the Et_2O layer was dried with Na_2SO_4, clarified, evapd. and the residue purified by EtOH or AcOH; this yielded triphenoxypyrimidine (IV), m. 340° (cf. Atkinson, Ingham and Thorpe, *C. A.* **1**, 2128). More IV can be recovered from the aq. layer. In the purification of IV there is sometimes obtained another *compd.* (V), m. 228°, which does not contain Cl and which, boiled with glacial AcOH for 12 hrs., yields IV. The most favorable conditions for the formation of V could not be ascertained. Under the same conditions as with II and PCl_5, III and PCl_5 form diphenoxypyrimidine, m. 286° (cf. 281° of Pinner, *Ber.* **22**, 1626(1889)). The expts. show that there is an analogy between the reaction whereby I forms C_5H_5N derivs. and the transformation of the I nucleus through isonitroso compds. to pyrimidine compds. However, the oximinic structure attributed to isonitrosopyrroles (cf. Angeli and collaborators, *Rend. accad. Lincei* **1899** to **1912**) suggests that the reaction may represent a Beckmann transposition. On the other hand, the variations in the course of the reaction and the fact that at times a product, viz., V, which can be converted into a pyrimidine, is formed suggests that the reaction progresses through the formation of intermediate products, analogous to those in the passage of I to C_5H_5N. C. C. Davis

β-Diazo-α-phenylindole. S. Capuano. *Atti X° congr. intern. chim.* **3**, 73–7(1939); cf. *C. A.* **33**, 3375[1].—To 2 g. *β-diazo-α-phenylindole* (I) in 40 cc. 95-proof EtOH is added a concd. aq. soln. of 4 g. NH_4Cl and the soln. is warmed in a water bath. After the gas has ceased to be evolved, heating is continued for a while, whereupon the soln. is cooled and filtered. By repeated treatment with benzene the hydrazo (II) and azo (III) derivs. are sepd. (II being insol.). II, decompg. 271°, could be converted to III, decompg. 263°, with AmONO. To 4 g. I in 80 cc. alc. are added 40 cc. of 10% KOH, the soln. is warmed, concd. and cooled, ppts. *α-phenylindole* identified from its isonitroso deriv. In both treatments AcH is formed, indicating the oxidizing character of I. J. C. Lo Cicero

The condensation of isatin with phenols. II. Isatin and 8-hydroxyquinoline. Yu. O. Gabel and V. M. Zubarovskii. *Trudy Khar'kov. Gosudarst. Univ.* **3**, 67–71 (1938); *Khim. Referat. Zhur.* **2**, No. 1, 55–6(1939).—For the prepn. of 2-oxo-3,3-bis(8-quinolyloxy)indoline, $C_{26}H_{17}N_3O_3$ (I), 10 g. of isatin and 20 g. of 8-hydroxyquinoline were fused with 3 cc. of $POCl_3$. The product was pulverized and treated with dil. AcOH. The yield was 16 g. of I. It is insol. in water and in ordinary org. solvents, is insol. in bases, sol. in H_2SO_4 and HCl (not too dil.). The structural formula of (I) is $C_6H_4.NH.CO.C(OC_9H_6N)_2$; with Ac_2O it forms an almost colorless product, $C_{28}H_{19}O_4N_3$, [*N*-Ac deriv.] which decomps. above 150°, is sol. in acetone, $CHCl_3$ and acids. W. R. Henn

Synthesis of diphenylene dioxide derivatives. XV. Synthesis of α-oxo(or hydroxy)-β(or γ)-morpholylalkyldiphenylene dioxides. Masao Tomita. *J. Pharm. Soc. Japan* **59**, 538–42(in German, 205–6)(1939); cf. *C. A.* **32**, 7464[1]; **33**, 2898[3].—2,6-Di(β-chloroacetyl)diphenylene dioxide (1 g.) and 5 cc. morpholine when heated on the water bath at 80° gave 0.8 g. 2,6-di(α-oxo-β-morpholylethyl)-diphenylene dioxide (I), $C_{24}H_{28}N_2O_8$, m. 195°; HCl salt, m. above 300°. I (0.5 g.) in 10 cc. alc., 1 cc. water and 20 g. 5% Na-Hg when heated on the water bath for 5 hrs. gave 0.2–0.3 g. 2,6-di(α-hydroxy-β-morpholylethyl)diphenylene dioxide, $C_{24}H_{30}N_2O_8$, m. 202°. 2,6-Di(α-chloropropionyl)diphenylene dioxide (1 g.) and morpholine when treated as before gave 1.2 g. 2,6-di(α-oxo-γ-morpholylpropyl)diphenylene dioxide (II), $C_{26}H_{30}N_2O_8$, m. 176°; HCl salt, m. above 280°. Reduction of II with Na-Hg as before gave 2,6-di(α-hydroxy-γ-morpholylpropyl)diphenylene dioxide, $C_{26}H_{34}N_2O_8$, m. 199°. 2,6-Di(β-chloroacetyl)-3,7-dimethyldiphenylene dioxide (1 g.) and morpholine when treated as before gave 1.2 g. 2,6-di(α-oxo-β-morpholylethyl)-3,7-dimethyldiphenylene dioxide, $C_{26}H_{30}N_2O_8$, m. 171°; HCl salt, m. above 280°. Reduction of the above compd. with Na-Hg gave 2,6-di(α-hydroxy-β-morpholylethyl)-3,7-dimethyldiphenylene dioxide, $C_{26}H_{34}N_2O_8$, m. 242°. In like manner 1 g. 2,6-di(β-bromopropionyl)diphenylene dioxide and 5 cc. morpholine gave 2,6-di(α-oxo-β-morpholylpropyl)diphenylene dioxide, $C_{26}H_{30}N_2O_8$, m. 184°; HCl salt, m. above 280°. Reduction of the above oxo compd. with Na-Hg gave 2,6-di(α-hydroxy-β-morpholylpropyl)diphenylene dioxide, m. 220–32°. F. I. Nakamura

2-(*p*-Aminobenzenesulfonamino)thiazole: a new chemotherapeutic agent. W. A. Lott and Frank H. Bergeim. *J. Am. Chem. Soc.* **61**, 3592–4(1939); cf. Fosbinder and Walter, *C. A.* **33**, 7795[1].—2-(*p*-Aminobenzenesulfonamino)thiazole (I) (F. and W.), m. 202–2.5° (cor.); soly. in EtOH at 26°, 525 mg. per 100 cc.; in H_2O at 26°, 60 mg. per 100 cc., giving pH 6.03 (about twice the soly. of sulfapyridine (II)). The *Na salt* of I m. 264.5–5° (cor.); a 2% soln. has pH 9.57. The *HCl salt* of I m. 193–7°; the soly. in H_2O is less than 2% with pH 1.28; it loses HCl on standing. The potentiometric titration curves for the acidification of 2% soln. of the Na salts of I and II show that I is more strongly acidic than II. The *4-Me deriv.* of I m. 237–8°; the *4-Et deriv.* m. 149.5–50.5° With $CuSO_4$ the Na salt of I gives a purple ppt. and II gives an apple-green ppt.; this is a test to distinguish the 2 drugs. C. J. West

Chromones of the naphthalene series. I. Transformation of *o*-aroyloxyacetoarones into *o*-hydroxydiaroylmethanes. V. V. Virkar and T. S. Wheeler. *J. Chem. Soc* **1939**, 1679–81.—1,2-$HOC_{10}H_6Ac$, α-$C_{10}H_7COCl$ and C_5H_5N, heated 1 hr. at 100°, give *1,1'-naphthoyloxy-2-acetonaphthone* (I), m. 135°; the 2'-isomer (II) m. 113–14°, and *1,3'-methoxy-2'-naphthoyloxy-2-acetonaphthone* (III) m. 119°. Heating 5 g. I and 0.4 g. Na in 35 cc. PhMe for 3 hrs. gives *1-hydroxy-2,1'-dinaphthoylmethane* (IV), yellow, m. 142°; 1 g. IV with 5 cc. Ac_2O and 5 cc. HI (d. 1.7), kept at room temp. for 2 hrs., gives 0.5 g. of *2,1'-naphthyl-7,8-benzochromone* (V), m. 205°. II with Na in PhMe gives *1-hydroxy-di-2-naphthoylmethane*, yellow, m. 164°; HBr in AcOH gives the *2'-isomer* of V, m. 190–1°. III yields *1-hydroxy-3'-methoxy-2,2'-dinaphthoylmethane*, orange, m. 163°; HBr in AcOH yields *2-(3'-methoxy-2'-naphthyl)-7,8-benzochromone*, m. 204–5°; refluxing the latter with HI in Ac_2O for 24 hrs. gives the *3'-HO deriv.*, greenish yellow, m. above 300° (*Ac deriv.*, yellow, m. 180–

1°). *o*-$BzOC_6H_4Ac$ with Na in Et_2O, kept overnight and then shaken 5 hrs., gives *o*-$HOC_6H_4COCH_2Bz$ which with HBr in AcOH gives flavone. 1-Acetoxy-2-acetonaphthone and Na in PhMe, refluxed 3 hrs., give 1-hydroxy-2-naphthoylacetone, yellow, m. 117–18°; HI in AcOH gives 2-methyl-7,8-benzochromone, m. 178–9°. **II. Synthesis of linear naphthoflavone (6,7-benzoflavone).** *Ibid.* 1681-3.—PhAc and 2,3-$MeOC_{10}H_6CO_2Me$ with Na in Et_2O, shaken 3 hrs. and kept overnight, give *benzoyl-2-methoxy-3-naphthoylmethane* (I), yellow, m. 98°. *o*-$MeOC_6H_4Ac$ gives the *o-anisoyl analog* (II) of I, yellow, m. 120–2°. *3-Methoxydi-2-naphthoylmethane*, yellow, m. 160°; *di(1-methoxy-2-naphthoyl)methane*, yellow, m. 122°; *2,3'-dimethoxy-1,2'-dinaphthoylmethane* (IIA), yellow, m. 163°. II and Br in $CHCl_3$ give a *Br deriv.*, m. 152°; the Br could not be replaced by Ac with AcONa in AcOH. Heating 0.5 g. I in 5 cc. Ac_2O and HI for 1 hr. gives 0.25 g. of *6,7-benzoflavone* (III), m. 171–2°; HBr in AcOH also gives III. Heating III with EtONa-EtOH under a reflux for 4 hrs. gives 2-hydroxy-3-acetonaphthone (*C. A.* **31**, 9064) and 2,3-$HOC_{10}H_6CO_2H$. II gives the *2'-MeO deriv.* of III, m. 165°; *2'-HO deriv.* of III, greenish yellow, m. 256–7°; *2'-AcO deriv.*, m. 136–8°; EtONa-EtOH decomps the MeO deriv. into the same products as III. *2,2'-Naphthyl-6,7-benzochromone*, yellow, m. 193°. *2-(1'-Methoxy-2'-naphthyl)-7,8-benzochromone*, m. 151–2°; the *1'-HO deriv.*, greenish yellow, m. above 280° (*Ac deriv.*, m. 171°). IIA and III in Ac_2O at 100° for 15 min. or HBr in AcOH for 12 hrs. at room temp. give *2-(3'-methoxy-2'-naphthyl)-5,6-benzochromone* or *2-(2'-methoxy-1'-naphthyl)-6,7-benzochromone* (the latter is preferred), m. 94°, the *HO deriv.*, greenish yellow, m. 283–5° (*Ac deriv.*, m. 148–50°). C. J. West

Catalytic reduction of chromone and coumarone derivatives. F. Pribinger and H. Schmid. *Monatsh.* **72**, 427–31. *Sitzber. Akad. Wiss. Wien. Math.-naturw. Klasse, Abt IIb*, **148**, 125–9(1939).—3-Methyl-6-hydroxycoumarone (I), m. 106°, is catalytically reduced in 3 hrs. to 3-methyl-6-hydroxycoumaran, $b_{0.6}$ 80–90° (bath temp.), m. 60° (Karrer and Widmer, *C. A.* **14**, 1299, gives 96°). I and PhCN give 3-methyl-5-benzoyl-6-hydroxycoumarone, m. 171.5° (K. and W. give 159° for a compd. they believed to be the coumaran); I could not be reduced by Na and EtOH as stated by K. and W. 7-Methoxychromone (II) is reduced by Pd and H to 7-methoxychroman (III), an oil; the *7-HO deriv.* m. 70–2°. Reduction of the 2-Ph deriv. of II gives the corresponding *chroman*, an oil; the *p*-methoxyphenyl deriv. of II gives the *chromaan*, m. 85–88°. Demethylation of III with EtMgI gives *7-hydroxychroman*, m. 90°. C. J. West

3-Substituted resorcinol. IV. 5,6-Dihydroxyflavone. Kenji Nakazawa. *J. Pharm. Soc. Japan* **59**, 521–4(in German, 196 8)(1939); cf. *C. A.* **34**, 1064.—6-Hydroxy-5-methoxyflavone (0.5 g.) in 5 cc. $PhNO_2$ and 0.2 g. $AlCl_3$ when heated on the oil bath at 100° for 1 hr. gave 0.35 g. 5,6-dihydroxyflavone, $C_{15}H_{10}O_4$, m. 190°; diacetate, m. 167°; monobenzoate, m. 175°; dibenzoate, m. 195°. 5,6-Dimethoxyflavone (0.28 g.) when treated as above gave 0.15 g. 5-hydroxy-6-methoxyflavone, m. 129.5°. **V. Synthesis of primetin (5,8-dihydroxyflavone).** *Ibid.* 524–30(in German, 199–202).—2,6-$HO(MeO)C_6H_2Ac$ (8.3 g.) by the Gattermann reaction gave 3.5 g. 2-hydroxy-4-methoxy-3-acetylbenzaldehyde, m. 89.5°, which gave 2,3-dihydroxy-6-methoxyacetophenone (I), m. 147°; dibenzoate, m. 132°. I (2.4 g.), 12 g. BzOH and 3 g. BzONa when heated at 180–90° for 5 hrs. gave 1.6 g. 8-benzoyloxy-5-methoxyflavone (II), m. 216°. II (1.4 g.) when treated with H_2SO_4 gave 0.7 g. 8-hydroxy-5-methoxyflavone (primetin 5-Me ether) (III), m. 236°. Methylation of 0.38 g. III in acetone with MeI gave 0.22 g. 5,8-dimethoxyflavone (primetin di-Me ether) (IV), $C_{17}H_{14}O_4$, m. 146°. III gave by the $AlCl_3$ reaction 5,8-dihydroxyflavone (primetin), $C_{15}H_{10}O_4$, m. 230–1°; diacetate, m. 190–1°; dibenzoate, m. 219°. IV gave 5-hydroxy-8-methoxyflavone (primetin 8-Me ether), $C_{16}H_{12}O_4$, m. 210–11°. Demethylation of III with HI gave dihydroxyflavone, m. 189°, which did not depress the m. p. of 5,6-dihydroxyflavone. F. I. Nakamura

New research on the flavone derivatives from hydroxyphloroglucinol. G. Bargellini. *Atti X° congr. intern. chim.* **3**, 32(1939).—By treating AcCl with 1,2,3,5-$C_6H_2(OMe)_4$ in the presence of $AlCl_3$ there is obtained among the products *2-hydroxy-3,4,6-trimethoxyacetophenone* (I), m. 112–13°. By condensing I with anisaldehyde there is obtained *2-hydroxy-3,4,6,4'-tetramethoxychalcone* (II) which on heating with dil. HCl in alc. gives *5,7,8,4'-tetramethoxyflavanone* (III). By heating II with SeO_2 in AmOH there is obtained the corresponding *5,7,8,4'-tetramethoxyflavone*, m. 207–8°, identical with *isoscutellarein tetra-Me ether*. By treating II wth H_2O_2 in NaOH according to Algar and Flynn (cf. *C. A.* **29**, 161[8]) there is obtained *5,7,8,4'-tetramethoxyflavonol* which by demethylation with boiling HI gives *5,7,8,4'-tetrahydroxyflavonol* or herbacetin, recently synthesized by Goldsworthy and Robinson (cf. *C. A.* **32**, 2120[9]). J. C. Lo Cicero

Derivatives of pyridine and quinoline. XLIII. The formation of 2,3,4,6-tetrabromopyridine during the bromination of 2,6-dibromopyridine at about 500°. J. P. Wibaut and A. F. Bickel. *Rec. trav. chim.* **58**, 994–7(1939); cf. *C. A.* **33**, 8615[3].—The bromination of 2,6-dibromopyridine in the gaseous phase and in the presence of pumice as a contact substance has been reinvestigated in the temp. range of 500–80° (most suitable 510–20°); besides the 2,4,6-tri-Br deriv., which is the main product of the reaction (den Hertog and W., *C. A.* **27**, 508), *2,3,4,6-tetrabromopyridine*, m. 105.3–6°, and a very small amt. of the penta-Br deriv. (m. 209.5–10°) are formed. The previous yield of the tri-Br deriv. could not be duplicated. C. J. West

Synthesis of pyridinium ethanols. III. Further observations in the synthesis. Physiological action of the pyridinium ethanols. Fritz Krohnke and Alfred Schulze. *Ber.* **72B**, 2000–9(1939); cf. *C. A.* **29**, 6892[2].—As shown in the earlier papers, the methylene group in pyridinium salts of the general type $RCH_2N(C_5H_5)Br$ undergoes an aldol-like condensation with aldehydes, R'CHO, to form pyridinium ethanols, $R'CH(OH)CHRN(C_5H_5)Br$. The salts with R = acyl react with aromatic, heterocyclic and aliphatic aldehydes and the acyl group is then split off secondarily, while the salts with R = alkyl react only with aromatic aldehydes and, in part (R = benzyl, allyl), with furfural. As it has thus far not been possible to effect the condensation in an acid medium, the mechanism of the reaction with the acyl derivs. is represented by the scheme

$$RCOCH_2\overset{+}{N}(C_5H_5)Br \rightarrow R.C(\bar{O}).CH.\overset{+}{N}C_5H_5 \ (+R'CHO)$$

$$\rightarrow R.C(\bar{O})C[CH(\bar{O}H)R'].\overset{+}{N}C_5H_5 \ (I) \ (+HBr) \rightarrow R'-CH(OH)CH_2N(C_5H_5)Br + RCO_2H.$$

Attempts to isolate the intermediate I have not as yet been successful. On the other hand, *mol. compds.* (1:2) of *phenacylpyridinium chloride* and *bromide* with *m-nitrobenzaldehyde*, does not m. clear 130° and m. 135°, resp., have been obtained in alc. From the fact that they are formed in alc. and decomp. in water, it may be that in the ethanol condensation solvent forces also have a decisive influence. Unfortunately it has been possible to make but little use, for the synthesis of pyridinium ethanols, of the numerous investigations which have been carried out on aldehyde condensations, for they cannot be applied (or only in part) to the above condensation. Nevertheless, some progress has been made, in many cases by the addn. of NaBr. The role of the alkali in the reaction is that of a catalyst. The use of org. bases as the catalyst has been only partially successful; by this means it has been possible to effect, to some extent, further transformations of aromatic HO aldehydes. $NHEt_2$ has proved to be the most effective, piperidine less so, pyridine not at all. MeANOH is about as effective as alkalies. Of benzaldehydes the most reactive is the *m*-nitro compd., followed by others with electroneg. substituents, then by BzH itself; the Me, MeO and *p*-PhO derivs. react more slowly and with poorer yields, the HO derivs. even less satisfactorily, the amino and Me_2N compds. not at all. *m*-Substituted benzaldehydes, on the whole, are more reactive than the *o*- and *p*-isomers. In general, the aldehydes react with the greater

difficulty the less autoxidizable they are. Furfural behaves like an aromatic aldehyde. In the condensation to pyridinium ethanols there is noted a more or less strong red-brown color, indicating the occurrence of side reactions. If pyridine is used instead of alc. as solvent, the dye formation appears to be the chief reaction. Perhaps this is not the only side reaction; with enol betaines from RCO-CH_2NMe_2PhBr (II) there has been found another type of reaction with aldehydes whereby oxido compds. are formed: II + R'CHO → RCOCH[CH(OH)R']NMe_2-$PhBr$ → RCOCH.CHR'.O + NMe_2Ph + HBr. In the salts $RCH_2N(C_5H_5)Br$ where R = acyl the reactivity of 1 methylene H atom is decreased when the other is substituted and only 1 mol. aldehyde reacts with the salt. Only 1 exception has thus far been found. $PhCH_2CHO$ reacts normally with $PhCOCH_2N(C_5H_5)Br$ to give $PhCH_2CH$-$(OH)CH_2N(C_5H_5)Br$ (III) but there are also formed 2 other compds. (IV, V) whose compn. shows that they have been formed from 2 mols. aldehyde and 1 mol. salt. They may be either diastereomers of the structure $[PhCH_2CH$-$(OH)]_2CHN(C_5H_5)Br$, or the other methylene H atom may have been replaced by the 2nd mol. of aldehyde; in this case 4 pairs of diastereomers would be expected. The in general more difficult formation of ethanols with the grouping $-CH(OH).CHR.N\equiv$ corresponds to their lesser stability. Because of their sensitiveness to heat it had previously been possible to purify them only by repptn. from alc.-ether; it has since been found that they can be satisfactorily recrystd. from glacial AcOH. The pyridinium ethanols prepd. in the course of these investigations have been tested for their physiol. activity on the uterus, blood pressure and intestine. Many show on the rabbit, guinea pig and sheep uterus an action qualitatively similar to that of the ergot alkaloids. CCl_3CH-$(OH)CH_2N(C_5H_5)Br$ (10 mg. intravenously) lowers the blood pressure of the rabbit under urethan 40 mm. (*β*-Hydroxy-*β*-(*o*-chlorophenyl)-*α*-phenylethyl)isoquinolinium bromide is 20 times more powerful than papaverine in its action on the intestine. The following *derivs.* of (*β-hydroxyethyl*)*pyridinium bromide* (substituents on the Et group) are described: *α-phenyl-β-(α-furyl)* (75% from 3 g. $PhCH_2N(C_5H_5)Br$, 2 cc. furfural and 0.3 cc. of 10 *N* NaOH in 25 cc. alc. after 4 hrs. at 0°), m. 201–3° (decompn.), loses 4–6% in wt. at 90–110° in 30 hrs. (*picrate*, m. 108 9°, loses 6.3% at 70°); *β-(α-furyl)* (55% from 5 g. $PhCOCH_2N(C_5H_5)Br$ in 55 cc. 90% alc., 2.25 g. furfural and 3 cc. 10 *N* NaOH allowed to stand 3 days), m. 183–215°, depending on the rate of heating (perchlorate, m. 151 2°); *β-(m-nitrophenyl)*, obtained in 33% yield from the components refluxed 2.5 hrs. with $NHEt_2$; *β-(m-hydroxyphenyl)* (47% from 3 g. $PhCOCH_2N(C_5H_5)Br$, 2.4 g. HOC_6H_4CHO and 3 g. NaBr in 50 cc. of 90% alc. treated at 0° with 1.2 cc. of 10 *N* NaOH and an addnl. 1.2 and 0.75 cc. after 1 hr. and after another 15 min., resp.; without NaBr the yield is 10%), m. 268° (decompn.); *α-vinyl-β-phenyl* (45.5 g. from 25 g. allyl bromide in 50 cc. alc., 17 cc. pyridine, 25 cc. BzH and 2 cc. of 10 *N* NaOH at 0°), m. 215° (perchlorate, m. 153°; *Ac deriv.*, prepd. with boiling Ac_2O-AcOH, m. 157–8°, loses 2% at 80°); *α-vinyl-β-(m-hydroxyphenyl)* (almost quant. with $NHEt_2$), rhombohedrons from 80% AcOH, m. about 195°, octa- and polyhedrons from 8.8 *N* HBr, m. 236° (decompn.) (*perchlorate*, m. 170°); *o-HO isomer* (28%), m. 159 60°; *α-vinyl-β-(m-nitrophenyl)* (96%), m. 163 5°; *p-nitro isomer* (62% from 1 g. allylpyridinium bromide, 1 g. $O_2NC_6H_4CHO$ and 0.07 cc. of 10 *N* NaOH in 15 cc. alc. allowed to stand 6 hrs. at 0°), m. 203° (decompn.); *α-vinyl-β-(m-chlorophenyl)* (98% with $NHEt_2$), m. 200–1°; *α-phenyl-β-(o-chlorophenyl)* (55%), m. 242°; *α-methyl-β-(m-nitrophenyl)* (17%), m. 212–14°, *β-(p-phenoxyphenyl)* (43% from 5 g. $PhCOCH_2N(C_5H_5)$-Br, 5 cc. $PhOC_6H_4CHO$ and 1.8 cc. of 10 *N* NaOH in 55 cc. alc. after 3 days at 0°), m. 98 100°, loses about 3%; *β-(m-bromophenyl)* (76%), m. 232–3°; *α,β*-diphenyl (*acetate*, leaflets with 3 H_2O, m. (dried), 225°). [*α-(m-Nitrophenyl)-β-(o-nitrophenyl)ethyl*]*pyridinium chloride* (90% with $NHEt_2$), m. 212°. *Picrate* of **III**, golden yellow, m. 162°; of **IV**, needles with 1 H_2O, m. 108–13° (*perchlorate*, leaflets with 2 H_2O, m. 81–2°); of **V**, needles with 1 H_2O, m. 173.5°. (*β-Hydroxy-β-benzylethyl*)*pyridinium chloride*, from $PhCH_2CH(OH)CH_2Cl$ refluxed 2.5 hrs. with 2 vols. pyridine and pptd. with ether, m. 142–3°; the picrate is identical with that of III. *N-(γ,γ,γ-Trichloro-β-hydroxypropyl)-3-bromopyridinium bromide* (40% from $PhCOCH_2N(C_5H_4Br)Br$ and CCl_3-$CHO.H_2O$), m. 215° (decompn.); *N-(β-hydroxy-β-nitrophenylethyl) analog* (40%), m. 261° (decompn.); *N-(β-hydroxy-β-phenylethyl) compd.* (28%), m. 206–8°. *α,β*-Oxido-*α*-phenyl-*β*-(*m*-nitrobenzoyl)ethane (40 mg. from 600 mg. *m*-nitrophenacyldimethylphenylammonium enol betaine and 0.2 cc. BzH in alc.), m. 199°; *α-(m-nitrophenyl)-β-(m-nitrobenzoyl)* analog (56%), m. 185°; *α-(m-nitrophenyl)-β-(p-bromobenzoyl)* compd. (72%), m. 134°. C. A. R.

Electron-sharing ability of organic radicals. X. α-Substituted tetrahydroquinolines. Wilbur Oldham and I. B. Johns. *J. Am. Chem. Soc.* **61**, 3289–91(1939); cf. *C. A.* **29**, 7717⁴. *α*-Substituted quinolines were prepd. from quinoline and RMgX or RM_2; the Bu deriv. was prepd. by the reaction of $NaNH_2$ on quinaldine, followed by PrBr; reduction to the tetrahydro derivs. was accomplished by Na in boiling EtOH. *α*-Methyltetrahydroquinoline (I), b_{17} 125°, results in 70% yields; *α*-Et deriv. (II), b_5 110–13° (62%) (picrate, m. 119–20°); *Bu deriv.* (III), b_6 138° (55%) (*p-bromobenzenesulfonamide*, m. 160–60.5°); Ph deriv. (IV), b_8 196° (73%) (picrate, m. 129°; *p-bromobenzenesulfonamide*, m. 201 2°); *α-p-tolyl deriv.* (V), b_{14} 210° (73%) (*picrate*, m. 134–4.5°). *α-o-Tolylquinoline*, b_4 197°, m. 76 6.2°, results in 90% yield by the use of *o*-MeC_6H_4Li, followed by dehydrogenation with $PhNO_2$; *picrate*, m. 176°; *tetrahydro deriv* (VI), b_8 200 2°, m. 69.5° (*p-bromobenzenesulfonamide*, m. 193–3.5°). *α 2-Mesitylquinoline*, b_1 200°, m. 69 9.5°, *picrate*, m. 216.5°; *tetrahydro deriv.* (VII), b_6 218° (*picrate*, m. 164.5 5°). Ionization consts. were measured by the method of Goodhue and Hixson (*C. A.* **28**, 4378⁵); values for $pK_{BH,OH}$ are: VII 12.92, VI 12 18, IV 12.18, V 11.94, I 10.90, II 10.87, III 11.08, unsubstituted 10.90. These consts., plotted against electron-sharing ability functions, give a curve similar to that for a series of *α*-substituted pyrrolidines (G. and H.). C. J. West

Synthesis of alkyl-substituted substances of the quinoline series. E. S. Vasserman. *Trudy Dnepropetrov Khim.-Tekhnol. Inst. im. F. E. Dzerzhinskogo, Kafedra Org. Khim.* **1938**, 68–72; *Khim. Referat. Zhur.* **2**, No. 4, 56 (1939). The object of the expts. was the application of Komb's method for the prepn. of 2,4-dimethylquinolines to different aromatic amines and to their derivs. When used with aniline the scheme of the reaction is as follows: $PhNH_2$ + $MeCOCH_2COMe$ → PhN $CMeCH_2COMe$ + H_2SO_4 → $C_6H_4.N$ $CMe.CH$ CMe. From *p*-toluidine and CH_2Ac_2 was obtained 2,1,6-trimethylquinoline, m. 43–5°. From *α*- and *β*-naphthylamines and CH_2Ac_2 were obtained 2,4-dimethyl-*α*-, m. 44°, and *β*-naphthoquinoline, m. 66–7°. Aniline with $BzCH_2Ac$ gives similarly 2-methyl-4-phenylquinoline, m. 100°. *p*-Toluidine with $BzCH_2Ac$ gives 2,6-dimethyl-4-phenylquinoline, m. 78°. The Komb reaction does not take place when aromatic amines with halogen and with nitro groups in the *o*- and the *p*-positions are used. W. R. Henn

Methods for the preparation of the starting substances for sensitizers of the quinoline series—isocyanines. V. A. Alekseeva. *Trudy Dnepropetrov. Khim. Tekhnol. Inst. im. F. E. Dzerzhinskogo, Kafedra Org. Khim.* **1938**, 73–83; *Khim. Referat. Zhur.* **2**, No. 4, 56(1939); cf. *C. A.* **32**, 2449.— The object of the expts. was the prepn. of different derivs. of quinoline which can be used as starting materials for the synthesis of isocyanines. According to Konrad-Limpach [*Ber.* **20**, 944, 980, 1397(1887)] the reaction proceeds according to the following scheme: *p*-$MeC_6H_4NH_2$ + $MeCOCH_2CO_2Et$(−H_2O) → MeC_6H_4N:$CMeCH_2CO_2$-Et(−EtOH) → $MeC_6H_3.N.CMe.CH_2.CO$ → $MeC_6H_3.N$:

$CMe.CH:COH$. The condensation reaction with $AcCH_2$- CO_2Et and the further ring formation were performed completely with *p*-toluidine and α- and β-naphthylamine. Besides this, condensation products (anils) were obtained with $AcCH_2CO_2Et$ and xylidine (1:3:4), *o*- and *p*-$C_6H_4(NH_2)_2$ and benzidine. The ring formation with the anils was obtained by a rapid heating to 240° in a kerosene medium with the use of a mixer. The yield of the corresponding hydroxyquinaldine was greatly increased (to 87.6%). W. R. Henn 1

Preparation of some *py*-aminoquinolines and their derivatives. R. R. Renshaw and H. L. Friedman. *J. Am. Chem. Soc.* **61**, 3320–2(1939).—Reduction of 3-nitroquinoline gives 3-aminoquinoline (I) in small over-all yields; 3-bromoquinoline, heated with concd. NH_4OH and $CuSO_4$ 12 hrs. at 160°, gives 73% I. The Ac deriv. of I and HNO_3 in AcOH give the *nitrate*, m. 195.5° (decompn.); fuming HNO_3 in concd. H_2SO_4 gives the *Ac deriv.*, golden yellow, m. 205–6°, of *3-amino-4(?)-nitroquinoline* (II), red, m. 189–9.5°, which could not be reduced in HCl with $SnCl_2$ or other reagents. The diazo soln. from 200 mg. II, poured into EtOH and boiled, gives 40 mg. of *3-ethoxy-4(?)-nitroquinoline*, tan, m. 113–14°. Decarboxylation of quinoline-2,4-dicarboxylic acid (III) in boiling $PhNO_2$ for 10 min. gives 90% of cinchoninic acid; through the acid chloride, Me ester and amide 4-aminoquinoline results in an over-all yield of 68%. III through the acid chloride (IV) yields the *di-Me ester* (V), m. 130–1°, and the *di-Et ester* (VI), m. 74–5.5°; IV and $PhNH_2$ give *quinoline-2,4-dicarboxanilide*, bluish white, m. 285–6°. Heating V with MeOH-NH_3 at 80° for 20 hrs. gives 2,4-dicarbamylquinoline, m. 277.5–9.5°; KOH and Br give 85% (over-all yield 59%) of *2,4-diaminoquinoline*, m. 197–8.5° (*picrate*, m. 283° (*decompn.*)). Heating VI with MeOH-NH_3 at 50° gives 86% of *2-carbomethylethyl cinchoninate*, m. 226–7.5°; KOH and Br give 2-aminocinchoninic acid, tan, m. 362° (decompn.) All m. ps. are cor. C. J. West 2

4-Phenyl-4-aminoquinoline derivatives. U. P. Basu and P. K. Das-Gupta. *J. Indian Chem. Soc.* **16**, 301–4 (1939). 2 - Phenyl - 4 - (4' - aminobenzenesulfonyl)-aminoquinolines may have some therapeutic importance since the monosubstitution of the H_2NSO_2 group of $H_2NSO_2C_6H_4NH_2$ (I) often widens the scope of activity of the drug. A mixt. of 4.4 g. of 2-phenyl-4-aminoquinoline (II) (*C. A.* **20**, 3010[8]), 4 g. $Et_2NCH_2CH_2Br$, 2 g. anhyd. K_2CO_3 and a trace of Cu powder in xylene was refluxed for 12 hrs. The ext. with dil. HCl was neutralized with K_2CO_3 and extd. with Et_2O. Treatment with excess K_2CO_3 and extn. of the oil with Et_2O gave viscous yellow liquid *2-phenyl-4-(β-diethylaminoethyl)aminoquinoline*, $C_{21}H_{25}N_3$, b_6 272–6°, n_D^{33} 1.6510; *picrate*, m. 238–9°. Similarly were produced the corresponding compds.: *γ-diethylaminopropyl*, b_6 265–70° (*picrate*, m. 234°) and its *6-MeO deriv.*, m. 159°; *δ-diethylaminobutyl* (*picrate*, m. 203°) and its *6-MeO deriv.* (*picrate*, m. 192°); and *δ-diethylamino-α-methylbutyl* (*picrate*, m. 162°). Condensation of 2-phenyl-4-chloroquinoline with I in the presence of Cu powder gave *2-phenyl-4-(4'-sulfonamidophenyl)-aminoquinoline*, $C_{21}H_{17}N_3O_2S$, m. 250°. The corresponding *diethylsulfonamido compd.*, $C_{25}H_{25}N_3O_2S$, m. 144°, was similarly prepd. Condensation of II with *p*-$AcNHC_6H_4SO_2Cl$ in benzene and hydrolysis of the product with HCl (d. 1.16) gave *2-phenyl-4-(4'-aminobenzenesulfonyl)aminoquinoline*, $C_{21}H_{17}N_3O_2S$, m. 293°; *Ac deriv.*, m. 297°. Similarly was produced the corresponding *6-MeO compd.*, $C_{22}H_{19}N_3O_3S$, m. 268°; *Ac deriv.*, $C_{24}H_{21}N_3O_4S$, m. 268°. The yield of these condensation products was invariably poor. No therapeutic activity data are reported. C. R. Addinall 3

Quinovic acid from Zygophyllum coccineum L. Gabra Soliman. *J. Chem. Soc.* **1939**, 1760–1.—The annual shrub *Zygophyllum coccineum* L. (gasshul, rotreyt or kemmun quaramany of Egypt), on extn. of 3 kg. with petr. ether and then with Et_2O or EtOH, gives after a lengthy purification 19 g. of quinovic acid, m. 297° (decompn.), identical with that which occurs in cinchona bark. *O-Ac deriv.*, m. 282–4° (decompn.); Me ester, m. 175° (*O*-Ac deriv., m. 218°). C. J. West 4

Pyrimidines. The molecular rearrangement of 4-methyl - 5 - propyl - 2,6 - dimethoxypyrimidine. Youh-Fong Chi, Shao-Seng Wei and Mei-Seng Liang. *J. Am. Chem. Soc.* **61**, 3377–9(1939).—4-Methyl-5-propyluracil (I) and $POCl_3$, refluxed 12 hrs., give 80% of *4-methyl-5-propyl-2,6-dichloropyrimidine*, $b_{19.5}$ 145–6°, b_{35} 163°, m. 31–3°; MeONa gives the *2,6-di-MeO deriv.* (II), $b_{19.5}$ 135–40°, and EtONa gives the *2,6-di-EtO deriv.*, b_{18} 145–8°. Heating II at 260–80° for 3 hrs. gives 90% of *1,3,4-trimethyl-5-propyluracil* (III), m. 74–5°. II and excess MeI, heated at 50–60° for 8 hrs., give *2-hydroxy-3,4-dimethyl-5-propyl-6-methoxypyrimidine* (IV), $b_{4.5}$ 180–2°; hydrolysis of IV with dil. HCl gives *3,4-dimethyl-5-propyluracil*, m. 148–50°. Methylation of I with Me_2SO_4 and NaOH or MeONa gives *1,4-dimethyl-5-propyluracil*, m. 193.5–4°. Heating IV at 330–50° for 6–8 hrs. gives III. C. J. West 5

α,ω-Amino alcohols. I. *N*-Phenyl-*N'*-(ω-hydroxyalkyl)piperazines from α,ω-chlorohydrins. Derivatives of piperazine. 17. Geo. W. Anderson and C. B. Pollard. *J. Am. Chem. Soc.* **61**, 3439–40(1939).—The general procedure consisted in heating 0.2 g. of the chlorohydrin with 0.4 mole of *N*-phenylpiperazine for 5 hrs. on the water bath, heating the solid with 40 cc. 5 *M* K_2CO_3 and recrystg. the solidified orange-colored layer from 60% EtOH. In all but the 1st compd. the yield of crude product was practically quant. Cor. m. ps. are given for the *N-phenyl-N'-(ω-hydroxyalkyl) piperazines*, $PhNC_4H_8N(CH_2)_nOH$ (*alkyl* given) and their *phenylurethans: butyl*, 59–60°, 91.2°; *amyl*, 74–5°, 100–1.5°; *hexyl*, 65.5–7°, 91.5–3°; *heptyl*, 75.5–6.5°, 96.5–7.5°; *octyl*, 57–8.5° (*hydrate*, m. 80–2°), 99.5–100.5°; *nonyl*, 80–80.5°, 94–5°; *decyl*, 67–8°, 95–6°. *α-Naphthylurethan* of *hexamethylene-α,ω-chlorohydrin*, m. 49–50°; *decamethylene analog*, m. 63–4°. **II. Morpholino alcohols. Derivatives of morpholine.** 2 *Ibid.* 3440–1.—Heating approx. 0.5 mole of morpholine and α,ω-glycol in 300 cc. dioxane with Cu-Cr oxide catalyst at 235–70° for 6 hrs. at 100 atm. gives a mixt. of morpholinoalkanol, $O(CH_2CH_2)_2N(CH_2)_nOH$ (I), and dimorpholinoalkane, $[O(CH_2CH_2)_2N]_2(CH_2)_n$ (II); yields of I and II are (*alkane* given): *butane*, 36, 22; *pentene*, 31, 28; *hexane*, 21, 18; *heptane*, 19, 28; *octane* 26, 41; *nonane*, 38, 28; *decane*, 21, 13. Properties of I (*alkane* given): *butane*, b_6 116.5–7°, n_D^{25} 1.4745, d_4^{25} 1.018 (*phenylurethan*, m. 86–7° (m. ps. of derivs. cor.)); *pentane*, b_6 133–3.5°, n_D^{25} 1.4755, d_4^{25} 1.005 (*phenylurethan*, m. 55.5–7°); *hexane*, b_6 146–7°, n_D^{25} 1.4750, d_4^{25} 0.9884 (*α-naphthylurethan*, m. 71–2°); *heptane*, b_6 155.5–8°, n_D^{25} 1.4747, d_4^{25} 0.9783 (*phenylurethan*, m. 71–2°); *octane*, b_6 164–4.2°, n_D^{25} 1.4735, d_4^{25} 0.9675 (*α-naphthylurethan*, m. 73–4°); *nonane*, b_6 173–3.5°, m. 31° (*α-naphthylurethan*, m. 54–6°); *decane*, b_2 164–5°, m. 39.5–40° (*α-naphthylurethan*, m. 66.5–7.5°). Properties of II: *butane*, b_6 147.5–8.5°, m. 51.5–2.5°; *pentane*, b_6 161–2°, n_D^{25} 1.4804, d_4^{25} 0.9980; *hexane*, b_6 169.5–71°, m. 35.5–8.5°; *heptane*, b_6 183–4°, n_D^{25} 1.4796, d_4^{25} 0.9789; *octane*, b_6 191.5–3.5°, m. 46.5–7.5°, 48° (double m. ps., not complete resolidification after 1st melting but distinct crystal formation); *nonane*, b_6 203.5–4°, n_D^{25} 1.4789, d_4^{25} 0.9639; *decane*, b_2 187–9°, m. 49–9°, 50.5–1.5°. C. J. West 6 7 8

Constitution and synthesis of the alkaloid anonaine. G. Barger and G. Weitnauer. *Helv. Chim. Acta* **22**, 1036–47(1939).—Percolation of the bark of *Anona reticulata* with 95% alc. gave 0.12% of anonaine (I), $C_{17}H_{15}NO_2$, m. 122–3°, $[\alpha]_D^{19}$ −52°; *HCl salt*, m. 277.5° (decompn.); *nitroso deriv.*, m. 229–30°; *Ac deriv.*, m. 229–30°; *N-Me deriv.* (II) (*HI salt*, m. 246–7° (decompn.)). I is a secondary, non-phenolic base, contg. 1 active H atom and a CH_2O_2 group but giving neg. tests for NMe, MeO, CO_2H, CO and indole groupings. Oxidation with $KMnO_4$ yielded a small amt. of o-$C_6H_4(CO_2H)_2$ and the structure of I was assumed to be of the aporphine type. Proof of this assumption was advanced by the results of Hofmann degradation expts. The *quaternary ammonium iodide*, $C_{19}H_{20}INO_2$, m. 217°, was boiled for several hrs. with alc. KOH and yielded 91% of a *methine*, m. 87–90°; MeI deriv., m. 9

270.5° (decompn.), converted by refluxing with 5% KOH in MeOH to a substituted *vinylphenanthrene*, $C_{17}H_{12}O_2$, m. 87°. Oxidation with $KMnO_4$ in acetone produced an acid, $C_{16}H_{10}O_4$, m. 240° (decompn.), which was decarboxylated according to Reichstein (*C. A.* **27**, 1333) with Cu chromite and quinoline to a *methylenedioxyphenanthrene*, $C_{15}H_{10}O_2$; picrate, m. 168° (decompn.). All known aporphine alkaloids with 1 exception have the CH_2O_2 group in the 5,6-position and accordingly this was assumed to apply to I. Proof of the assumption was sought in a synthesis of I according to a scheme commonly used for aporphine alkaloids. A mixt. of 18.1 g. of o-$O_2NC_6H_4CH_2CO_2H$ and 60 cc. $SOCl_2$ in 100 cc. $CHCl_3$ was kept at 40° for 30 min. After distn. at reduced pressure the resulting acid chloride was taken up in 30 cc. of benzene and the soln. was added dropwise to a cool soln. of 31 g. of homopiperonylamine in 40 cc. benzene. The crude product was extd. with boiling dil. AcOH and recrystd. from MeOH, yielding 85% of *3-3,4-methylenedioxyphenyl)ethyl-o-nitrophenylacetamide* (III), $C_{17}H_{16}N_2O_5$, m. 119°. Treatment of 5 g. III in 20 cc. $CHCl_3$ with 15 cc. $POCl_3$ for 5 days at room temp. gave 79% of *2'-nitro-6,7-methylenedioxy-1-benzyl-3,4-dihydroisoquinoline* (IV), $C_{17}H_{14}N_2O_4$, m. 165°, reduced by Zn dust in HCl to crude oily *2'-amino-6,7-methylenedioxy-1-benzyltetrahydroisoquinoline* (V); *di-HCl salt*, m. 257°. V (6.68 g.) in 180 cc. of 2 *N* H_2SO_4 was diazotized with 0.5 *N* $NaNO_2$ and heated on the steam bath for 30 min. The mixt. was treated with 3 g. Zn dust and 8 cc. concd. HCl, heated for 30 min., filtered, cooled, shaken out with Et_2O and made strongly alk. The pptd. base was taken up in Et_2O and recrystd. from HCl in Et_2O, yielding 22% of white needles of the *HCl salt* of I, m. 255° (decompn.); *Ac deriv.* of I, m. 217°. The Hofmann degradation of synthetic I gave an identical series of products as the natural base. Synthetic I gave the same color reactions as the natural product. A mixt. of 3.6 g. IV and 10 cc. MeI was heated for 30 min. in a sealed tube at 100°, producing 93% of yellow platelets of the *MeI deriv.*, $C_{18}H_{17}IN_2O_4$, m. 243° (decompn.), reduced by Zn in HCl to *2'-amino 6,7-methylenedioxy-1-benzyl-2-methyltetrahydroisoquinoline* (VI); *di-HCl salt*, m. 259-60° (decompn.). Diazotization of VI in H_2SO_4, heating on the steam bath for 30 min., reduction, filtration, extn. with Et_2O and addn. of excess alkali gave a base. Extn. with 2 *N* HCl and treatment with KI yielded prisms of *dl-N-methylanonaine-III*, $C_{18}H_{17}NO_2$.HI, m. 244° (decompn.); *MeI deriv.*, m. 210-11°, identical with the corresponding product prepd. from synthetic I. N-Methylanonaine is probably identical with the alkaloid roemerine recently isolated from *Roemeria refracta* (*C. A.* **33**, 6325[1]). C. R. Addinall

Alkaloids of Menispermaceae. L. Alkaloids of Stephania sasakii, Hayata. 1. Hisaburo Kondo and Masao Tomita. *J. Pharm. Soc. Japan* **59**, 542-6(in German, 207-8)(1939).—From the alc. ext. of *Stephania sasakii*, Hayata, T. obtained a base as the Bz deriv. (I), m. 103°, which corresponds to cepharanthine, m. 103°, isolated from *Stephania cepharantha*, Hayata. I gave 3 free bases: (1) $C_{37}H_{38}N_2O_6$; $[\alpha]_D^{15}$ 296.6° (in $CHCl_3$); α-methine base m. 98-100°, and β-methine base m. 183°. (2) $C_{38}H_{40}N_2O_7$, m. 115-17°, $[\alpha]_D^{20}$ −57.1° (in $CHCl_3$); HCl salt, m. 222.5°; methiodide, $C_{38}H_{40}N_2O_7.2MeI.H_2O$, m. 220°; methine base, $C_{40}H_{44}N_2O_7.H_2O$, m. 110-14°. (3) $C_{36}H_{36}N_2O_7$, m. 210°, $[\alpha]_D^{20}$ −36.7 (in $CHCl_3$), is phenolic in character; HCl salt, m. 264°. The free base contains 2 OMe groups, but on methylation with CH_2N_2 forms a compd., m. 160-5°, with 4 OMe groups. F. I. Nakamura

The *N*-alkyl- and the *N*-arylmorpholones (2-ketotetrahydro-1,4-oxazines). A. I. Kiprianov, A. P. Tisel'skii and I. K. Ushenko. *Trudy Khar'kov. Gosudarst. Univ.* **3**, 45-52(1938); *Khim. Referat. Zhur.* **2**, No. 4, 54-5(1939). —By boiling the alkyl- and the arylaminoethanols with $ClCH_2CO_2Na$ were obtained Me, Et, Pr, iso-Pr, iso-Am, $PhCH_2$, Ph and *o*- and *p*-MeC_6H_4 derivs. of morpholone. In case of the aryl derivs. morpholones are formed directly:

$$ArNHCH_2CH_2OH + ClCH_2CO_2Na \rightarrow CH_2.CH_2.NAr\text{-}CH_2.CO.O + NaCl + H_2O \text{ (I)}.$$

In case of the alkylaminoethanols the hydroxyalkylamino acids are formed first and are dehydrated to the corresponding alkylmorpholones by distn. *in vacuo*. The alkylmorpholones are easily hydrolyzed. By the action of concd. NH_3 on the arylmorpholones the amino acids, *N*-aryl-*N*-β-hydroxyethylaminoacetic acids, were obtained. The product of the condensation of *N*-phenylmorpholone with Michler's ketone was obtained in the form of an amorphous iodide.

Its probable structure is $Me_2NC_6H_4CR\ C_6H_4{:}\overset{+}{N}Me_2 + I$ (R = *p*-$CH_2.CH_2.O.CO.CH_2.NC_6H_4$-) (II). For the prepn. of *N*-methylmorpholine 17 g. of $ClCH_2CO_2H$ in 35 cc. of water are neutralized with concd. NaOH, boiled for 7 hrs. with 13.5 g. of $MeNHCH_2CH_2OH$, evapd. on a water bath and the residue distd. *in vacuo*. The yield was 8.4 g., colorless liquid, b_{10} 100-2°, b. 233°. [Knorr, *Ann.* **307**, 199 (1899).] A yield of 14 g. of *N*-ethylmorpholone (14 g. from 15.6 g. of $EtNHCH_2CH_2OH$ [Knorr and Schmidt, *Ber.* **31**, 1073(1898)], colorless mobile liquid, b_7 97-9.5°. By hydrolysis was obtained *N*-ethyl-*N*-β-hydroxyethylaminoacetic acid, colorless crystals. A yield of 8 g. of *N*-propylmorpholone was obtained from 17 g. of propylethanolamine, b_{20} 130-6°, as a dense colorless liquid. *N*-Propyl-*N*-β-hydroxyethylaminoacetic acid is a non-crystg. syrup. The Cu salt $(C_{11}H_{23}O_6NCu.3H_2O)$ forms dark blue needles. A yield of 2.5 g. of *N*-isopropylmorpholone was obtained from 7 g. of isopropylaminoethanol, b_8 78-80°. A yield of 5 g. of *N*-isoamylmorpholone was obtained from 11 g. of isoamylaminoethanol, b_{20} 150-5°. A yield of 11 g. of *N*-benzylmorpholone was obtained from 12 g. of benzylaminoethanol (boiling for 15 hrs.) b_8 158-61°. *N*-Phenyl-*N*-β-hydroxyethylaminoacetic acid was obtained from *N*-phenylmorpholone (III) [Kiprianov, *C. A.* **24**, 1081] with concd. NH. The methyl ether of *N*-phenyl-*N*-β-hydroxyethylaminoacetic acid yields III during the distn. *in vacuo*. From the reaction of 10.5 g. of *o*-toluidine and 14.7 g. of ethylene oxide in a sealed tube at 100° for 8 hrs. was obtained *N*-β-hydroxyethyl-*o*-toluidine (IV) in the form of a yellow oil, b_8 168-74°. By boiling 32.2 g. of IV for 8 hrs. *N*-*o*-tolylmorpholone, b_7 186-7°, was obtained. *N*-β-Hydroxyethyl-*N*-*o*-tolylaminoacetic acid was obtained in the form of colorless needles, m. 113-14°. From *p*-toluidine and ethylene oxide was obtained *N*-(β-hydroxyethyl)-*p*-toluidine (V), b_{20} 183-92° and m. 39°. From V white crystals of *N*-*p*-tolylmorpholone were obtained, m. 71-8° (sealed tube). White crystals of *N*-*p*-tolyl *N*-β-hydroxyethylaminoacetic acid were obtained from alc., m. 170-2°. W. R. Henn

Lupine studies. XIV. The isolation of anagyrine from Lupinus laxiflorus var. silvivola C. P. Smith. James F. Couch. *J. Am. Chem. Soc.* **61**, 3327-8(1939); cf. *C. A.* **33**, 6320[8]. The dried plant of *Lupinus laxiflorus* var. *silvicola* C. P. Smith (western U. S.) gives 0.7-0.97% of anagyrine (I); cytisine, methylcytisine and sparteine were not found. I b_{12} 260-70°, $[\alpha]_D^{25}$ −168° (1% in OH, *c* 1.0596); the HCl salt seps. with 3 moles H_2O, m. 235-6°, and also with 0.5 mole H_2O, m. 284.5-5.5°; $[\alpha]_D^{25}$ −124.2° (H_2O, *c* 1.7316); perchlorate, long needles, decompg. without melting; *chloroaurate*, golden needles, m. 167-8°; picrate, m. 169.5°; *methiodide*, m. 262-3°. I on filter paper, exposed to Br vapor, gives an orange-yellow color, which develops a pale-blue color with NH_3 and on heating it changes to brown instead of scarlet as in the case of sparteine (modified Grant test). C. J. West

β-Elemonic acid. M. Mladenović and I. Berkeš. *Monatsh.* **72**, 417-26; *Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIb, **148**, 115-24(1939).—Previous work (*C. A.* **30**, 2979[4]) had shown that β-elemonic acid (I) is probably identical with Ruzicka's δ-elemic acid (*C. A.* **27**, 1339) and is present as such in the native resin acid mixt. Treatment of this mixt. with $NH_2OH.HCl$ and AcONa and fractionation of the oximes yield the oxime of I, from which I can be regenerated by acids. The use of the oxime also furnishes a convenient method for isolating I from the mixt. of products from the oxidation of the elemic acid. Catalytic reduction (PtO_2 in EtOH) of I gives a

dihydro deriv. (II), $C_{30}H_{48}O_3$, m. 248° and gives no characteristic color reactions. II and HBr in $CHCl_3$ give a *monohydro deriv.* (III), $C_{30}H_{47}O_3Br$, m. 245° (decompn.); KOH in MeOH (boiled 15 min.) regenerates I; catalytic reduction (Pd in EtOH) gives II. I and Br in $CHCl_3$ (cooling with ice) give the *di-Br deriv.*, m. 223° (decompn.); KOH-MeOH gives a *Br deriv.*, $C_{30}H_{45}O_3Br$, m. 273°. I and O_3 in $CHCl_3$ (2 hrs.) give a *diozonide*, m. 80° (decompn.); further action of O_3 (4 hrs. in all) gives a *triozonide*. III yields a *mono-* and a *diozonide*, and II gives a *monoozonide*, m. 243° (decompn.), and a *diozonide*. The Me ester of I m. 119°; of II, m. 115°. The oxime of I could not be reduced to an amine; the oxime could not be degraded by PCl_5. The behavior of I and its derivs. with O_3 indicates the presence of 3 double bonds, although hydrogenation indicates only 1 and values for the enol reaction indicate 2. The difficulties of applying the latter method to compds. such as I are discussed. One double bond is considered active and the other 2 as inactive. C. J. West

Pachymic acid, a new constituent of bukuryo (Poria cocus, Wolf). I. Sokiti Nakamisi, Mitiko Yamanoto and Hukuko Ikeda. *J. Pharm. Soc. Japan* **59**, 725–9, *Abstracts* (in English) 273–6(1939).—"Bukuryo" is one of the important oriental drugs. Extn. with MeOH or AmOH of the ether ext. of the drug gave a cryst. substance (I) and a gelatinous mass. Recrystn. of I from MeOH or Me_2CO gave a compd. $C_{30}H_{44}O_6$, needles, m. 300°; Liebermann reaction pos. It is a monobasic acid, having 1 lactone, and 1 OH group and 1 double bond. It is named *pachymic acid* (II), from *Pachyma hoelen*. *Acetate*, m. 225°. II and CH_2N_2 gave a Me ester, needles, m. 175°, $[\alpha]_D^{19}$ 29.69°. *Me ester of the acetate*, m. 155°, prisms $[\alpha]_D^{23}$ 8.18°. Nao Uyei

Constituents of Lentinus tuber-regium, Fr. Sokiti Nakamsi, Mitiko Yamanoto and Tie Nakamura. *J. Pharm. Soc. Japan* **59**, 730–1(in English, 276–7)(1939).—*Lentinus tuber-regium* (I) is imported into Japan from the Micronesia and East Indies as a substitute for bukuryo. But the two drugs are different in appearance and the chem. reactions of their sclerotium. From the ether ext. of I, a sterol, $C_{27}H_{46}O_4$, needles, m. 112°, and a wax, m. 80°, were isolated. Nao Uyei

A phytochemical study of Asclepias syrica L. Alfred E. Rheineck. *Pharm. Arch.* **10**, 93–6(1939); cf. *C. A.* **33**, 9361⁴.—Amyrin acetate, propionate (m. 178°), trichloroacetate (m. 168–70°, 204°), benzoate and stearate (m. 75°) are prepd. and described. The hydrocarbon also occurring in the follicle walls was found to contain H 13.08% and C 96.43%. H. M. Burlage

Calycanthine. IV. Structural formula. Richard H. F. Manske and Léo Marion. *Can. J. Research* **17, B**, 295–301(1939); cf. *C. A.* **33**, 3798⁸.—Anhyd. calycanthine (I) (2 g.) was heated with Se (2 g.) at 300° for 30 min. in a N atm. The distillates and melts from 5 batches were worked up separately and yielded skatole (II), β-ethylindole (III), lepidine (IV), norharman (V) and a base, calycanthine (VI), $C_{21}H_{13-15}N_3$, m. 210° (all m. ps. cor.). A mixt. of 2 g. I with 2 g. Pd-charcoal catalyst was heated to 200° and at 200–10° for 5 hrs. in a stream of N passing into dil. HCl. NH_3 was liberated. Benzoylation of I and subsequent oxidation with $KMnO_4$ in acetone yielded benzoyl-*N*-tryptamine, BzOH and an amorphous *acid* (VII), $C_{18}H_{18-20}N_2O_{3-4}$, m. 170–4°, giving a pos. reaction with Ehrlich's reagent on boiling. Heating VII with Se produced quinoline. Boiling benzoylated I for several hrs. with alc. KOH gave a *base*, $C_{36}H_{34}N_4O_2$, m. 235°, for which a structure is proposed. A structural formula for I, based on the above transformations, is suggested which accounts for the dehydrogenation of VII to quinoline. The source of II, III and V is attributed to the carboline half of the mol. of I and the isolation of IV makes it possible to link the Me group of IV to the indole N of the carboline half. The ready formation of NH_3 is accounted for by the assumption of a reduced pyrrole ring contg. the 4th N atom of I. The constitution of I and VI proposed by Barger, *et al.* (*C. A.* **33**, 5405⁸) is discussed. C. R. Addinall

Newest developments in the chemistry of the glucosides. M. Bergol'ts. *Farmatsiya* **1938**, No. 1–2, 10–17; *Khim. Referat. Zhur.* **2**, No. 3, 53(1939).—A short history of the study of the glucosides of digitalis. The investigated substances are enumerated. Their structures are given in connection with the structures of sterols, bile acids and hormones which are based on the cyclopentaphenanthrene ring. The compn. of some glucosides and of their aglucone parts are given. W. R. Henn

The synthesis of isoprimeverose, of α-1-*d*-xylosido-6-*d*-glucose, and of an α-isomer and derivatives of primeverose. Géza Zemplén. *Math. naturw. Anz. ung. Akad. Wiss.* **58**, 356–78(1939); cf. *C. A.* **33**, 4965⁶.—A new optically active (*d*-rotatory), cryst. α-acetochloro deriv. could be sepd. from the mother lyes obtained in the synthetic production of primeverose derivs. (cf. *C. A.* **33**, 2110⁶). The compd., α-acetochloro-α-1-*d*-xylosido-6)-*d*-glucose, has been named α-acetochloroisoprimeverose. This gave in anhyd. AcOH with AgOAc a mixt. of α- and β-heptaacetylisoprimeverose (with the β-form as dominant part) which, further, was transformed with Ag_2CO_3 in MeOH to β-1-Me hexaacetylisoprimeveroside. The hepta-Ac deriv. is easily sapond. and yields free isoprimeverose. The detailed data of the compds. are: primeverose, m. 208–10°, $[\alpha]_{20}^{D}$ 24.1° → −3.3° (in water); isoprimeverose, m. 200–1°, $[\alpha]_{20}^{D}$ 151.3 → 121.3° (water); β-heptaacetylprimeverose, m. 216°, $[\alpha]_{20}^{D}$ −23.5° ($CHCl_3$); β-heptaacetylisoprimeverose, m. 107–10°, $[\alpha]_{20}^{D}$ 82.3° ($CHCl_3$); β-1-Me hexaacetylprimeveroside, m. 219–20°, $[\alpha]_{20}^{D}$ −37.0° ($CHCl_3$); β-1-Me hexaacetylisoprimeveroside, m. 123–4°, $[\alpha]_{20}^{D}$ 66.0 ($CHCl_3$); α-acetoprimeverose, m. 201–3°, $[\alpha]_{20}^{D}$ 72.3° ($CHCl_3$); α-acetochloroisoprimeverose, m. 158–60°, $[\alpha]_{20}^{D}$ 185.8° ($CHCl_3$); α-acetobromoprimeverose, m. 176–8°, $[\alpha]_{20}^{D}$ 96.5° ($CHCl_3$); and α-acetobromoisoprimeverose, m. 155.5–7.5°, $[\alpha]_{20}^{D}$ 186.3° ($CHCl_3$). The reductive capacity of free isoprimeverose lies between that of maltose and lactose, being nearer to the latter; 1 cc. 0.1 *N* $KMnO_4$ equals, according to Bertrand, 5.1 mg. of isoprimeverose. S. S. de Finály

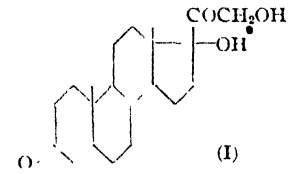
Isomerization of xanthophylls (addendum). L. Zechmeister, L. v. Cholnoky and A. Polgár. *Ber.* **72B**, 2039–40(1939); cf. *C. A.* **33**, 9308¹.—Strain's monograph, *Leaf Xanthophylls* (*C. A.* **33**, 3123³), has only now become available to the authors. Some of his observations are very similar to those of the authors and in part were made at an earlier date. But whereas the authors in their work laid the greatest stress on the complete reversibility of the transformations and on the study of catalytic influences and the theory of the isomerization, Strain sought principally (and successfully, on the basis of his extensive exptl. data) to prove the complexity of the leaf xanthophyll. C. A. R.

Desoxycholamine. Wm. T. Caldwell. *J. Am. Chem. Soc.* **61**, 3584–5(1939).—Desoxycholyl hydrazide (22 g.) in 67 cc. *N* HCl, and 400 cc. H_2O, treated with 400 g. ice and 4.2 g. $NaNO_2$ in 50 cc. and the pressed wet cake of azide gently heated with 210 cc. glacial AcOH to 45–60°, the product made alk. with KOH, the ppt. dissolved in EtOH-KOH, pptd. with H_2O and crystd. from MeOH, give 3 g. of *desoxycholamine*, with 1 mole of MeOH, m. above 70°; without MeOH, m. 158–9°; *HCl salt*, m. 306° Vanghelovici (private communication) reports a similar compd m. 118° (HCl salt, m. 247°). The 2 compds. are probably stereoisomers; epimerization may occur during the alk. hydrolysis used in the Curtius degradation. C. J. West

Sterols. XIX. Sterol of Semen coicis. Satoru Kuwada and S. Yosiki. *J. Pharm. Soc. Japan.* **59**, 560–6(in German, 203–4)(1939); cf. *C. A.* **33**, 8209².—The ether ext. of *Semen coicis* gave after hydrolysis a non-saponifiable compd., m. 90–110°; 3,5-dinitrobenzoate (I), $C_{36}H_{52}N_2O_6$, m. 215–16° (cor.), $[\alpha]_D^{18}$ −7.3° (in $CHCl_3$). Hydrolysis of I gave sitosterol (II), $C_{29}H_{50}O$, m. 138.5° (cor.), $[\alpha]_D^{19}$ −19.5°. II forms the following derivs.: acetate, $C_{31}H_{52}O_2$, m. 124–5° (cor.), $[\alpha]_D^{19}$ −37.2°; benzoate, $C_{36}H_{54}O_2$, m. 147–9°, $[\alpha]_D^{23}$ −14.7°. Catalytic reduction of II with Pt oxide gave sitosterol, $C_{29}H_{52}O.0.5H_2O$, m. 140.5–2.5° (cor.), $[\alpha]_D^{23}$ 23.5°. 3,5-Dinitrobenzoate of phytosterol (Schuchardt), $C_{36}H_{52}N_2O_6$, m.

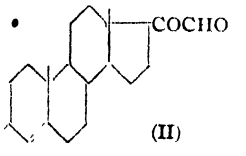
211–12° (cor.), $[\alpha]_D^{25}$ −14.0°, did not depress the m. p. of I. Phytosteryl *m*-dinitrobenzoate gave after hydrolysis a compd., m. 140.5° (cor.), $[\alpha]_D^{25}$ −35.6°. 3,5-Dinitrobenzoate of phytosterol (Merck), $C_{36}H_{52}N_2O_6$, m. 209–10° (cor.), $[\alpha]_D^{25}$ −13.2°, did not depress the m. p. of I.

F. I. Nakamura



Sterols. LXXVI. Oxidation and reduction products of equilenin. Russell E. Marker and Ewald Rohrmann. *J. Am. Chem. Soc.* **61**, 3314–17(1939); cf. *C. A.* **34**, 4423.—Reduction of equilenin (I) with the Adams catalyst in Et_2O-EtOH at 3 atm. H pressure and 25° for 15 hrs. gives α-dihydroequilenin (II), m. 245–7°; reduction of II in acidified EtOH gives 5,7,9-estratrien-17(α)-ol (III), m. 144–6° (cf. Ruzicka, Muller and Morgeli, *C. A.* **33**, 1337[2]); this indicates that the HO group at C-17 is of the α-configuration. III and CrO_3 in AcOH, on standing 1 hr. at 25°, give *5,7,9-estratrien-17-one*, m. 107–9°; *oxime*, m. 203–5° (decompn.). The diketone $C_{18}H_{16}O_2$ (*C. A.* **33**, 8621[6]) is believed to be *3-desoxy-11-ketoequilenin* (IV); reduction in acidified EtOH of 250 mg IV gives 150 mg. of III; III *acetate*, m. 102–3°; catalytic reduction of IV in Et_2O-EtOH gives the *compd.* $C_{18}H_{20}O_2$, m. 209–12° (the 2 CO groups appear to be reduced to HO groups); Clemmensen reduction with Zn gives the *compd.* $C_{18}H_{18}O$, m. 156–8° (monoketo compd.), whereas amalgamated Zn gives desoxyequilenin, $C_{18}H_{20}$, m. 73–5°. The CO group at C-11 is probably introduced during the CrO_3 oxidation, inasmuch as I acetate with CrO_3 in AcOH at 25° for 5 hrs. yields a product which appears to be *11-ketoequilenin acetate*, $C_{20}H_{18}O_4$, m. 195–7°; *monosemicarbazone*, m. 238–41° (decompn.); thus IV may be formed by the oxidation of 3-desoxydihydroequilenin and therefore this may be present in mares' pregnancy urine. I reacts readily with $ClCH_2CO_2Et$ and EtONa in EtOH to give *equilenin-3-oxyacetic acid*, m. 233–6°; *Et ester*, m. 141.5–3°; *Me ester*, m. 180–2°; catalytic reduction gives III. **LXXVII. The oxidation of pregnane-3,4,20(α)-triol and of coprostane-3,4-diol.** Russell E. Marker, Eugene L. Wittle, Louis Plambeck, Jr., Ewald Rohrmann, John Krueger and Paul R. Ulshafer. *Ibid.* 3317–20.—4,20-Diacetoxypregnan-3-one (I) (1.7 g.) on catalytic reduction in Et_2O-EtOH gives 1.4 g. 4,20-diacetoxypregnan-3-ol (II), unsharp m. p. and gives only a slight ppt. with digitonin (III); CrO_3 gives a quant. yield of I; hydrolysis with EtOH-KOH gives *pregnan-3,4,20(α)-triol* (IV), m. 184°, gives no ppt. with IV; *triacetate*, m. 181°. Reduction of I with (iso-PrO)$_3$Al also gives IV, characterized as its acetate. Oxidation of IV with CrO_3 in AcOH gives *pregnan-20-one-3,4-dicarboxylic acid* (V), m. 216° (*oxime*, m. 238°); V gives a m. p. lowering of 20° with the 2,3-diacid of allopregnan-20-one (*C. A.* **31**, 7870[9]) and m. 180–220° with the 2,3-diacid of pregnan-20-one (m. 281°) (VI); di-Me ester of VI, m. 87°. IV and $Pb(OAc)_4$ in AcOH (room temp. for 24 hrs.) give *pregnan-20(α)-ol-3,4-dicarboxylic acid*, m. 231°; CrO_3 oxidation gives V. 4-Bromocoprostanone and AcOK in AcOH, refluxed 2 hrs., give *4-acetoxycoprostanone*, m. 149°; catalytic reduction and hydrolysis give *coprostane-3,4-diol*, m. 185–8°; CrO_3 oxidation gives *coprostane-3,4-diacid*, m. 217°; *di-Me ester*, m. 74°; this is different from the dicarboxylic acid obtained by direct oxidation of coprostanone. Thus, the point of cleavage of ring A of the sterols on oxidation is highly dependent on the nature of the group attached to C-17, even though this group is far removed from the point of oxidative attack. The greater part of the oxidative fission of 3-substituted derivs. of the coprostane configuration (except those of the bile acid series) takes place at the 2,3-bond rather than at the 3,4-bond as has been generally assumed. **LXXVIII. Sterols from sow pregnancy urine.** Russell E. Marker and Ewald Rohrmann. *Ibid.* 3476–7.—Sow pregnancy urine differs from other pregnancy urines studied in that the pregnanediols appear to be absent. Pregnan-3(α)-ol-20-one (I), allopregnan-3(β)-ol-20-one, cholesterol and the urinary hydrocarbon ($C_{28}H_{58}$) were isolated. The epi-ketone fraction remaining after the removal of I yields an oxime which appears to be identical with androsterone. This lends further support to the theory that these products are derived from the adrenal compds. There appear to be other 3(β)-sterols present in the sow pregnancy urine but these could not be isolated from the quantity of urine studied. No apparent differences were observed in urine collected during the 2nd month and during the last month of pregnancy. **LXXIX. Oxidation products of dihydrosarsasapogenin.** *Ibid.* 3477–9.—Dihydrosarsasapogenin was refluxed with Ac_2O for 30 min., the excess Ac_2O removed, the residue taken up in AcOH and the soln. heated at 90–5° and treated with CrO_3 in AcOH during 2 hrs., the soln. concd. to 100 cc. and pptd. with H_2O; the ppt. was taken up in Et_2O and washed with 3% NaOH; the Et_2O soln. was concd. and the product hydrolyzed with EtOH-KOH: this yields a neutral sirup and some HO lactone or sarsasapogenin, m. 200–1.5°; the NaOH washings yield the C_{22} keto acid, m. 285–7° (*C. A.* **33**, 5407[8]) and the C_{19} dibasic acid, m. 220–2° (*C. A.* **34**, 1412[2]); the *acetate anhydride* of the latter m. 202–3.5°. The Me ester of anhydrotetrahydrosarsasapogenoic acid was refluxed with Ac_2O and oxidized with CrO_3 as above, except that the reaction mixt. was heated 4 hrs. at 55–60° and 1 hr. at 80°; the residue from the Et_2O soln. (after washing with 3% NaOH) on hydrolysis gives anhydrosarsasapogenoic acid; the acid fraction gives the C_{22} keto acid and 3-hydroxyetiobilianic acid. This indicates that the Me ester acetate of sarsasapogenoic acid was formed in the oxidation and was in turn converted to the anhydro acid by the alkali treatment; in this reaction sarsasapogenoic acid could only have arisen from the oxidative opening of the oxide ring to yield a diketo compd., thus supporting the proposed formula for the acid (*C. A.* **33**, 7807[2]). **LXXX. Reactions of chlorogenin.** *Ibid.* 3479–82; cf. *C. A.* **33**, 4263[4].—Chlorogenin (I) resembles tigogenin more closely than it does sarsasapogenin in its various reactions involving the side chain. I shows little tendency to undergo isomerization with HCl in EtOH. Attempts to reduce I by the Clemmensen reaction were unsuccessful. Catalytic reduction of 7 g. of I in AcOH at 70° for 16 hrs. gives 5 g. of *dihydrochlorogenin* (II), m. 233–5°; II gives a ppt. with a 2% EtOH soln. of digitonin but does not react with Br or SeO_2; *tris-3,5-dinitrobenzoate*, m. 210–12°. Oxidation of II with CrO_3 in 80% AcOH gives *3,6-dehydroanhydrotetrahydrochlorogenoic acid*, m. 202–4°; *disemicarbazone*, m. 240° (decompn.); *Me ester*, m. 156.5–8°. I diacetate (III) yields a *Br compd.*, m. 200° (decompn.); reduction with Na and EtOH gives I. Catalytic reduction of desoxychlorogenin gives a dihydro deriv., m. 92.5–3.5°, identical with dihydrodesoxytigogenin. Oxidation of III with CrO_3 in AcOH at 90–5° gives the *lactone* of I, m. 250–51.5° (*diacetate*, m. 247–50°; *dibenzoate*, m. 278–80°), which is oxidized with CrO_3 at 25° to a *diketo lactone*, m. 213–5°; there also results a small amt. of an *acid* $C_{22}H_{34}O_5$, m. 221–6°. **LXXXI. Conversion of sarsasapogenin to pregnane-3(α),20(α)-diol.** *Ibid.* 3602–3.—Heating sarsasapogenin and Ac_2O at 200° gives *pseudosarsasapogenin*, $C_{27}H_{44}O_3$, m. 171–3°; mild oxidation with CrO_3 in AcOH gives a good yield of an *unsatd. diketone*, $C_{21}H_{30}O_2$, m. 201–3°; reduction with Na and EtOH gives pregnane-3(α),20(α)-diol, m. 236–9°.

C. J. West



Hydrolysis of dicholesteryl ether by acid clay. Tikataro Kawasaki. *J. Pharm. Soc. Japan* **59**, 418–23(in English, 268–70)(1939).—Bills (B. and McDonald, *C. A.* **20**, 2522) found that when cholesterol (I) was heated with floridin in CCl_4 soln. it was converted into dicholesteryl ether (II), which on further heating polymerized into a resinous product having antirachitic properties. Yoder (*C. A.* **31**, 1033[6]) assumed that the antirachitic substance prepd. by B. was cholesterilenesulfonic acid (III), which had been formed from I by the dehydrating and sulfonating action of SO_3 adsorbed at the surface of floridin. He obtained I and II by floridin treatment and concluded that II would be decompd. into I and cholesterilene, then the latter sulfonated. Hattori and K. (*C. A.* **31**, 6247[6]; **33**, 8622[1]) have shown that I in C_6H_6 soln. heated with activated Japanese acid clay was easily dehydrated into II and on prolonged heating an antirachitic substance was produced. The formation of II from I is so rapid that only a few min. boiling with acid clay is sufficient. But a com-

plete conversion of I to II does not take place, and a small portion of I remains unchanged even after many hrs. of boiling. The presence of unchanged I can be easily demonstrated by means of the chromatograph. The C_6H_6 soln. of I is refluxed with acid clay until the clay has become a darker purplish red color. The soln. after filtering off the clay is passed through an activated Al_2O_3 layer. On evapg. the filtrate, II is sepd. When the Al_2O_3 layer is extd. with MeOH, pure I is obtained. The above expt. shows that the dehydrating action of acid clay is not strong and an equil. is established between I and II. Inversely, it can be shown that II can be decompd. into I by acid clay. The C_6H_6 soln. of II (1.5 g.) is passed through an Al_2O_3 layer to remove I. Then the filtrate is boiled 10 min. with acid clay. After filtering off the acid clay, the filtrate is passed through the Al_2O_3 layer. On washing the latter with C_6H_6 or CCl_4, II is recovered unchanged. On extg. the Al_2O_3 layer with MeOH, 0.12 g. I is obtained, which gives a ppt. with digitonin and no depression of m. p. when mixed with a pure specimen of I. The above results show Y.'s statement is erroneous. I, isolated by Y., must have been formed by hydrolysis of II. The assumption that the antirachitic substance produced by floridin activation is cholesterilenesulfonic acid is deemed untenable as shown by Windaus from another angle. Nao Uyei

Constituents of the adrenal cortex and related compounds. XXVI. Proof for the membership of substance S in the 17(β)-series. T. Reichstein, C. Meystre and J. v. Euw. *Helv. Chim. Acta* **22**, 1107–13(1939); cf. *C. A.* 33, 6870[1].—Proof is given that the formula proposed for substance S (I) is correct. The mother liquor of I (18 mg.)

in 3 cc. MeOH was treated with 35 mg. HIO_4 in 3 cc. H_2O for 16 hrs. at room temp. The residue on evapn. was taken out with ether and the washed ext. was extd. with Na_2CO_3. Acidification with HCl and extn. with ether gave 10 mg. of crude acid which, on recrystn. from ether, yielded 2 mg. of *acid* (II), $C_{20}H_{28}O_4$, m. 232–40° (all m. ps. cor.). Methylation with CH_2N_2 in ether at 0°, filtration over Al_2O_3, elution with benzene-ether (1:1) and recrystn. from ether-pentane gave colorless needles of Me 3-keto-17(β)-hydroxy-4-etiocholenate (III), $C_{21}H_{30}O_4$, m. 216–18°, identical with the ester prepd. by oxidizing 10 mg. of Me 3(β),17(β)-dihydroxy 5-etiocholenate (*C. A.* **33**, 6870[1]), m. 232–6°, by refluxing for 24 hrs. in 0.8 cc. acetone and 2 cc. benzene with 100 mg. of freshly sublimed $Al(OCMe_3)_3$. The formation of II is in accordance with the presence of a dihydroxyacetone grouping in the side-chain. The alternative dihydroxyaldehyde grouping would give rise to 4-androstene-3,17-dione. Oxidation of 50 mg. of Me 3(β),17(α)-dihydroxy-5-etiocholenate (IV) (*C. A.* **32**, 2126[2]) according to Oppenauer (*C. A.* **31**, 3061[3]) by refluxing with acetone and $Al(OCMe_3)_3$ in benzene gave an oxidation mixt. partially purified by Girard's reagent T to give a keto ester (V), m. 182–5°, contg. 30–5% of the starting ester but distinct from III. Bromination of IV prior to oxidation with CrO_3 in AcOH and debromination with Zn also gave impure V. I has the assigned formula and accordingly belongs to the 17(β)-series. **XXVII. 3-Keto-4-androstenyl-17-glyoxal and related compounds.** H. Reichand T. Reichstein. *Ibid.* 1124–38.—Of the 5 known physiol. active pregnane derivs. isolated from the adrenal cortex, desoxycorticosterone (I) and its esters have shown the strongest activity. Substance S may also be active. The non-cryst. residues are more active than any identified cryst. constituent and, since this active constituent is difficult to isolate, attempts have been made to synthesize more active principles by modifying the side chain. The prepn. of 3-keto-4-androstenyl-17-glyoxal (II) from 21-chloro-5-pregnen-3-ol-20-one (III) (*C. A.* **32**, 581[3]), by the use of the excellently suitable method of Kröhnke and Börner (*C. A.* **30**, 6714[7]) in 2 distinct procedures, is described. A suspension of 9 g. 21-diazopregnenolone (*C. A.* **32**, 581[3]) in 100 cc. ether was treated with 15 g. dry HCl in 200 cc. ether and the washed and dried reaction mixt. was concd. The crude cryst. product was washed

with ether and the mother liquor was purified by chromatographic adsorption, giving a total yield of 7 g. III. Similar treatment of 0.9 g. 21-diazopregnenolone with 2 g. HBr in ether gave 600 mg. of pure *21-bromopregnenolone* (IV), m. 159.0–9.5°(all m. ps. cor.). Heating 2 g. III for 1 hr. on the steam bath with 14 cc. abs. pyridine gave 2 g. of *21-pyridinium-5-pregnen-3-ol-20-one chloride* (V), $C_{26}H_{36}ClNO_2$, m. 289–90°. Analogous procedures converted IV into the corresponding *bromide*, m. about 300° (decompn.). A chilled mixt. of 429.5 mg. V in 13.4 cc. alc. and 150 mg. *p*-$ONC_6H_4NMe_2$ was shaken with 1 cc. of *N* NaOH. The red soln. was dild. and the ppt. was recrystd. from dil. alc., yielding fine orange-yellow needles of hydrated *3-hydroxy-5-etiocholenoyl-N-(p-dimethylaminophenyl)-nitrone* (VI), $C_{29}H_{40}N_2O_3.H_2O$, m. 133–4°. A suspension of 430 mg. VI in ether was shaken out with 2 *N* HCl. Concn. of the washed and dried Et_2O layer gave hydrated crystals of *5-pregnen-3-ol-20-on-21-al* (VII), $C_{21}H_{30}O_3.H_2O$, m. 135–6°. Concn. of the mother liquor gave a high-melting form (VIII), m. 170°, probably a polymeric form of VII. Both VII and VIII gave the same *di-Me acetal* (IX), $C_{23}H_{36}O_4$, m. 109–11° (after sublimation at 0.01 mm. and 165°, followed by recrystn. from ether-pentane), m. 112–13° (after chromatography), $[\alpha]_D^{23}$ 39.1 ± 1°, $[\alpha]_{5461}^{23}$ 52.2 ± 1° (*c* 2.202 in MeOH). Both VII and VIII reduce NH_3-$AgNO_3$ and were further characterized by the formation of a *dioxime*, $C_{21}H_{32}N_2O_3$, m. 285–90°; *quinoxaline*, $C_{27}H_{34}N_2O$, m. 229–31°; and *dianil*, $C_{33}H_{40}N_2O$, m. 85–90°. Oxidation of 190 mg. IX by refluxing for 24 hrs. with 5 cc. acetone, 15 cc. abs. benzene and 415 gm. of freshly sublimed $Al(OCMe_3)_3$ and careful purification of the reaction products by chromatography and high vacuum sublimation gave 50 mg. of cryst. *4-pregnene-3,20-dion-21-al di-Me acetal* (X), $C_{23}H_{34}O_4$, m. 84–6°, $[\alpha]_D^{23}$ 170.3 ± 2°, $[\alpha]_{5461}^{23}$ 207.9 ± 3° (*c* 1.116 in acetone), ultraviolet absorption max. 244 mμ (in alc.). Hydrolysis of 100 mg. X at room temp. with 1 cc. AcOH and 1 cc. of 2 *N* HCl for 5 days, neutralization, sublimation in high vacuum at 150°, and recrystn. from ether yielded a small amt. of cryst. II, m. 230–40°. A mixt. of 5 g. III, 150 cc. of freshly distd. acetone, 450 cc. abs. benzene and 12.5 g. of freshly sublimed $Al(OCMe_3)_3$ was refluxed for 24 hrs., evapd. *in vacuo* and extd. with ether. The ext. was washed with dil. HCl, H_2O, Na_2CO_3 and H_2O. Acidification of the alk. ext. gave 0.5 g. of an impure *acid*, m. 297–9°, methylated by CH_2N_2 to *Me 3-keto-4-etiocholenate*, $C_{21}H_{30}O_3$, m. 170–4°, absorption max. 244 mμ, isomeric with a known ester (*C. A.* **32**, 947[3]). The dried neutral ext. was concd. and the recrystd. product was chromatographed and recrystd. from benzene-ether, yielding *21-chloroprogesterone* (XI), $C_{21}H_{29}ClO_2$, m. 203–5°, $[\alpha]_D^{24}$ 209.5 ± 6°, $[\alpha]_{5461}^{24}$ 255.2 ± 7° (*c* 1.007 in $CHCl_3$), converted by refluxing for 1 hr. with fused AcONa in AcOH to desoxycorticosterone acetate, m. 159–60°. Details for the prepn. of XI by stirring a mixt. of 200 mg. I and 200 mg. $CaCO_3$ in 4 cc. $CHCl_3$ with 200 mg. powd. PCl_5 at 0° are given. Oxidation of IV according to Oppenauer's procedure gave *21-bromoprogesterone*, $C_{21}H_{29}BrO_2$, m. 190–1°. Heating 1 g. XI for 1 hr. with 10 cc. abs. pyridine at 100° yielded 1.042 g. of colorless crystals of *21-pyridinium-4-pregnene-3,20-dione chloride* (XII), $C_{26}H_{34}ClNO_2$, m. 274–5° (decompn.). The corresponding *Br deriv.*, m.

265–8° (decompn.), was similarly prepd. A mixt. of 214 mg. **XII** and 75 mg. of *p*-$ONC_6H_4NMe_2$ in 6.7 cc. alc. was cooled to −10°, treated with 0.5 cc. of *N* NaOH and, after recooling for 5 min., with 4 cc. H_2O. The resulting orange-yellow *nitrone* was shaken with Et_2O and dil. HCl and the washed and dried Et_2O layer was concd. A good yield of difficultly crystallizable material was obtained which gave a poor yield of **II**, m. 103–6°, converted by HCl in MeOH to **X**. Physiol. tests of amorphous **II** according to the Everse de Fremery method gave a very pos. result with 2.5 mg. per day per rat from which it would seem that **II** is less active than corticosterone.

C. R. Addinall

Chemical studies on the poisonous substance of the toad. X. Chemical constitution of cinobufagin Kenji Kuwada. *J. Chem. Soc. Japan* **60**, 45–8(1939); cf. *C. A.* **32**, 9092⁸; **33**, 5861⁶.—Dissolve 0.9 g. cinobufagone, m. 234–bath for 1.5 hrs., then pour the contents in water and acidify with H_2SO_4 in order to obtain a ppt. Take this ppt. up in ether and dry with anhyd. Na_2SO_4, then remove the ether. Treat the residue with acetone-ether in order to obtain crystals of desacetylisocinobufagonic acid (**I**), m. 217° (yield 0.2 g.). Recrystn. from EtOH gives columns, m. 218–21°. **I** is sol. in dil. alkali and aq. $NaHCO_3$; **I** gives no color with alc. $FeCl_3$ and does not reduce Fehling soln. or Tollen's reagent. Dissolve 10 g. cinobufagin, m. 212–13° in 100 cc. 95% EtOH by heating, and heat to boiling in a mixt. of 100 cc. concd. HCl (d. 1.19) and 300 cc. 95% EtOH and boil for 5 min. Pour into a large amt. of water and take up the ppt. formed with $CHCl_3$ and dehydrate with Na_2SO_4. Yield of desacetylanhydrocinobufagin (**II**) 2.0 g., m. 226–8°. Recrystn. from EtOH gives light yellow plates, m. 227–9°; Ac deriv., colorless needles, m. 201–5°. Dissolve 2.0 g. **II** in 50 cc. glacial AcOH, reduce with H and Pd black at the rate of absorption of 630 cc. H in 2 hrs., remove the Pd by filtration, pour the filtrate into water and take the ppt. up in $CHCl_3$. Wash the $CHCl_3$ layer with water until it is no longer acid in reaction, shake with 2% aq. $NaHCO_3$, then dry with Na_2SO_4. Conc. the $CHCl_3$ to obtain octahydrodesacetylanhydrocinobufagin (**III**), m. 203–6° (yield 0.35 g.); recrystd. from MeOH, it m. 207.5–8.5°. Wash the aq. $NaHCO_3$ layer with $CHCl_3$ and acidify with H_2SO_4, then ext. with $CHCl_3$, wash the $CHCl_3$ layer with water and dehydrate with Na_2SO_4, then remove the $CHCl_3$. Recrystn. from MeOH gives 0.05 g. leaflets of dihydroxycholanic acid (**IV**), m. 144–7°. Dissolve 0.2 g. **IV** in 15 cc. glacial AcOH and add, while cooling with ice, 2.5 cc. of a soln. of 1.5 g. CrO_3 in 20 cc. water and 2.5 cc. concd. H_2SO_4, and let stand for 20 min. at room temp. Pour into water, take ppt. up with $CHCl_3$, wash the $CHCl_3$ layer with water, dehydrate it with Na_2SO_4, remove the $CHCl_3$ and obtain diketocholanic acid by addg. EtOH; columns, m. 191–5°, lowers the m. p. of 3,12-diketocholanic acid. Heat 0.07 g. **III** in a mixt. of 2 cc. anhyd. AcOH and 0.3 g. anhyd. AcONa for 2 hrs. on the water bath, pour into water and take the crystals up with ether. Wash the ether layer with water, then dry it with Na_2SO_4. Remove the ether and recrystallize the residue from MeOH to obtain the mono-Ac deriv. of **III**, needles, m. 207–9°.

Infrared studies of porphyrin mol. (Vestling, Downing) **3**. Thermal data on org. compds. (Richardson, Parks) **2**. Isomerization of C_4H_{10} and their equil. ratios (Moldavskii, Nizovkina) **2**.

Oxygenated organic compounds. Nicholas A. Milas (to Research Corp.). Brit. 508,526, July 3, 1939. Compds comprising phenols, glycols, aldehydes, ketones, quinones and carboxylic acids are produced by treating unsatd. org. compds., which may be aromatic hydrocarbons, unsatd. hydroaromatic compds., unsatd. terpenes, other compds. contg. an ethylene linkage and compds. contg. an acetylenic linkage, with a soln. of H_2O_2 in a nonaq. solvent, e. g., *tert*-BuOH, *tert*-AmOH, nitrites, ethers, in the presence of a catalyst consisting of an oxide of a metal other than Os that assumes various valencies, e. g., Ru, V, Cr, Mo. Reactions of the following types may be effected: (1) a monosubstituted ethylene $RCH.CH_2$ yields a glycol $RCH(OH)CH_2OH$, which by further oxidation yields an aldehyde RCHO and CH_2O; further oxidation to an acid RCOOH and HCOOH may follow, (2) a disubstituted ethylene $RR'C:CH_2$ yields a glycol $RR'C(OH)CH_2OH$ from which, by further oxidation, a ketone RR'CO and CH_2O are obtained; further oxidation of CH_2O to HCOOH may follow, (3) a trisubstituted ethylene RR'C:CHR'' yields a glycol RR'C(OH)CHR''OH, from which, by further oxidation, a ketone RR'CO and an aldehyde R''CHO are obtained; oxidation of the aldehyde to an acid R''COOH may follow, (4) a tetrasubstituted ethylene RR'C:CR''R''' yields a glycol RR'C(OH)CR''R''', which, by further oxidation, yields ketones RR'CO and R''R'''CO, (5) C_2H_4 yields ethylene glycol from which CH_2O and HCOOH may be obtained by further oxidation, (6) a monosubstituted acetylene RC:CH may yield (a) a hydroxy aldehyde RCH(OH)CHO, produced by isomerization of the glycol RC(OH)CHOH, or (b) a keto aldehyde RCOCHO, produced by dehydration of the glycol $RC(OH)_2CH(OH)_2$; further oxidation of the aldehydes may yield the corresponding hydroxy and ketonic acids RCH(OH)COOH and RCOCOOH, (7) a disubstituted acetylene RC:CR' may yield (a) a hydroxy ketone RCH(OH)COR', produced by isomerization of the glycol RC(OH)CR'OH, or (b) a diketone RCOCOR', produced by dehydration of the glycol $RC(OH)_2CR'(OH)_2$, (8) C_2H_2 yields, by isomerization or dehydration of intermediately formed glycols, glyoxal and glycolaldehyde, from which, by further oxidation, glycolic acid and $(COOH)_2$ may be obtained, (9) cyclohexane yields 1,2-cyclohexanediol, which yields adipaldehyde and adipic acid on further oxidation, and (10) C_6H_6 yields PhOH, toluene yields *o*- and *p*-cresol, $C_{10}H_8$ yields 1,2- and 1,4-naphthoquinone, α-naphthol and phthalic acid, anthracene yields anthraquinone and phenanthrene yields phenanthraquinone.

Production of olefin oxides. Ray M. Carter (to U. S. Industrial Alc. Co.). U. S. 2,177,361, Oct. 24. An arrangement of app. is described, and a method for causing an olefin such as C_2H_4 and an O-contg. gas to react in the presence of an active Ag catalyst which involves sepg. the olefin oxide from the gases after contact with the catalyst by selective absorption with an aq. soln. under conditions which will cause moisture to be added to the gases from which the olefin oxide is sepd., recycling at least a part of the effluent gas from the sepn. and mixing it with make-up O-contg. gas, and removing moisture from the resultant gaseous mixt. before it comes into contact with the catalyst until the moisture content of the gaseous mixt. is less than that indicated by a dew point below −10°. Cf. *C. A.* **33**, 7312⁸.

3-Hydroxybiphenylene oxides. Karl Zahn and Kurt Schimmelschmidt (to General Aniline Works). U. S. 2,172,572, Sept. 12. A process of prepg. 3-hydroxybiphenylene oxides comprises heating compds. of the general formula 1,4-$(HO)_2$-2-(2-Cl-3-X_1-4-X_2-5-X_3-6-X_4C_6)C_6H_1, where X_1 and X_4 stand for H or Cl, X_2 stands for H, methyl, Cl, methoxy or amino, and X_3 stands for H, methyl, Cl or methoxy, at least three X's being H, the fourth X being other than H, with an agent having an alk. action selected from the group consisting of alkali metal hydroxides and alkali metal carbonates to a temp. of about 170–270°. Cf. *C. A.* **34**, 636³.

Olefin glycols. I. G. Farbenindustrie A.-G. Brit. 508,543, June 29, 1939. Addn. to 501,015 (*C. A.* **33**, 5870⁴). These, of formula $R^1R^2C(OH)CH:CHC(OH)R^3R^3$, in which R, R^1, R^2 and R^3 are H or identical or different alkyl, cycloalkyl, aralkyl or aryl groups, are prepd. by treating in aq. alk. soln. with Zn the corresponding acetylene glycols, which may be obtained by the process of Brit. 508,062 (*C. A.* **34**, 447⁴). Examples are given of the prepn. of *cis*- and *trans*-butene-1,4-diol from butyne-1,4-diol with use of NaOH and electrolytic Zn dust. N bases may also be used as the alk. agent as described in Brit. 504,957 (*C. A.* **33**, 7815⁴). Org. solvents,

e g., aliphatic alcs., ketones or dioxane, may be added to the reaction mixt.

Peroxidic products (germicides, fungicides, bleaching agents, and intermediates for organic syntheses). Nicholas A. Milas (to Mass. Institute of Tech.). U. S. 2,176,407, Oct. 17. Various alcs. are treated with H_2O_2 in highly concd. aq. soln. (suitably a 30% soln. with conjoint use of a water-abstracting salt such as anhyd. Na_2SO_4 or $CaSO_4$), details being given of the treatment of *tert*-Bu alc., the methyl ether of diethylene glycol, *tert*-Am alc., EtOH, *sec*-butanol, monoethyl ether of ethylene glycol, monomethyl ether of ethylene glycol, diethylene glycol, ethylene glycol, iso-PrOH, benzyl alc., cineol, cyclohexanol, 4-methylcyclohexanol, and tetrahydrofurfuryl alc.

Recovering allyl alcohol from wood-spirits residue. Edgar C. Britton and Gerald H. Coleman (to Dow Chemical Co.). U. S. 2,176,055, Oct. 17. Wood-spirits residue is treated with HCl at a temp. below 75° (suitably 55–65°) whereby the allyl alc. present in the residue is preferentially reacted upon, forming allyl chloride as substantially the only aliphatic chloride present, and the allyl chloride is sepd. by distn. and heated with an aq. alkali soln. to form allyl alc.

Hydroxy aliphatic esters. Benjamin T. Brooks (to Standard Alc. Co.). U. S. 2,176,201, Oct. 17. For producing isomeric hydroxypropionic esters or other esters of org. acids contg. a hydroxyl group, reaction is effected between Me formate or other ester of a hydroxy lower mol. wt. satd. fatty acid and an aliphatic alc. contg. not more than 5 C atoms (suitably MeOH, at 100–140° under pressure).

Alcoholysis of glycerides. Virgil L. Hansley (to E. I. du Pont de Nemours & Co.). U. S. 2,177,407, Oct. 24. For the production of an ester, reaction is effected between a fatty acid glyceride such as palm oil or coconut oil and a monohydric aliphatic alc. such as MeOH or EtOH at a temp. of not less than 175° (suitably about 200° and under a corresponding pressure).

Dehydrogenating secondary hydroxy compounds, as in producing ketostearyl acetate from 1,12-octadecanediol and acetic anhydride. Benjamin W. Howk and Wilbur A. Lazier (to E. I. du Pont de Nemours & Co.). U. S. 2,173,114, Sept. 19. A dehydrogenation process for the conversion of secondary carbinol groups to ketonic groups comprises contacting a compd. of the general formula, $RCH(OH)(CHY)_xCH_2OR'$ in which R is a simple or substituted alkyl or aryl radical, R′ is H or an alkyl, aryl or acyl radical, and x is a number from 0 to 20, inclusive, and Y is H, a hydroxyl radical, an alkyl radical, or an aryl radical, in the liquid phase at a temp. between 50° and 400° with a metal of the eighth group of the periodic table, such as Ni, on kieselguhr. Various reactions are described.

Polyamides. Ralph A. Jacobson (to E. I. du Pont de Nemours & Co.). U. S. 2,176,074, Oct. 17. Polyamides which may be used in coating, molding or fiber-forming compns. are obtained (suitably by heating in alc. under pressure) from substantially solely bifunctional polyamide-forming reactants (such as phoronic acid and decaethylenediamine) at least one of which contains a lateral substituent in the chain of atoms sepg. the amide-forming groups, the amide-forming groups being attached to aliphatic C atoms and the lateral substituent being an ether or thioether group. Several examples are given. Cf. *C. A.* **34**, 7788.

Acetylenic carbinols. Thomas H. Vaughn (to Union Carbide and Carbon Research Laboratories, Inc.). U. S. 2,175,581, Oct. 10. For producing an acetylenic carbinol such as 3-methyl-1-butyn-3-ol, an acetylenic glycol such as 2-butyne-1,4-diol is pyrolyzed (as by distg. in the presence of K_2CO_3) and the acetylenic carbinol produced is recovered. Cf. *C. A.* **33**, 7815.

Mercapto aryl thiazoles. Wm. E. Messer (to U. S. Rubber Products, Inc.). U. S. 2,176,593, Oct. 17. A method of production is employed which may involve treating in alc. soln. at least 2 moles of an alkali salt of trithiocarbonic acid with at least one mole of *o,o*′-diaminodiphenyl disulfide, to form an alkali salt of mercaptobenzothiazole, evapg. the alc., removing free S after pptn. of the same from an aq. soln. of the salt, and subsequently recovering the mercaptobenzothiazole after pptn. of the same on acidification of the aq. soln. of the salt.

Imidazolines. Georg Kranzlein, Herbert Bestian and Walther Schnurr (to I. G. Farbenind. A.-G.). U. S. 2,176,843, Oct. 17. See Brit. 492,812 (*C. A.* **33**, 1761).

Epichlorohydrins. Wm. Engs and Alasdair W. Fairbairn (to Shell Development Co.). U. S. 2,177,419, Oct. 24. A process for the production of an epichlorohydrin involves bringing a dichlorohydrin into contact with an excess of a basic metal hydroxide such as $Ca(OH)_2$ in the presence of water at a temp. not above about 60° for a time sufficient to effect substantially complete conversion of the dichlorohydrin to the corresponding epichlorohydrin and recovering the latter by flash distn. with live steam at a pressure at least equal to atm. pressure so as to avoid any substantial loss due to hydration and hydrolysis reactions.

Isobutylene polymers of high molecular weight. Lewis A. Bannon (to Standard Oil Development Co.). U. S. 2,176,194, Oct. 17. An arrangement of app. is described, and a method for the production of a high mol. wt. polymer by polymerizing isobutylene by the action of B fluoride in the presence of an inert volatile diluent, such as C_2H_4 and iso-C_4H_8, and low polymers of the type of dimer and trimer, which involves sepg. the diluent from the high mol. wt. polymer, and recycling the diluent to the reaction chamber after removing the low mol. wt. polymers from it.

1-Amino-2,4-dibromoanthraquinone compounds. Henry R. Lee and David X. Klein (to E. I. du Pont de Nemours & Co.). U. S. 2,169,196, Aug. 8. 1-Amino-2,4-dibromoanthraquinone is prepd. by treating 1-amino-2-anthraquinonesulfonic acid with Br in an aq. soln. and is obtained in readily filterable form by heating the treated materials to 70–80° for 1 hr. Various similar dibromination reactions are also described or mentioned, as for the production of a 1-amino-2,4-dibromoanthraquinone carrying in one of the positions 5 and 6 a radical of the class consisting of —OR, —OR′OH and OR′OR′OH, where R stands for an alkyl radical contg. not more than 2 C atoms and where R′ in each case stands for an alkylene radical contg. not more than 2 C atoms.

Alkylolaminomethylene compounds. Jean G. Kern (to National Aniline and Chemical Co.). U. S. 2,169,736, Aug. 15. Compds. of the general formula $(HOR_1N(R_2)C(R_3)(R_4)OSO_2)_xAm$, where R_1 represents an alkylene, cycloalkylene, hydroxyalkylene or polyhydroxyalkylene radical; R_2 represents a member of the group consisting of hydrogen, alkyl and cycloalkyl radicals, and the radical $HO\text{-}R_1$; R_3 represents H or an alkyl radical; R_4 represents H or an alkyl radical or, only when R_4 represents H, aryl radicals; Am represents H or a metal atom; x is an integer which equals the valence of Am; and z is an integer less than 3, may be prepd. from primary or secondary alkylolamines by reaction with a hydroxymethylene sulfite or sulfoxylate derived from an aldehyde or a ketone. Details are given of the production of: Na monoethanolaminomethylene sulfite; Na diethanolaminomethylene sulfite; monoethanolaminoethylidene K sulfite; Na *N*-methylethanolaminomethylene sulfite; monoethanolaminoisopropylidene Na sulfite; diethanolaminoisopropylidene Na sulfite; monopropanediolaminobenzal Na sulfite, and related compds. These compds. are suitable for use as *intermediates in making other compds.* and as *dye assistants*. U. S. 2,169,737 relates to *insecticides* and *dye intermediates* of the general formula $(ArN{:}NN(R_1OH)C(R_2)(R_3)OSO_2)_xAm$ wherein Ar represents the aromatic residue of a diazotizable aromatic amine; R_1 is the same as given above; R_2 represents H or an alkyl group; R_3 represents H or an alkyl group or, when R_2 represents H, an aryl group; Am represents H or a metal atom; and x is an integer equal to the valence of Am, which may be obtained from compds. such as those described in U. S. 2,169,736 by reaction with diazonium salts such as those derived from aromatic amines of the benzene, naphthalene, anthraquinone, and carbazole series, for instance, the diazonium salts of *m*-chloroaniline, 2-methyl-5-chloroaniline, 2,5-dichloroaniline, 2,5-dichloro-4-methylaniline, 2-methoxy-5-chloro-

aniline, 2-methyl-4-nitroaniline, 3-nitro-4-methylaniline, 2-amino-4-methoxy-5-benzoylamino-1-chlorobenzene, 4-chloro-4'-amino-2',5'-diethoxyazobenzene, bianisidine, benzidine, 2,5-dimethoxy-4-(4'-methylbenzene-1'-sulfonylamino)aniline, 4,4'-diaminodiphenylamine, 4-amino-4'-methoxydiphenylamine, 4-amino-3-methoxydiphenylamine, 2-methoxy-5-chloro-4-benzoylaminoaniline, 2-methyl-5-methoxy-4-benzoylaminoaniline, 2,5-dimethoxy-4-benzoylaminoaniline, 2-chloro-5-methoxy-4-benzoylaminoaniline. The diazoamino compds. produced are valuable *dye intermediates*, especially in compns. contg. alkali metal salts of coupling components, since they exhibit an increased stability over the simpler forms of the diazo compds. as for example the nitrosamines, from which they are produced.

Compounds of the ceranthrene and cerbianthrene series. Heinrich Hopff and Karl Heymann (to General Aniline Works). U. S. 2,176,421, Oct. 17. Compds. of the ceranthrene or cerbianthrene series are produced by the reaction on compds. of the ceroxonols or ceroxenols with nascent H produced in an alk. medium until compds. practically insol. in alkali are obtained.

Oxo compds. of the polyhydrocyclopentanophenanthrene series. Schering A.-G. Brit. 508,072, June 22, 1939. These are prepd. by oxidizing compds. of the formula $R(HO)X\,CR'R''$, where X is a polyhydrocyclopentanophenanthrene residue, R is H or a hydrocarbon residue and R' and R'' are H and (or) hydrocarbon residues, e. g., alkyl, aryl, aralkyl or cycloalkyl. Nuclear double bonds are protected during the oxidation by the addn. of halogen or H halide. Starting materials may be obtained by the action of unsatd. metal org. compds. according to Brit. 467,790 (*C. A.* **31**, 8835[8]) on compds. of the polyhydrocyclopentanophenanthrene series contg. keto groups. If R in the above formula is H, aldehydes are formed by mild oxidation and carboxylic acids by more vigorous oxidation. Alternatively, the aldehydes first produced may be further oxidized to carboxylic acids. The OH present on the ring C atom to which the unsatd. side chain is attached may be split off in the form of H_2O, e. g., by heating with acid anhydrides or by vacuum distn., to form a C to C double bond which, in turn, may be satd. by hydrogenation. In examples, (1) cholestanone is treated in Et_2O soln. with bromostyrene (I) in the presence of Li and the product is treated with O_3 to give a product with a strong aldehyde reaction; this is treated further with CrO_3 to give the corresponding hydroxy carboxylic acid, and (2) estrone acetate is treated with I in Et_2O soln. in the presence of Mg and the 17-styryl-3,17-estradiol so produced is ozonized in $CHCl_3$ soln. to give 3,17-estradiol-17-carboxylic acid.

Solid diazonium double salts containing cobaltous chloride. Ferdinand Keller (to General Aniline Works). U. S. 2,175,807, Oct. 10. Solid salts of the general formula $\{R[N(:N)Cl]_n\}_m.CoCl_2$, where n and m stand for one of the numbers 1 and 2, the sum of $n + m$ being always 3, and R stands for a radical of the benzene, naphthalene, diphenyl or anthraquinone series, being generally green cryst substances which are very stable and have a good soly., are produced by treating solns. of diazonium salts with $CoCl_2$ or other Co salt in the presence of Cl ions. Numerous examples with details are given.

Methallyl phosphates. Edgar C. Britton and Clarence L. Moyle (to Dow Chemical Co.). U. S. 2,176,416, Oct. 17. Colorless mobile liquids useful as solvents for various materials and as modifying agents in the polymerization of styrene, etc., are produced by reacting Na methallylate with P oxyhalides. Details are given of the production of: trimethallyl phosphate, dimethallyl ethyl phosphate, monomethallyl diphenyl phosphate, and dimethallyl mono-*o*-diphenyl phosphate, and mention is made of the possible similar production of monomethallyl dibutyl phosphate, dimethallyl crotyl phosphate, monomethallyl dinaphthyl phosphate, dimethallyl monobenzyl phosphate, etc.

Diphenyl *o*-chlorophenyl phosphite. Clarence L. Moyle (to Dow Chemical Co.). U. S. 2,170,833, Aug. 29. This compd., a colorless mobile liquid b_8 about 238–46° and having a sp. gr. of 1.159 is suitable for plasticizing cellulose derivs. and is made by heating *o*-chlorophenyl phosphorous acid dichloride with phenol and adding Na_2CO_3.

Nitriles. Otto Nicodemus and Otto Wulff (to I. G. Farbenind. A.-G.). U. S. 2,177,619, Oct. 24. For producing a nitrile such as oleic acid nitrile, a fatty acid free from hydroxy groups and contg. at least 8 C atoms per mol., such as oleic acid, or a volatilizable ester such as the methyl ester of such an acid, is passed, in the vapor phase together with NH_3, over a dehydrating catalyst such as Al oxide or silica gel at a temp. of 320–420°. Several examples with details are given.

Aromatic mercury salts of organic acids. Carl N. Andersen (to Lever Bros. Co.). U. S. 2,177,049, Oct. 24. A method of prepg. aromatic Hg salts, in which an aromatic Hg group is linked with an org. acid radical by replacement of the acidic H of the org. acid, involves treating, in an inert liquid such as water or alc., an org. acid the acidic H of which is linked through O, with an aromatic Hg sol. salt of a sol. acid in which the Hg is directly connected to a nuclear C of an aromatic structure in which none of the C atoms has direct linkage with any element other than H, C or Hg, the reacting aromatic Hg salt being of an acid weaker than the reacting org. acid and the latter forming an aromatic Hg salt that is less sol. under the reaction conditions than the reacting aromatic Hg salt and the reacting org. acid. Details are given of the production of: bis(phenylmercury) adipate, m. 202°; bis(phenylmercury) malate, m. 202°; phenylmercury salicylate, m. 158°; phenylmercury ethanesulfonate, which becomes of moist appearance at 182° and puffs up at 186°; phenylmercury gluconate, m. 162–4°; phenylmercury quininate, m. 207° (decompn.); phenylmercury 2-phenylquinoline-4-carboxylate, m. 204–8°; phenylmercury *o*-sulfamylbenzoate, m. 142–3°; phenylmercury α-naphthoate, m. about 109°; phenylmercury carboxylate of tyrosine, darkening at 150° and decompg. at 240°; and phenylmercury chlorobenzoate, m. 108–110°. Cf. *C. A.* **33**, 7493[9], 9555[6].

Organic acids from oxidation of coal, coke, etc. Henry C. Howard (to Carnegie Institute of Technology). U. S. 2,176,343, Oct. 17. A process for the sepn. and purification of the aromatic org. acids formed by the oxidation of coal, coke and carbonaceous substances, which contain at least one six-membered C ring with other C atoms attached thereto, consists in placing a soln. of an alkali metal salt of the acid in the middle compartment of a three-compartment diaphragm cell, placing distd. water in the end compartments and passing a current of electricity through the cell whereby the acid radical and the metal radical are caused to move in opposite directions to the end cells, and collecting the metal radical and the acid radical in the separate end compartments. A similar process may be used for the recovery of mellitic acid from NH_4 mellitate. App. is described.

Polyene carboxylic acids and esters. Richard Kuhn and Christoph Grundmann (to Winthrop Chemical Co.). U. S. 2,175,843, Oct. 10. An acyl deriv. of an oxalo compd. of an unsatd. carboxylic acid ester in which the oxalo radical is connected with a C atom having at least one H atom and standing in α-position to a doubly bound C atom, such as the acetyl deriv. of oxalo-1,3-hexadiene-1-carboxylic acid ethyl ester, is transformed, by the action of a mild reducing agent such as Al amalgam, into the corresponding dihydrogenated compd. and a further double bond is caused to form by splitting off of the acyl radical in the form of acid by heating, followed by sapon. of the ester obtained (suitably by use of aq.-alc. KOH soln. and HCl for the production of 2-methylhexatriene-1,6-dicarboxylic acid, m. 245–7°). Various similar reactions are described.

Apparatus for continuous solvent extraction of acetic or propionic acid, etc., from dilute aqueous solutions. Jack J. Gordon and John H. Zeigler (to Eastman Kodak Co.). U. S. 2,176,899, Oct. 24. Various structural and operative details.

Concentrating aqueous aliphatic acid solutions such as those of acetic acid. Campbell C. Hyatt, Jr. (to Eastman Kodak Co.). U. S. 2,176,500, Oct. 17. An arrangement of app. is described, and a process for concg. aq. materials

contg. at least one of the lower aliphatic acids by azeotropic distn. which comprises feeding the aq. solns., at least partially in a vaporous condition, to a distn. unit contg. withdrawing agent of 50–90% AmOAc and 10–50% AmOH, supplying and maintaining the quantity of AmOAc and AmOH in the unit insufficient to appear below the aq. feed, subjecting the materials in the unit to a distn. treatment whereby a distillate contg. AmOAc, AmOH and water is removed from the unit, recovering AmOAc and AmOH from the distillate and returning it to the upper part of the unit.

Glutamic acid. Geza Braun (to Standard Brands Inc.) U. S. 2,176,785, Oct. 17. See Brit. 501,542 (C. I. **33**, 6348[8]).

Mellitic acid. Bernard Juettner (to Carnegie Institute of Technology). U. S. 2,176,348, Oct. 17. Coal, coke, charcoal, graphite, a C black or pitch is treated with HNO_3 and vanadic acid (suitably refluxing) for 14 days followed by treatment with an alkali metal permanganate in an alk. soln. (suitably with further heating for 7 days). Various details of procedure are described.

Aliphatic acid anhydrides. Josef Losch, Felix Walter, Heinrich Behringer and Otto Schlöttig (to Akt.-Ges. fur Stickstoffdunger). U. S. 2,177,494, Oct. 24. For the production of an anhydride such as Ac_2O, an aldehyde such as AcH is treated with O or ozone (suitably under pressure at 12°) and the anhydride formed is isolated. Various catalysts may be used and numerous details are given.

Endothermic reactions such as acetic anhydride and ketene production from acetic acid. Henry Dreyfus. U. S. 2,176,419, Oct. 17. A current of gaseous or vaporous starting material such as HOAc vapor is preheated and the pressure on it is reduced to a substantial subatm. pressure by passage through a constriction under the action of a suction pump, and the pressure on the material in a reaction zone is maintained not substantially over 300 mm Hg. Under such conditions, formation of undesired by-products is restricted.

Ethylene from oil such as gas oil. John J. Grebe (to Theodor Nagel). U. S. 2,176,962, Oct. 24. A process of producing C_2H_4 from oil involves preheating the oil under superatm. pressure while maintaining it at a temp. slightly below its vaporizing temp. under the prevailing pressure, injecting all of the preheated liquid oil into a flowing superheated condensable vapor such as superheated steam which contains sufficient heat to flash-heat the preheated oil to about 700–870°, at which temp. all of the hydrocarbons of the oil are instantly decompd. to C_2H_4 and hydrocarbons of not more than 4 C atoms, and then immediately shock-cooling the resulting gaseous mixt. to below 540° to prevent polymerizing reactions forming gasoline hydrocarbons and to retain the hydrocarbons as C_2H_4 and other hydrocarbons of not more than 4 C atoms. An arrangement of app. is described.

Selective absorption of ethylene from gas mixtures. Rudolph L. Hasche (to Eastman Kodak Co.). U. S. 2,176,496, Oct. 17. App. is described, and a continuous process for absorbing C_2H_4 from a mixt. also contg. C_2H_2 with use of a H_2SO_4 absorbent which involves continuously passing the mixt. through a series of H_2SO_4 absorbents in a state of activity less than max. and then passing off the C_2H_4 and C_2H_2 materials through H_2SO_4 absorbent having a content of $EtHSO_4$ in the range of from about 30–65 mols. of C_2H_4 per mol. of H_2SO_4. Other olefins may be similarly absorbed.

Vinyl acetate, ethylidene diacetate, and homologous esters. Henry Dreyfus. U. S. 2,176,958, Oct. 24. For the production of at least one vinyl ester or ethylidene diester, such as vinyl acetate or ethylidene diacetate, an aliphatic acid such as HOAc is treated with C_2H_2 (suitably at about 200°) in the presence of a catalyst for the reaction such as $Zn(OAc)_2$ which has hydrating properties and in the presence also of a metal salt such as $K_2Cr_2O_7$ which is an oxidizing agent, the quantity of the metal salt being at least 2% of the wt. of the catalyst used. This salt serves to promote the desired reaction.

Pentachlorophenol. Edgar C. Britton and Francis N. Alquist (to Dow Chemical Co.). U. S. 2,176,417, Oct. 17. Hexachlorophenol is reduced with gaseous SO_2 in the presence of a lower aliphatic alc. as an inert solvent for the reactants (suitably in EtOH at 80° for 8 hrs.).

Epicholesterol and intermediates. Russell E. Marker (to Parke, Davis & Co.). U. S. 2,177,355, Oct. 24. A process for the prepn. of epicholesterol involves oxidizing a cholesterol halide such as the chloride to 7-ketocholesteryl halide with a strong oxidizing agent such as chromic acid, converting the halide into the corresponding 3-hydroxy compd. by hydrolysis with KOH after acetylation with fused KOAc, treating the 7-ketoepicholesterol produced with a hydrazine deriv. such as semicarbazide and causing the product to react with alkali alcoholate to obtain epicholesterol. Various details of procedure are described.

Preparing $\Delta^{5,6}$-3-chloroetiocholen-17-one. John Weijlard (to Merck & Co. Inc.). U. S. 2,176,113, Oct. 17. A process for the production of the chloro ketone $\Delta^{5,6}$-3-chloroetiocholen-17-one comprises reacting dibromocholesteryl chloride with chromium trioxide in glacial HOAc at a temp. of about 65° for about 4 hrs., raising the temp. to about 90° until the dibromocholesteryl chloride is completely dissolved, lowering the temp. to about 60–65° for about 4 hrs., and subsequently debrominating the oxidation product with Zn in glacial HOAc.

Adenine derivatives and their biological functions. Cecilia Lutwak-Mann. *Biol. Rev. Cambridge Phil. Soc.* 14, 399–419(1939).—A review of the distribution, isolation and properties of biologically interesting adenine derivs. and their position in relation to certain biochem. processes is given. 155 references. David E. Adelson

Cataphoretic measurements on solutions of visual purple and indicator yellow. E. E. Broda, C. F. Goodeve, R. J. Lythgoe and E. Victor. *Nature* **144**, 709(1939); cf. *C. A.* 33, 1772[7].—Quartz particles (2–5 μ) were suspended in a soln. of visual purple from Hungarian frogs, 0.01 *N* acetate buffer was added and the cataphoretic velocity was measured in a microcataphoretic cell first with ruby light and then white light. The isoelec. point of the visual purple was 4.47 pH units, that of the indicator yellow, 4.57. Other prepns. of visual purple gave the same shift on bleaching, the isoelec. points agreeing with the above by ±0.1 pH. The bleaching process of visual purple probably results in an increase in the no. of alk. groups (as NH_2) available for ionization. Ruth Berggren

A mechanism for the concentrating of potassium by cells, with experimental verification for muscle. E. J. Conway and P. J. Boyle. *Nature* **144**, 709–10(1939).—From the requirements of the osmotic, elec. and Donnan equil. equations are derived which describe the conditions inside and outside a special membrane permeable to ions such as K, chloride, bicarbonate, phosphate, etc., but not to ions such as Na, hexose esters, phosphocreatine, etc. Such a membrane in contact with ionic media, as blood plasma, will result in a high internal K concn. in equil. with a low external K concn. Certain relationships are deduced which are shown experimentally to apply to excised muscle. The original entrance of K into the cells and the relation of K interchanges to carbohydrate metabolism are briefly discussed. Ruth Berggren

Colloidochemical hydrolysis of proteins. III. S. I. D'yachkovskiĭ, G. V. Tumanovskaya and I. B. Rabinovich. *Colloid J.* (U. S. S. R.) **5**, 501–15(1939); cf. *C. A.* **29**, 4033[1].—An aq. soln. of egg albumin was re-

peatedly shaken with Et_2O and the emulsion sepd.; the "ether fraction" contained 40% of the albumin taken. In an analogous way a "benzene fraction" contg. 7% of the initial protein was obtained. The same treatment was also applied to casein. Different fractions gave different color reactions. Conductometric titration showed that both exts. bound 2.2 times as much HCl as the native albumin. The loss of wt. on heating is different for the native albumin and the exts. J. J. Bikerman

The effect of acids in the general meaning of the term on the activity of invertase. Walter A. Wisansky. *J. Am. Chem. Soc.* **61**, 3330-4(1939).—The data indicate that acids, in the general meaning of the term "acid," can retard the enzymic activity of invertase under conditions which purport to hold the degree of ionization of the enzyme const. (i. e., conditions such as const. ionic strength and const. pH). It is suggested that oxonium ion and acids in general may alter the activity of an enzyme by causing the rupture of intramol. H bonds in the enzyme protein. Such bond breaking may give modified forms of the enzyme with more internal degrees of freedom, possessing less catalytic activity. A. B. G.

Application of radioactive isotopes to the study of biochemical exchanges and transformations. J. K. Parnas. *Bull. soc. chim. biol.* **21**, 1059-93(1939).—A review in the form of an address. Bibliography appended. L. E. G.

Chemical reactions between electrolytes and proteins in the form of sols or gels. IV. Reactions with salts of the bivalent alkali earth cations, calcium and magnesium. Methods. E. J. Bigwood. *Bull. soc. chim. biol.* **21**, 1102-4(1939); cf. *C. A.* **34**, 3056. **V. Experimental results with calcium and magnesium cations.** *Ibid* 1105-16. Solns. of blood albumin or globulin in collodion bags and lumps of gelatin gel were immersed in solns. of $CaCl_2$, $MgCl_2$ or $MgSO_4$. If the protein mixt. was on the acid side of the isoelec. point the Donnan equil. rule was applicable in a qual. but not in a quant. sense. At the isoelec. point or on the alk. side the rule did not apply, too much of both cation and anion passing into the protein mixt. L. E. Gilson

Use of radioactive phosphorus in the study of glucolysis and fermentation. O. Meyerhof. *Bull. soc. chim. biol.* **21**, 1094-1101(1939); cf. *C. A.* **33**, 6555. L. E. Gilson

Intake and loss of radioactive cations by certain marine eggs. S. C. Brooks. *Proc. Soc. Exptl Biol. Med.* **42**, 557-8(1939).—Preliminary. L. E. Gilson

Effect of certain radioactive elements on the metabolism of cells. Matilda Moldenhauer Brooks. *Proc. Soc. Exptl. Biol. Med.* **42**, 558-9(1939).—Radioactive Na and K (as chlorides) had no effect on the O consumption of *Nitella*, *Elodea* or red blood cells *in vitro*. L. E. Gilson

Influence of light rays on coagulation of plasma and fibrinogen. Ludwig Pincussen. *Proc. Soc. Exptl. Biol. Med.* **42**, 614-17(1939). Both visible and ultraviolet irradiation retarded coagulation of plasma. On fibrinogen the effects were irregular. Graphs are shown. L. E. Gilson

Optical activity of biological material—a review. I, II. G. F. Gauze. *Biodynamica*, No. **52**, 1-10, 11-26(1939). E. H.

Enzymes defensive against the proteins of the endocrine glands in the serum of old animals. N. B. Medvedeva. *J. méd., Ukraine* **9**, 7-25(in French, 24-5)(1939).—The interferometric index of the serum changes only slightly when youths pass adolescence, but on passing to old age a definite increase is observed. The serum of adult animals contains no enzymes against endocrine gland proteins, but these enzymes were found in the serums of old animals in approx. 50% of the cases. The enzymes decomp. the proteins of the various endocrine glands in the following order of decreasing activity: testicular and ovarian, thymus, pancreatic, cortical suprarenal, medullary suprarenal, hypophyseal and thyroid. S. A. Karjala

Enzymic decomposition of polymeric carbohydrates. II. Some enzymes of the house fungus (Merulius lacrimans). Theodor Ploetz. *Z. physiol. Chem.* **261**, 183-8(1939); cf. *C. A.* **33**, 6361[1].—Press juice from *Merulius lacrimans* cultures after dialysis shows lichenase, β-glucosidase, maltase and cellulase. The latter was not demonstrable in month-old cultures but was present after 2 and 4 months. If EtOH and Et_2O are added to the exts. the β-glucosidase is pptd. at a lower concn. of added solvents than is lichenase. Cellulase requires the highest concn. for pptn. This behavior is exactly the reverse of the behavior of the same enzymes in *Aspergillus* exts. and *Helix pomatia* exts. Milton Levy

The estimation and distribution of cytochrome oxidase and cytochrome C in rat tissues. Elmer Stotz. *J. Biol. Chem.* **131**, 555-65(1939); cf. *C. A.* **32**, 7933[9], 7934[4].—In the detn. of cytochrome oxidase the enzyme is dialyzed from ground tissue and the rate of hydroquinone oxidation in the presence of an excess of pure cytochrome C is measured manometrically. Cytochrome C is partially isolated by quant. procedures and is detd. by manometric measurement of hydroquinone oxidation in the presence of a beef heart oxidase prepn. As little as 30 γ of cytochrome or 0.1 γ of cytochrome-Fe gives sufficient velocities for estn. and the reaction is uninfluenced by other colored substances since a specific enzymic reaction is employed. The distribution of these substances in normal tissues was detd. by these methods and their amts. in the various tissues run remarkedly parallel. Since an increase in either constituent could increase the efficiency of the cytochrome system kinetically, this may indicate a common pathway for their synthesis or perhaps a basically similar chem. structure. The significance of the cytochrome system to cellular respiration is briefly discussed. A. P. L.

Ultraviolet absorption spectra of cocarboxylase, thiamine and their reduction products. Joseph L. Melnick. *J. Biol. Chem.* **131**, 615-20(1939).—The absorption spectra maxima for thiamine and cocarboxylase are very similar at the same pH. Upon reduction of either there is at pH 4 a lowering of the extinction at the max. at 235 to 237 mμ, while the max. at 265-6 mμ is lowered only slightly but is shifted to 280 mμ; at pH 2.3 the band at 243 mμ is still present but it is lowered and not so sharp. A. P. L.

Oxidation-reduction potentials of the methemoglobin-hemoglobin system. John F. Taylor and A. Baird Hastings. *J. Biol. Chem.* **131**, 649-62(1939).—The oxidation-reduction titration curve of the methemoglobin-hemoglobin system at const. pH is not symmetrical, the slope of the curve indicating that the no. of electrons involved apparently varies from 1 toward 2 as the oxidation progresses. The variation of the midpoint potential with pH indicates that upon the oxidation of hemoglobin to methemoglobin, for each electron transferred there appears a univalent cation corresponding to an apparent dissocn. const. (K) of 2.2×10^{-7} (pK = 6.65). At pH 7, the potential of an equimolar mixt. of horse methemoglobin and hemoglobin is +0.139 v. at 30°. The use of a small amt. of an electromotively active dye system as mediator permitted the rapid attainment of equil. at the Pt electrode, the dyes used being selected on the basis of close correspondence between their E'_0 and that of the hemoglobin system at the pH of the expt. No theory of the oxidation of hemoglobin has been devised which accounts satisfactorily for the exptl. results obtained. Thirty-two references. A. P. Lothrop

The mechanism of cocarboxylase action. Kurt G. Stern and Joseph L. Melnick. *J. Biol. Chem.* **131**, 597-613(1939).—Thiamine is not a typical primary amine since it reacts with ketene to yield an *O*-acetyl rather than an *N*-acetyl deriv. and it does not readily give up its N when treated with HNO_2. It would seem, therefore, that pyruvic acid cannot be decarboxylated via the "Langenbeck-cycle" (*C. A.* **33**, 4984[6]), i. e., by combination with cocarboxylase to form a catalytically active substituted imino acid. Dihydrothiamine is completely devoid of any antineuritic activity in pigeons while dihydrococarboxylase, on the other hand, is just as active as the oxidized form both in the polyneuritic pigeon and in the yeast test system. These differences emphasize the importance of the

pyrophosphate group which probably serves as the link between the active group and the protein bearer to which it must be attached before it can undergo reversible oxidation-reduction which it apparently does in the course of its physiol. action. Neither dihydrothiamine nor dihydrococarboxylase is autoxidizable. Thirty-eight references.
A. P. Lothrop

Equilibria between calcium and purified globulins. Nancy Drinker, Arda Alden Green and A. Baird Hastings. *J. Biol. Chem.* **131**, 641–7(1939); cf. *C. A.* **29**, 1127[4]; **30**, 6026[2].—The combination between Ca and 4 purified globulin fractions prepd. from horse serum has been studied by use of the frog heart technique for the estn. of the Ca-ion concn. The law of mass action is applicable to the ionization of these Ca protein salts. The $pK_{Ca/Prot}$ values for the various globulins of serum examd. are as follows: pseudoglobulin 2.96, euglobulin P_I 2.70, euglobulin P_{II} 2.90, euglobulin P_{III} 3.13. The estd. amt. of Ca combined per g. of each protein, when the Ca-ion concn. equals 1.0 mM per l., for the 4 globulins are as follows, resp.: 0.021, 0.037, 0.005 and 0.086 mM. Changes in the proportions of different globulin fractions would lead to the binding of different amts. of Ca by the globulin fraction of serum as a whole and might assume special significance in hyperglobulinemia.
A. P. Lothrop

Action of hexokinase. Sadaya Iri. *J. Biochem.* Japan) **30**, 217–24(1939).—The production of lactic acid from glucose by muscle ext. in the presence of hexokinase might be a series of changes beginning with the synthesis of glycogen from glucose. Hexokinase alone cannot react with glucose. Monoiodoacetic acid inhibits the glycogen synthesis from glucose, which suggests the possible participation of oxidation-reduction reactions in the process.
S. Morgulis

Relation between oxidoreduction and tryptic and ereptic activities. Zyunzi Nagai. *J. Biochem.* (Japan) **30**, 225–31(1939).—The attempt was made to induce synthetic action by such extracellular proteolytic enzymes as trypsinkinase and erepsin but with no success. It was found, however, that the oxidation-reduction state of the protein mol. had a direct relation to the proteolytic activity. Mild oxidation with H_2O_2 of casein or lens protein increased its resistance to trypsin, while reduction with Na_2SO_4 or with a succinic acid-succinodehydrogenase system accelerated its digestion. The SH-group is regarded as of special importance and it is pointed out that heat-denatured protein with a stronger SH reaction is also more easily digested than the native protein. A further indication of a change in the protein mol. is the fact that its optical rotation is increased by oxidation and decreased by reduction. Hydrolysis of dipeptides by erepsin under different reduction-oxidation conditions was also tested, and the enzyme activity was increased by reduction and retarded by oxidation. The intestinal flora which keeps the digestive enzymes in a reduced state thus assumes physiol. significance.
S. Morgulis

Liver arginase. II. Arginase action during liver autolysis. Masaru Kaizyu. *J. Biochem.* (Japan) **30**, 265–9(1939); cf. *C. A.* **33**, 2583[2].—The arginase activity in autolyzing liver ceases at pH 5 and cannot be reactivated with $MnSO_4$. This is attributed to the probable destruction of its protein moiety by trypsin or pepsin. During autolysis at pH 7 or 7.6 the arginase activity, in the presence or absence of activator, is decreased either because of the cathepsin or peptonase and peptidase action. The arginase is practically unaffected when liver paste is kept in the refrigerator. If, however, the pH is adjusted to 5, the activity is definitely lowered but can be restored by means of $MnSO_4$. **III. Arginase action on acetyl-*l*-phenylalanyl-*d*-arginine.** *Ibid.* 271–5.—The acetylpeptide is markedly hydrolyzed by macerated pancreas. It is also definitely hydrolyzed by liver paste as detd. both by the increase in formol titratable acidity and urea formation. But purified arginase prepd. from beef liver hydrolyzes acetyl-*l*-phenylalanyl-*d*-arginine only slightly.
S. Morgulis

Effects of oxidation-reduction on yeast sucrase action. Ryozi Ito and Huzio Obo. *J. Biochem.* (Japan) **30**, 277–82(1939).—Changing the reduction-oxidation potential of the reaction system by means of oxidizing (H_2O_2, I_2) and reducing ($Na_2S_2O_4$, H_2S) agents retards or slightly accelerates the yeast sucrase action but certainly not at all in relation to the extensive changes in potential. The inhibition of sucrase activity by amines is not fully removed by reduction.
S. Morgulis

Studies on lipase. VI. Effects of oxidation-reduction on the hydrolysis by serum lipase and milk esterase. Riozi Ito, Sinkiti Kayasima and Kinsei Huzimi. *J. Biochem.* (Japan) **30**, 283–9(1939).—The reaction mixt. consisted of 0.5 cc. tributyrin, 3 cc. 0.5% gelatin, 2 cc. *M*/15 phosphate buffer pH 7.0 (for esterase) or 7.7 (for lipase), 1 cc. of the oxidation or reduction agent and 1 cc. enzyme prepn. The latter consisted of dild. (1:1) human serum (lipase) and of human milk (esterase). The control mixt. contained everything except the tributyrin. After incubation for 6 hrs., 0.5 cc. tributyrin was added to the control, and 25 cc. abs. alc. to each and well shaken. Of the clear filtrate 20.0 cc. was titrated with alc. 0.05 *N* KOH. Both the lipase and esterase activity were increased by reduction and retarded by oxidation. Lipase inhibited by atoxyl or quinine was somewhat activated by reduction. Milk esterase, which splits only simplest esters, is present in human milk but not in cow or goat milk.

VII. Alkali titration method for the determination of tissue esterase activity and results obtained by this method. Riozi Ito and Sinkiti Kayasima. *Ibid.* 291–5.—The enzyme prepn. is made by grinding 2 g minced tissue with 8 cc. water, using pure sand, and filtering through muslin. The rest of the detn. is carried out as related in preceding abstr. The lipolytic activity of the tissues depends upon the natural content of reducing substances (glutathione, ascorbic acid). The activity of ox or hog gastric lipase is relatively weak but rabbit or human gastric lipase is very strong and is present chiefly in the mucosa. Blood lipase may be mainly in the erythrocytes (ox) or in the serum (rabbit). Advanced cancer patients have a lower blood lipase activity than healthy persons. The esterase activity of various portions of the brain is practically the same.

Enzyme investigations during the drying of green tobacco. L. Bartá. *Z. Untersuch. Lebensm.* **78**, 322–7(1939).—Tests were made on the activity of catalase, peroxidase and phenolase during the drying of green tobacco leaves at room as well as at higher (to 70°) temps. In the green tobacco leaves catalase is almost entirely in the water-insol. form, peroxidase being the reverse. The catalase activity is highest at the tip and at the edges; the peroxidase activity is highest in the venous system of the leaves. The catalase activity decreases quickly during drying. The peroxidase activity first increases and then slowly decreases on drying, except when drying at high temps. in which case the activity quickly decreases. Phenolase is not detected in green leaves. In drying at room temp. a max. phenolase activity develops in 100 hrs. and remains unchanged to the end of the drying period; at high temps., however, the phenolase quickly decreases toward the end of the drying period
M. M. Piskur

Progress of the Biochemical Research Foundation of the Franklin Institute. Ellice McDonald. *J. Franklin Inst.* **228**, 695–717(1939).—A progress report covering the chem., phys., bacteriol. and other work being done.

Gastric carbonic anhydrase. Horace W. Davenport. *J. Physiol.* **97**, 32–43(1939).—Carbonic anhydrase is present in the parietal cells of the gastric mucosa of cats and rats. In cats the concn. of carbonic anhydrase in the parietal cells is 5 to 6 times higher than in the red blood cells; in rats it is about 3 times higher. It is present in the cells of the surface epithelium of the gastric mucosa. In cats its concn. in the surface cells is about $^1/_{10}$ of that in the parietal cells. There is no carbonic anhydrase in the chief cells of cats or rats. A small amt. is present in an unidentified type of cell in the pyloric antrum of the rat. E. D. Walter

Cell-free enzymic model of *l*-amino acid dehydrogenase (*l*-deaminase). A. E. Braunshtein and S. M. Bychkov. *Nature* **144**, 751–2(1939).—A cell-free enzymic system was found which deaminizes *l*-alanine at a fairly high rate under aerobic conditions with pyocyanine as autoxidizable H carrier. E. D. Walter

Mechanism of decomposition of hydrogen peroxide by catalase. D. Keilin and E. F. Hartree. *Nature* **144**, 787–8(1939); cf. *C. A.* **32**, 2550[1].—The decompn. of H_2O_2 by catalase is brought about by the successive reduction of the catalase Fe by the H_2O_2 and its reoxidation by mol. O. This is in contradiction to the view of Johnson and Schouwenburg (*C. A.* **34**, 4607), which was based on qual. tests with luminous bacteria. *Ibid.* 1091. E. D. Walter

Studies on proteins in liquid ammonia. V. Reaction of sodium in liquid ammonia with peptones and related substances. Clemmy O. Miller and Richard G. Roberts. *J. Am. Chem. Soc.* **61**, 3551–6(1939); cf. *C. A.* **32**, 7492[4]. -- Peptones are acidic in liquid NH_3 and liberate H when Na is added to them; they are more acidic than diketopiperazine but less acidic than proteins or amino acids. Silk peptones prepd. by digesting silk fibroin for 10 days pass through a min. acidity on the 2nd and 3rd days Peptones are more closely related to diketopiperazines than are proteins in their acid reactions in liquid NH_3; they react as if they contained relatively more diketopiperazines than do proteins. C. J. West

Ultracentrifugal analysis and stability in protein systems. Harold P. Lundgren and J. W. Williams. *J. Phys. Chem.* **43**, 989–1002(1939).—The sedimentation const., *S*, the diffusion const., *D*, and the Svedberg dissymmetry factor, f/f_0, of phycocyan and of hemoglobin and their dissocn. products were detd. Upon dissocn. of phycocyan a pronounced decrease in *S* is accompanied by little change in *D* and an increase in the ratio of major to minor axis from 4:1 to 8:1. When hemoglobin dissocs. a decrease in *S* accompanies an increase in *D* and f/f_0 remains const. Native thyroglobulin (I) in salt soln. sediments as a single well-defined protein. In salt-free solns. of protein concn. greater than 1.0% there is an equil. between I and a single well-defined slower sedimenting component (II). The equil. $I \rightleftarrows II$ is attained rapidly in alk. soln., but very slowly at pH = 7. The addn. of 0.02 *M* electrolyte to II rapidly transforms it to I. At protein concns. under 0.1% equil. is established between II and a third slower sedimenting protein. Denatured protein appears to arise from II. The transformation of I into II probably involves an unfolding of the protein mol. Analogous equil. are observed with thymus nucleohistone and antitoxic diphtheria pseudoglobulin. W. B. Keighton

Phenolphthalein as a test for gastrointestinal ulceration in the experimental animal. Ben Slutzky and Chas. M. Wilhelmj. *Am. J. Digestive Diseases Nutrition* **6**, 449–50 (1939).—In the attempt to evaluate the Woldman test (cf. *C. A.* **32**, 9127[9]) for gastrointestinal ulceration 37 detns. were made on normal dogs and on dogs known to have ulceration. There was no uniformity of results. Dogs with jaundice gave false pos. reactions. In 5 cases of acute surgical ulcers no phenolphthalein was found in the urine of 3 of the 5 dogs. Edward Eagle

Intravenous modification of the hippuric acid test for liver function. Armand J. Quick. *Am. J. Digestive Diseases Nutrition* **6**, 716–17(1939). Edward Eagle

Spectroscopic analysis of biological fluids for heavy metals. D. W. Armstrong and F. S. Brackett. *J. Ind. Hyg. Toxicol.* **21**, 448–60(1939).—Spectroscopic analysis for Pb, Mn and Hg in the body fluids, urine and blood are outlined. Lower limits for lead are ±0.03 mg./l. Evaluations should be based on 5 or more detns. A. L. Elder

A new procedure in adsorption and elution and its application to the isolation of urinary imidazoles. André Riegert. *Compt. rend. soc. biol.* **132**, 115–17(1939).—A filter tube is prepd. with a column of medicinal charcoal 4 cm. deep. A small amt. of 0.033 *M* phosphate buffer, pH 6.9, is filtered through the column, then the urine previously mixed with an equal vol. of the buffer soln., then more buffer soln. Uric acid, arginine, tyrosine, xanthine, guanine, creatinine, phenols and imidazoles are quantitatively adsorbed by the C; urea and mineral salts are not adsorbed. From the C a 2% aq. soln. of pyridine removes exclusively and quantitatively the imidazoles, i. e., histidine, histamine, imidazole and imidazolelactic acid. L. E. Gilson

Preparation of stable fibrinogen for study of streptococcal fibrinolysin. L. R. Christensen and L. R. Jones. *Proc. Soc. Exptl. Biol. Med.* **42**, 569–71(1939).—Method. L. E. Gilson

Preparation and assay of inhibitor of gastric secretion and motility from normal human urine. H. Necheles, Martin E. Hanke and Erich Fantl. *Proc. Soc. Exptl. Biol. Med.* **42**, 618–19(1939).—Preliminary report on methods. L. E. Gilson

Polarographic studies: quantitative separation of sodium and potassium. W. Kemula and M. Michalski. *Atti X° congr. intern. chim.* **3**, 419–27(1939)(in French).—For physiol. studies the time and technique required by known methods to carry out a quant. sepn. of Na from K are decidedly objectionable. Previous polarographic studies have encountered difficulties arising from the similar oxidation potentials of Na and K. The method is described for the examn. of urine. Here the pH and the presence of Mg^{++}, Ca^{++}, PO_4^{---} and colloidal org. matter presented difficulties and the first polarographic curves were unsatisfactory. Neutralization with $(CH_3)_4NOH$ improved the conditions but the accurate detn. of Na and K in urine contg. 10–30 mg. Na and 20–60 mg. of K was accomplished only after adopting the following procedure. (1) Take 10 ml. of urine in a 100-ml. vessel, add 10 ml. of water, heat to boiling and titrate the hot soln. with 0.1 *N* $Ba(OH)_2$ using phenolphthalein. This causes the pptn. of Mg^{++}, Ca^{++}, PO_4^{---} and SO_4^{--}. (2) Add 2 ml. of satd. $(NH_4)_2C_2O_4$ soln. and introduce CO_2 for 20 min. to ppt. all Ba^{++} and Ca^{++}, heat on the water bath for 30 min. to coagulate the ppt., filter and wash with hot water. (3) Evap. the filtrate to dryness, moisten the residue with HCl, heat to 300° to remove NH_4 salts and finally raise the temp. to about 550° in an elec. furnace. (4) Digest the residue with hot water, filter and make up to exactly 100 ml. (5) Det. the Cl^- content on 20 ml. by Mohr's method. This gives the total equivalents of Na + K. (6) Dil. an aliquot part of the soln. to 0.1 *N* Cl^- and add

0.5 ml. of 10% $(CH_3)_4NOH$ to 20 ml. dild. soln. Test this soln. polarographically under optimum conditions of capillary tube diam., temp. and sensitivity of the galvanometer. W. T. H.

Determination of ascorbic acid in different substances (according to the method of Devyatin and Iosikova). V. M. Iosikova. *Lab. Prakt.* (U. S. S. R.) **14**, No. 8, 13–18 (1939).—To det. ascorbic acid in plant substances, grind the chopped sample with 5–10 g. of a fine roasted sand or glass powder and with 10–20 cc. of 5% AcOH, wash the mortar with 10–40 cc. of the same acid, centrifuge the mass or filter rapidly through gauze, to 10 cc. of the ext. add 0.4 g. of dry finely ground $CaCO_3$, shake, add 5 cc. of 5% $Pb(CH_3COO)_2$, shake and centrifuge rapidly (or filter). Titrate 10 cc. of the filtrate plus 5 cc. of 80% AcOH with a 0.001 *N* soln. of 2,6-dichlorophenolindophenol until a clear pink color is obtained which persists for 1–2 min. The wt. of the sample to be used varies with the content of vitamin C, the consistency, vol. etc. The amt. of AcOH can also vary from 20 to 60 cc., but to insure accurate results the amt. must be carefully calcd. The whole process should not take more than 15–20 min. because the reducing properties of the exts. are lowered on prolonged standing. Colored exts. may be dild. with distd. water (from 1:1 to 1:20) before titration, or the filtrate may be treated with H_2S after the pptn. with $Pb(CH_3COO)_2$. The method for the calcn. of the ascorbic acid content and a no. of specific examples are given. Detn. of the oxidized form of ascorbic acid (overripe tomatoes) is described. W. R. Henn

A new modification of the method of Cajal for the impregnation of peripheral nerves with silver nitrate. A. G. Chernyakhovskiĭ. *J. méd., Ukraine* **9**, 93–8(in French, 98)(1939).—The tissue is treated successively for 24-hr periods with a soln. of 60 parts of EtOH and 10 parts each of Et_2O, C_5H_5N and $CHCl_3$, followed by EtOH, C_5H_5N, running H_2O, 20% chloral hydrate contg. 2–5% HNO_3, running H_2O and finally a soln. of 1 drop of concd. NH_4OH in 10 cc. of EtOH. It is then placed in 2% $AgNO_3$ at 37° for 10–15 days. Reduction is carried out in pyrogallol soln. with HCHO, after which the procedure is the same as for the Cajal method (*Trabeau d. Labor. d. r. b. de Madrid*, **23**(1925)). S. A. Karjala

The determination of aromatic substances in human bile. A. P. Shtraikher. *Klin. Med.* (U. S. S. R.) **16**, 526–8 (1938).—The concn. of aromatic substances in human bile parallels that in the urine and blood and can be used for diagnostic purposes in pathol. cases. S. A. Karjala

The photometric determination of tryptophan, tyrosine, diiodotyrosine and thyroxine. Erwin Brand and Beatrice Kassell. *J. Biol. Chem.* **131**, 489–502(1939).—The photometric detn. of tryptophan, tyrosine, diiodotyrosine and thyroxine described is based on the procedure developed by Lugg (*C. A.* **32**, 7948[7]) from the Folin and Ciocalteu method (*C. A.* **21**, 3210). Hydrolysis with alkali or with alk. stannite is followed by the sepn. of tyrosine and tryptophan as Hg compds. and their detn. by the Millon reaction with a Pulfrich photometer. Diiodotyrosine and thyroxine give no Millon reaction before or after hydrolysis with alkali but during hydrolysis with alk. stannite both are converted into reactive phenols, the former quantitatively to tyrosine and the latter probably to diiodothyronine or thyronine. Hydrolysis of a thyroid prepn. with alk. stannite therefore yields a higher tyrosine value than with alkali alone, the difference being a measure of the amt. of the iodoamino acids present. The tyrosine equivs. of the 2 iodoamino acids are so different that it is possible to ascertain the content of diiodotyrosine and thyroxine in thyroid prepns. from a consideration of the extra tyrosine together with the total (org.) I content. The results of analyses of normal thyroid prepns. by the new method indicate a thyroxine content somewhat higher than that found by the method of Leland and Foster (*C. A.* **26**, 2759) but lower than that found by the Harington and Randall method (*C. A.* **24**, 2237). The application of the new method to the evaluation of com. thyroid prepns. is feasible and recommended. Small quantities of material are required and the analysis is comparatively easy. Representative results are given for cryst. egg albumin, cattle fibrin and several thyroid prepns. A. P. Lothrop

Biochemical studies on carbohydrates. LII. Estimation of free amino sugar in normal and diabetic urines. Masato Ysbitake. *J. Biochem.* (Japan) **30**, 199–203 (1939); cf. *C. A.* **34**, 1066[9].—Adjust the urinary reaction to pH 6.8 with 30% AcOH. Add 4 cc. 37.9% (neutral) $Pb(AcO)_2$ to 20 cc. urine, centrifuge and delead with H_2S. Drive off excess H_2S by aeration and filter through an ultrafiltration membrane. (This membrane is made by impregnating a hardened paper with 4% collodion and drying in air for 5 min. After the treatment is repeated the membranes are preserved under distd. water.) Pass a current of ether through the filtrate for 90 min., drive off the ether, and autoclave 6 cc. with 4 cc. 2 *N* HCl at 150° for 10 min. Cool, neutralize the contents with Na_2CO_3 (anhyd.) to pH 6.8, transfer to a 25-cc. vol. flask and proceed with the detn. according to Masamune and Nogazumi (*C. A.* **32**, 1734[4]) with acetylacetone. S. Morgulis

Determination of galactose in blood. P. A. Larsson and S. L. Sveinsson. *Skand. Arch. Physiol.* **83**, 58–67 (1939).—Measure 0.3 cc. blood into a test tube contg. 2 cc. 0.1 *N* NaOH and 9.7 cc. 0.45% $ZnSO_4$, boil in a water bath 4 min., cool and centrifuge sharply. Pour about 10 cc. of the centrifugate into a tube contg. previously washed bakers' yeast and centrifuge after standing 15 min. at room temp. Measure 4 cc. of the clear fluid (= 0.1 cc. of the original blood), det. sugar by the Hagedorn-Jensen procedure (cf. *C. A.* **24**, 5324), and read the mg. % galactose off a calibration diagram or from the table of empirical values. To det. the fermentable sugar on the same sample run a sugar analysis both before and after the fermentation. S. Morgulis

Determination of crystalline androsterone with the Evelyn photoelectric colorimeter. Harry B. Friedgood and Helen L. Whidden. *Endocrinology* **25**, 919–24(1939); cf. *C. A.* **33**, 9401[6].—A modification of the Zimmermann procedure for color development (cf. *C. A.* **31**, 2626[4]) was applied to the assay of cryst. androsterone, and the Evelyn photoelec. colorimeter (cf. *C. A.* **31**, 1836[8]) was calibrated for the technique in terms of androsterone. The data indicate a high degree of reliability and reproducibility of results in the assay of cryst. androsterone. Felix Saunders

Modification of the Zondek alcohol method for determining both luteinizing and follicle-stimulating principles in the urine. Robert T. Frank. *Endocrinology* **25**, 996–7 (1939).—A modification of the Zondek alc. method (*Klin. Wochschr.* **9**, 964(1930)) is described for concg. both the follicle-stimulating and luteinizing factors. F. Saunders

Modern methods for the determination of sulfur and cystine in sheep wool and other proteins. Alfons Schöberl and Paul Rambacher. *Klepzig's Textil-Z.* **42**, 369–71 (1939).—A detailed discussion with 24 references. Leopold Scheflan

A simple electrode for rapid pH determination in living tissues, and certain data on functional shifts of pH in organs. A. O. Voynar. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 411–14(1937)(in English).—A pinch of quinhydrone is placed on the organ and the electrode thrust in. The connecting tube filled with agar-KCl only touches the surface. Organs of living animals always were found to be more alk. than the same organs immediately after death. When the pancreas secretes changes in pH are biphasic. At the beginning of secretion it was alk. and later acid. Slight changes were detected in the brain after physiol. excitation. Walter H. Secgers

Method for the microdetermination of histidine. Zenya Kurihara. *J. Biochem.* (Japan) **30**, 205–16(1939).—Measure 20 cc. urine into a cylinder and make slightly alk. to phenolphthalein (1 drop of 1%) with an alk. phosphate soln. (mixt. of equal parts 10% NaOH and 10% Na_2HPO_4). Dil. to 25 cc., shake with about 0.1 g. activated C and filter. Measure 20 cc. of the colorless filtrate into a centrifuge tube, add 1 g. NaCl and 2 cc. $HgCl_2$ reagent (dissolve 70 g. cryst. AcONa and 10 g. NaCl in

150 cc. satd. $HgCl_2$), make slightly alk. with satd. borax soln. and centrifuge off the ppt. Transfer the ppt. to a small graduated centrifuge tube and again centrifuge and fill up to the 4-cc. mark with 4% CCl_3COOH. Drop in a tiny particle of Na_2S, whereupon a ppt. is produced. Filter directly through a dry paper into a separatory funnel. Brominate 4 cc. filtrate with 1 cc. of a mixt. of 95 cc. $CHCl_3$ + 5 cc. Br_2 by shaking vigorously and drawing off the $CHCl_3$ layer after 10 min. Decolorize the aq. layer with 2 cc. 8% CCl_3COOH in $CHCl_3$, and filter through a dry paper. Carry out the color development on 1 cc. filtrate pipetted into a 10-cc. cylinder. Add 4 cc. of an acetate buffer of pH 4.6 (100 cc. 16% $AcONH_4$ + 57 cc. 30% AcOH) and dil. to 5 cc. with 0.6% KCN, mix and leave 25-30 min. Dil. to 7 cc. with glycerol (2 1), make up to 10 cc. with 20% KOH and mix. For the standard, treat 2 cc. *M*/80 histidine monochloride (1 cc. = 1.84 mg. histidine) with 2 cc. CCl_3COOH, brominate and proceed as with the unknown sample, and compare the colors.
S. Morgulis

Analysis of [biol. tissues or fluids] for traces of metallic impurities (Owens, Reinhardt) 7.

C—MICROBIOLOGY

LAWRENCE H. JAMES

The influence of vitamin C (*l*-ascorbic acid) on the whooping cough bacillus and its toxin. Tosio Otani. *Oriental J. Diseases Infants* **25**, 1-2(1939)(in English).—Vitamin C *in vitro* had a greater effect on the whooping cough bacillus than on any of the other bacilli tested, repressing its growth, inducing a degenerative metamorphosis and reducing its toxicity. The whooping cough bacillus which has undergone this degenerative metamorphosis produces in the test animal a neutral polynuclear leucocytosis rather than the lymphocytosis produced by the original whooping cough bacillus; it has about the same degree of reaction (agglutination and complement-binding reaction) and capacity of forming antitoxin as the original bacillus. The toxin of the whooping cough bacillus is neutralized and detoxified *in vitro* by vitamin C. Ruth Berggren

The growth-promoting substance of brewers' yeast as a growth-inhibiting factor for yeast, and its effect upon the economic coefficients. Vagn Hartelius. *Compt. rend. trav. lab. Carlsberg, Sér. physiol.* **22**, 387-404(1939).—See *C. A.* **33**, 7343[6]. H. Game

Electrophoresis of glucide-lipide antigens O and Vi extracted from typhoid bacilli. Cornelia Combiesco and Eugenia Soru. *Compt. rend. soc. biol.* **132**, 172-4(1939).—Alone, the virulence antigen Vi, at pH 2-9, has an elec. charge 4-5 times greater than that of the somatic antigen O. But when both antigens are present in the same soln. they are transported with approx. equal velocities.
L. E. Gilson

Forssman antigens in human erythrocytes type A_1. H. Brocks. *Compt. rend. soc. biol.* **132**, 230-3(1939).
L. E. Gilson

Production of pyrogen in serums by bacteria. F. W. Co Tui and M. H. Schrift. *Proc. Soc. Exptl. Biol. Med.* **42**, 549-52(1939).—Preliminary. L. E. Gilson

Ultraviolet absorption spectra of active and inactive yeast. Ernest W. Landen and Fred M. Uber. *Proc. Soc. Exptl. Biol. Med.* **42**, 559-63(1939).—The ultraviolet absorption spectrum of *Saccharomyces ellipsoideus* shows a max. at 265 mμ. The extinction coeff. for the max. decreases for inactive cells revealing a secondary max. at 280 mμ. Agreement with the theory of Caspersson (*C. A.* **30**, 8267[6]) on nucleic acid metabolism as a division function of division rate is obtained. Methods are described.
L. E. Gilson

Action of sulfanilamide on hemolytic enterococcus (Streptococcus fecalis hemolyticus). Erwin Neter. *Proc. Soc. Exptl. Biol. Med.* **42**, 668-72(1939).—The bacteriostatic action was slight and varied with the compn. of the culture medium. L. E. Gilson

Dry culture media. R. V. Litvak. *Lab. Prakt.* (U. S. R.) **14**, No. 8, 2-4(1939).—Directions are given for the prepn. of agar-agar and of bouillon No. 2 TsIEM prepd. from fish-waste products as well as the dry medium prepd. from meat waste products. The dry media are as suitable as the ordinary culture media, and in some of their properties are superior. W. R. Henn

The nutrition of Corynebacterium diphtheriae. Pantothenic acid as an essential growth factor for certain strains of C. diphtheriae gravis: the synthesis of some physiologically active compounds by C. diphtheriae cultures in synthetic media. W. C. Evans, W. R. C. Handley and F. C. Happold. *Brit. J. Exptl. Path.* **20**, 396-408(1939); cf. *C. A.* **33**, 5443[8].—The factor present in tissue exts., required by certain exacting strains of *C. diphtheriae gravis* for growth in synthetic medium, has similar properties to and can be replaced by pantothenic acid. *Mitis* and some *gravis* strains grown in a synthetic medium consisting of amino acids, lactate and salts, together with the 3 growth factors of Mueller—nicotinic acid, pimelic acid and β-alanine—can synthesize pantothenic acid. Sterile filtrates of these strains grown in this medium support the growth of exacting *gravis* strains. *C. diphtheriae* strains (both *mitis* and *gravis*) grown in synthetic medium also synthesize substances with physiol. activities similar to aneurin, coenzyme I or II and riboflavin. Harriet F. Holmes

The bios requirements of various strains of Saccharomyces cerevisiae. C. Rainbow. *J. Inst. Brewing* **45**, 533-45(1939).—The present chaotic state of the bios literature is due to variations in (1) requirements of the particular strain used, (2) the compn. of the synthetic medium, (3) subculture methods, which may induce acclimatization, (4) seeding rates, growth period, temp., agitation and growth criteria. With "full wort growth" as the ultimate standard for complete stimulation 7 strains were classified into 3 groups: class A, no effect with inositol (I) or bios II B (III) and only slight effect with bios II A (II); class B, no effect with II and slight effect with I or III; class C, no effect with any single component, but large stimulation with I plus II. All classes gave excellent growth with all 3 components. β-Alanine replaces II with only 3 of the strains; vitamin B_1 stimulates only one. Twenty-two references. Quick Landis

The concentration and examination of the bios required by English brewery top fermentation yeast. C. Rainbow and L. R. Bishop. *J. Inst. Brewing* **45**, 593-605(1939); cf. preceding abstr.—With the Institute of Brewing yeast (class A) as a control test object II and III were fractionated from egg yolk to a concn. of 10^6 times the original. A rapid and a lengthy procedure is diagrammed. Since the final concentrates gave full wort growth at a concn. of about 10^{-7} g./cc. of synthetic medium they were deemed nearly pure and a combustion gave $C_7H_{11}NO_4$ for II and $C_7H_{12}N_2O_3$ for III. The mol. wts. (cryoscopic) were 173 and 180, resp. Other tests indicate that II is probably β-alanine linked with an unidentified hydroxy acid. Five components of "bios" exclusive of "Z factors" are recognized; I, II, III, vitamins B_1 and B_6, not all of which are required by all yeasts. Twenty-four references. Q. L.

Bacteriological dissimilation of carbohydrates. C. H. Werkman. *Bacteriol. Revs.* **3**, 187-225(1939).—A detailed review with 127 references. John T. Myers

The endogenous respiration of Bacillus cereus. I. Changes in the rate of respiration with the passage of time. M. Ingram. *J. Bact.* **38**, 599-612(1939).—When cells of *B. cereus*, grown on nutrient agar at 25° for less than 24 hrs., are washed and suspended in distd. water or buffer soln. cell division continues and gives rise to an unusually high rate of respiration. If the cells are 24 or more hrs. old, no cell division occurs and the endogenous respiration passes through 3 phases. The first phase usually lasts less than 2 hrs. Its duration is greater with older cells, but is not much affected by temp. The large uptake of O is attributed to the satisfaction of an O debt arising from asphyxia during washing. The second phase lasts about 5 hrs. at 25°, and during this time the rate of respiration remains const. During the third phase the rate of respiration declines exponentially with time, but this is not due to decrease in food supply. During endogenous respira-

tion, the cells diminish in size and lose their fatty materials and their Gram-pos. reaction. The low R.Q. (0.7) indicates that the fat is probably destroyed by respiration which leads to the loss of the outer Gram-pos. sheath of the cells. The addn. of NaCl does not destroy the 3 phases. 20 references. **II. The effect of salts on the rate of absorption of oxygen.** *Ibid.* 613-29.—The important factor in the detn. of rate of respiration is the concn. of salt present. All salts increase the rate of respiration when present in low concn. and decrease it at higher concns., unless special specific toxic properties of certain ions intervene. This is not due to osmotic changes. The increased respiration by unbuffered dil. saline suspensions is brought about by the cation of the salt; the salts of uni-, bi- and trivalent cations are equally effective at concns. roughly in the ratio of 1000; 100; 1. When buffered at pH 6 this stimulating action is slightly increased, probably because of the greater acidity. The inhibitory effect of high salt concns. is probably due to the cations. There is no antagonistic effect between the ions of Na and K, and a slight interaction between Na and Ca in dil. solns. only. 20 references. John T. Myers

Nutrient requirements of butyric acid-butyl alcohol bacteria. R. W. Brown, H. G. Wood and C. H. Werkman. *J. Bact.* **38**, 631-40(1939).—An ether-sol. ext. of "Difco" yeast ext. and of Speakman's salts are essential growth factors in media contg. $(NH_4)_2SO_4$ as a source of N. Neither the Speakman salts minus the phosphates nor phosphates without the other inorg. salts are sufficient for growth in successive transfers. The ether-sol. yeast ext. is not altered by prolonged heating in N H_2SO_4. Numerous substances known to be growth factors for organisms did not replace yeast ext. for growth of butyric acid-butyl alc. anaerobes (thiamine, riboflavin, tryptophan, cystine, asparagine, nicotinic, pimelic and pantothenic acids, alanine and uracil. These substances do not stimulate utilization of glucose when added to media contg. an amino acid mixt. In the presence of purified hydrolyzed casein as a source of N and glucose as a source of C, phosphates alone were essential for growth, other inorg. salts being included in the casein. An ether-sol. stimulant could not be demonstrated in the hydrolyzed casein, its stimulating effect being due to the amino acids. Glucose is dissimilated with the formation of normal products in media contg. $(NH_4)_2SO_4$ or casein hydrolyzate as a source of N when the other essential nutrients were present. 15 references. John T. Myers

The nature of the catalase reaction in the residue of Staphylococcus aureus lysed by bacteriophage. F. Lyle Wynd and J. Bronfenbrenner. *J. Bact.* **38**, 659-75 (1939).—Cultures of *Staphylococcus aureus* lysed by bacteriophage exhibit no utilization of O. Lysis does not alter the catalase activity of the organism. The catalase present in the filtrate of lysed cells is in a very labile condition and it appears to destroy H_2O_2 by an irreversible stoichiometrical reaction. This catalase reaction is inhibited by cyanide. The destruction of H_2O_2 follows the equation for the unimol. reaction and the reaction const. is that of the rate of inactivation of the enzyme and not that of disappearance of the substrate. When catalase is more or less freed from intimate assocn. with cellular structures it is unable to enter reversibly into the catalyzed reaction. 16 references. John T. Myers

The use of the quinhydrone electrode for correlating final hydrogen-ion concentration and pigmentation of actinomycetes growing on agar. Jean E. Conn. *J. Bact.* **38**, 679(1939).—The pigments of these cultures act as indicators changing, resp., from blue to red, violet to red bright red to pink and black to light brown as the acidity of the medium increases. John T. Myers

Alcohol- and acid-resistant bacteria. J. Guilherme Lacorte. *O Hospital* **16**, 511-22(1939).—A review on germs resistant to the action of dil. acids and alc., especially *Mycobacterium tuberculosis* and *M. leprae*. G. N.

A simplified apparatus for the preservation of bacterial cultures in the dried state. Merlin L. Cooper and Frank J. Grabill. *J. Lab. Clin. Med.* **25**, 184-8(1939).—A simple inexpensive low-vacuum app. is described that employs the method developed by Flosdorf and Mudd (*C. A.* **30**, 4189[1]; *J. Immunol.* **34**, 469(1938)). H. W. R.

A physicochemical study of neurotropic viruses and their relation to the components of the nervous tissue. L. S. Ratner. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 426-8(1937) (in English).—Virulent brain tissue can be dried without destroying equine encephalomyelitis. Lipoid solvents do not ext. the virus. Likewise, proteins obtained by extg. dry or wet brains with 10% NH_4Cl or $(NH_4)_2SO_4$ were found inactive. Walter H. Seegers

Biotin as a growth factor for the butyl alcohol-producing anaerobes. Esmond E. Snell and Roger J. Williams. *J. Am. Chem. Soc.* **61**, 3594(1939).—Biotin proved to be approx. 500 times as active as "liver concentrate" (McDaniel, Woolley and Peterson, *C. A.* **33**, 4285[8]) and is evidently the only substance required in addn. to the ordinary nutrients for the BuOH-producing clostridia. Hydrolyzed casein evidently contains small amts. of some substance which is in this case physiologically equiv. to biotin. C. J. West

D—BOTANY

THOMAS G. PHILLIPS

Legume nodule metabolism and nitrogen fixation. Franklin E. Allison, C. A. Ludwig, Sam R. Hoover and Francis W. Minor. *Nature* **144**, 711-12(1939); cf. *C. A.* **29**, 5145[5]; **33**, 3055[2].—Variations in behavior between samples of nodules of 12 different species of legumes were not much greater than between samples of the same species; this was also true for their root tissues. The relative rates of respiration and R.Qs. of nodules and roots in different partial pressures of O showed that the inner tissues of most nodules in air and of large nodules in O were partially anaerobic. Small roots apparently contained less available carbohydrates than nodules. Under anaerobic or partially anaerobic conditions both nodule and root tissues formed C_2H_5OH; under aerobic conditions the C_2H_5OH was completely oxidized to CO_2 and H_2O. A considerable portion of the N in the nodules is either in storage, translocatory or other biologically inactive compds. Attempts to obtain N fixation by detached nodules were, in general, unsuccessful. Most of the carbohydrate supply which dets. largely the magnitude of N fixation is used by the host in its growth processes. Ruth Berggren

Color phenomena of chlorophyll. H. Lauth. *Deut. Apoth.-Ztg.* **54**, 1078-9, 1100-1(1939).—23 references. W. O. Emery

Quantum efficiency of photosynthesis in Chlorella. II. H. G. Petering, B. M. Duggar and Farrington Daniels. *J. Am. Chem. Soc.* **61**, 3525-9(1939).—The quantum yields in photosynthesis by algae have been measured under a variety of conditions; the dropping mercury electrode was used for the rapid measurement of dissolved O. The results show that at 25°, 0.04 to 0.1 mol. of O is evolved in photosynthesis by *Chlorella* per quantum of red light absorbed. These data agree with those reported earlier (cf. *C. A.* **32**, 2982[9]), but are in definite disagreement with those of Warburg and Negelein (cf. *C. A.* **18**, 1316) who reported an efficiency of 0.25. The discrepancy between the results can be explained in part by the different methods of measurements. A. B. Garrett

The chemical composition of wood bark. V. I. Sharkov, Z. A. Tyagunova and V. N. Kolpina. *Lesokhim. Prom.* **6**, No. 2, 9-10(1938); *Khim. Referat. Zhur.* **2**, No. 3, 123 (1939); cf. *C. A.* **33**, 5651[1].—By extn. of the bast of pine with boiling water and with 96% alc. followed by an extn. of the residue with $(NH_4)_2C_2O_4$ soln. it was possible to sep. pectin hydrate, from which the pectin insol. in 70% alc. was sepd. An analysis of the pectin gave 57.5% of polyuronides, 12.6% of pentosans, 2.0% of methoxides, 4.2% of lignin, 1.6% of ash and about 3% of volatile acids. The nature of the remaining 20% of substances is not yet detd. The polyuronic acids contain galacturonic acid. In the pectin obtained from the bast of birch were found up to 71% of uronic acids. In its methoxide content (3.4%) it resembles the pectin obtained from the bast of pine.

The pectins of bark possess no jellying properties, probably owing to the low content of the methoxides. W. R. Henn

The constancy of chemical properties of the tung tree. E. N. Taran. *Sovet. Subtropiki* **1938**, No. 3, 61-3; *Khim. Referat. Zhur.* 2, No. 3, 60(1939).—Seeds of a tung tree contained oil 63.29, ash 2.57 and crude protein 17.87%. Seeds of a graft of this tree contained, resp., 64.07, 2.73 and 16.46%. The physicochem. consts. of oils obtained from the original trees and from the grafts varied only in limits of exptl. errors. The activities of the catalases of the original tree and of the graft were practically the same. W. R. Henn

The absorption of nutritive substances by plants. F. Gessner. *Z. ges. Naturw.* 5, 187-96(1939).—The addn. of Hoagland soln. (LiCl 0.5 g., $CuSO_4$ 1.0 g., $ZnSO_4$ 1.0 g., TiO_2 1.0 g., H_3BO_3 11.0 g., $Al_2(SO_4)_3$ 1.0 g., $SnCl_2$ 0.5 g., KI 0.5 g., $MnCl_2$ 7.0 g., $NiSO_4$ 1.0 g., $Co(NO_3)_2$ 1.0 g. and KBr 0.5 g.) increased the wt. of peas 69%, of sugar cane 200-300%, of tobacco 100-180% and of scarlet beans 64%. The absorption of nutritive substances by plants is regulated not by the roots alone, but by the plant as a whole. The transformation of the substances in the plant is an important factor in the absorption of nutritive substances. The optimum temp. is 15-30°. W. R. H.

The injection of growth substance into plants. K. Weissenbock and A. Stern. *Botan. Arch.* 39, 315-31 (1939).—Sprouts of *Sedum praealtum* when injected with a satd. heteroauxin soln. were caused to curve about 45° in 1 hr. Many curvatures ultimately reached an angle of 180°. The plants bend away from the injected side. The reaction was especially strong with 14-day-old seedlings of *Phaseolus multiflorus*, which after 2-3 hrs. had reached the extent of curvature requiring 2-3 days when the growth substance was applied in the form of paste. The floral stems of *Galanthus* and *Hyacinthus* were accelerated in growth, increased in length and had the death of stock delayed by the injection of heteroauxin. The injection method of applying the growth substance appears to have considerable advantage over other methods of application; the concn. is better controlled and the material is more certainly introduced into plants which are difficult to affect by external application. 28 references. C. K. Horner

The uptake of carbonic acid by the roots of green plants. Ortrud Overkott. *Botan. Arch.* 39, 389-443(1939); cf. *C. A.* 33, 687³.—The assimilation of CO_2 by the roots of various plants was demonstrated from solns. of $KHCO_3$ in distd. H_2O (pH around 8.3), from H_2O contg. CO_2 (pH 4.5-7) and from modified Knop's nutrient soln. contg. various concns. of $KHCO_3$. If the concn. of $KHCO_3$ or CO_2 was around 30 mg. CO_2 per 100 cc., the uptake was about equal to the CO_2 liberated in the respiration of the roots. This equil. point varied with the exptl. series and type of plant. Analyses of several soils showed that the concn. of CO_2 in the soil soln. varies between 40 and 80 mg. in 100 cc. Calcns. indicate that the CO_2 absorbed by the roots in the transpiration stream under natural conditions could amount to 5-20% of the av. assimilation by the leaves and may even be as much as 50%. Direct expts. with the aerial portion of plants in a CO_2-free atm. and the roots in substrates contg. CO_2 showed that the assimilation of CO_2 by the roots alone was not sufficient for the total C economy of the plant. 57 references. C. K. Horner

Chromosome doubling in potatoes induced by colchicine treatment. Francis E. Johnstone, Jr. *Am. Potato J.* 16, 288-304(1939).—By treating the seed with 0.25-1.0% aq. solns. of colchicine, chromosome doubling was induced in a no. of cultivated and wild species of *Solanum*. The most satisfactory method was to germinate the seed in an approx. 0.5% soln. of colchicine at a temp. that insured rapid and even germination. Observations on colchicine-treated plants that gave rise to polyploids indicated that it it necessary to approach the lethal dosage in order to get doubling of an entire growing point. K. D. Jacob

Effect of temperature on the reversible activity of invertase in forage grasses as dependent on their cold and heat resistance. A. S. Morozov. *Compt. rend. acad. sci. U. R. S. S.* 23, 949-51(1939)(in English).—Expts. with hibernating leaves of *Bromus inermis* and *Lolium perenne* taken from under the snow and (with the second plant) also grown in a greenhouse, with reference to the synthesizing and hydrolyzing activity of invertase at temps. ranging from −5 to +50° yielded results pointing to important deviations of the enzymic activity in meadow grasses connected with the effect of high and low temps. Enzymes and biochem. processes in plant tissues play a most important part in the drying of plants subjected to high and low temps. A. H. Krappe

The influence of aneurin and biotin on the growth of some mycorrhizal fungi. Preliminary note. E. Melin and G. Lindeberg. *Bot Notiser* **1939**, 241-5; *Rev. Applied Mycol.* 18, 542.—By means of Fries's technique (cf. *C. A.* 33, 9359²) the influence of aneurin, yeast filtrate, biotin and inositol on the development of 7 mycorrhizal fungi was tested. Biotin and inositol alone or jointly failed to improve the growth of any fungi but in combination with aneurin both exerted a beneficial effect. Aneurin and yeast filtrate showed substantial beneficial effects on growth of fungi over the controls, the yeast filtrate causing generally the greater increase in growth. Oden E. Sheppard

Spruce mycorrhiza in the light of modern growth-substance research. B. Lindquist. *Bot. Notiser* **1939**, 314-55; *Rev. Applied Mycol.* 18, 608-9.—The effects of exts. from pure cultures of mycorrhiza-forming and other soil fungi on spruce seedlings grown in Erlenmeyer flasks on sand with the addn. of a synthetic soln. were studied. Only the secretions of the unnamed hyaline mycelium 82c, that of mycelium *Radicis nigrotrigosum* and that of mycelium 19f showed a stimulus to development of the spruce seedlings. Secretions from some had no effect at all while that from others caused retardation in growth. The paper critically discusses the theories to explain these effects including the N and mineral salt theory of Frank and the growth-substance interaction theory. O. E. S.

The influence of twelve elements on the growth of the potato. D. A. van Schreven. *Mededeel. Inst. Phytopath. Wageningen* 84, 1-166(1939); *Rev. Applied Mycol.* 18, 515; cf. *C. A.* 33, 9525⁵.—The effects of Fe, Zn, Na and Cl in various concns. on the growth of several potato varieties are shown. Plants suffering from P, Zn or B deficiency simulate primary leaf-roll symptoms. True leaf roll, however, can be differentiated from nutritional disorders by phloem necrosis, in which the dead sieve tubes react to phloroglucin and HCl by a red coloration absent from the disorganized tissues of plants affected, for instance by lack of B. In several cases of B deficiency, moreover, the damage is not restricted to the phloem, as it invariably is with leaf roll. Medullary necrosis, due to Ca deficiency, is stated to occur sporadically in Holland. O. E. S.

Plant viruses. I. Serological, chemical and physicochemical properties. F. C. Bawden and N. W. Pirie. *Tijdschr. biol. den Haag* 16, 355-71(1938); *Rev. Applied Mycol.* 18, 540.—Tables are presented showing the properties of plant viruses in crude infective sap, their serological reactions, activity of purified virus prepns., approx. weight of virus in 1 l. sap, analytical compn., pptn. and isoelec. points, inactivation by acid and alkali (pH stability ranges), effect of enzymes, shape of virus particles, sedimentation consts., viscosity, specific vol. and specific gravity, and ultraviolet absorption spectra of solns. of purified plant viruses. Oden E. Sheppard

Experiments with plant-growth substances for the rooting of cuttings. C. R. Metcalfe and W. G. Templeman. *Bull. Misc. Inform., Kew* No. 8(1939).—Expts. with 3 growth substances, β-indolylacetic acid, β-indolylbutyric acid and α-naphthaleneacetic acid, on the rooting of cuttings of a large no. of trees, shrubs and herbaceous plants are described. Acceleration of root production was obtained in about 50% of the large no. of expts., with one or another of the growth substances used. L. G. G. Warne

Wound hormones of plants. IV. Structure and synthesis of a traumatin. James English, Jr., James Bonner and A. J. Haagen-Smit. *J. Am. Chem. Soc.* 61, 3434-6 (1939); cf. *C. A.* 33, 7347⁹.—The cryst. substance iso-

lated from string bean pods and capable of inducing renewed cell division and cell extension activity in the parenchymatous cells of the bean pod mesocarp is shown to be 1-decene-1,10-dicarboxylic acid (I), m. 165–6°, since catalytic reduction gives decan-1,10-dicarboxylic acid (II), m. 171° and oxidation of the Me ether with $KMnO_4$ gives sebacic acid. Me undecylenate with O_3 gives 40% of the half aldehyde of Me sebacate; refluxing with $CH_2(CO_2H)_2$ and C_5H_5N for 4 hrs. (evolution of CO_2) and hydrolysis with dil. HCl give I; *S-benzyl thiuronium salt.* I is termed *traumatic acid.* I is capable of inducing wound periderm formation in washed disks of potato tuber and to function thus as a wound hormone of the potato; it is also capable of partially replacing the juice of the tomato fruit in reversibly inhibiting the germination of tomato seeds. II has an activity about half that of I; the satd. dibasic acids possessing 7 or fewer C atoms were without significant activity. Suberic and azelaic acids possess slight activity and sebacic acid is approx. half as active as I; succinic acid is completely inactive but maleic acid evokes a small but definite response in the bean test. Two CO_2H groups appear to be essential for wound hormone activity. C. J. West

Method for detg. glutamine in plant tissues (Pucher, Vickery) 7. Photocalorimeter—quantum efficiency of photosynthesis in algae (Magee, *et al.*) 3. Action of local anesthetics on plant cell (Régnier, Quevauviller) 17.

E—NUTRITION

PHILIP B. HAWK

The value of the sweet potato in human nutrition. Wm. H. Adolph and Hsi-Chen Liu. *Chinese Med. J.* 55, 337–42(1939).—Three adults were fed sweet potato only for periods of 5 to 8 weeks. N balance was maintained with a daily intake of 2 kg. of sweet potato per day. W. H. A.

Chinese dietary standards and some dietary problems among refugees. Hsiang-Chuan Hou. *Natl. Med. J. China* 25, 129–43(1939). Wm. H. Adolph

Studies on röntgenographic changes in bones as an early sign of scurvy in infants. P. W. Braestrup and Sv. A. Chrom. *Acta Paediat.* 27, 63 6(1939)(in English).—The ascorbic acid content of the plasma, detd. by the method of Farmer and Abt (*C. A.* 30, 8273[8]), varied from 0.00 to 0.28 mg. % in 25 sick infants, 2–23 months of age. The av. normal values of bottle-fed and breast-fed infants in Copenhagen were approx. 0.24 and 1 mg. % (lower limit 0.5 mg. %), resp. None of the sick infants showed the röntgenographic changes described by Park, *et al.* (*Arch. Disease Childhood* 10, 265-94(1935)). Ruth Berggren

Vitamin C and opsonic power of the blood. Cesare Ardy. *Pathologica* 31, 384–8(1939).—Vitamin C injected in guinea pigs increases the opsonic power of the blood, which in scorbutic animals is almost zero. A modification of the detn. of the opsonic power by the method of Wright (cf. Brocq-Rousseau and Roussel, *Sérum normal—Propriétés physiologiques, C. A.* 33, 4306[2], p. 174) is proposed. G. A. Bravo

The nutritional availability of iron in molasses. Robt S. Harris, L. Malcolm Mosher and John W. M. Bunker. *Am. J. Digestive Diseases Nutrition* 6, 459–62(1939).—The availability of the Fe of 3 grades of molasses (1st, 2nd and 3rd) was detd. by chem. (Hill's dipyridyl method) and biol. (hemoglobin studies on anemic rats on a low-Fe diet) procedures. From chem. studies the availability of Fe was found to be, resp., 97, 85 and 54%. From biol. studies the availability was, resp., 90, 80 and 50%. Molasses is a rich and inexpensive source of Fe. E. E.

The effects of vitamin deficiency on the gastrointestinal tract. Dwight L. Wilbur. *Am. J. Digestive Diseases Nutrition* 6, 610–17(1939).—A review with 64 references. Edward Eagle

Bone diseases caused by disturbances in the mineral metabolism. József Marek. *Math. naturw. Anz. ung. Akad. Wiss.* 58, 429–45(1939).—The etiology, pathogenesis and biochemistry of rickets, osteomalacia, fibrous osteodystrophia and osteoporosis are discussed. In rickets, mineral abnormalities of the diet can be detd. by investigating the Ca and P contents of the blood serum. On an alkaligenic diet, a Ca content below the lowest normal values prevents the hormonal action of the parathyroid. The inorg. P content increases with both an acidogenic P-rich diet and a low Ca intake. Vitamin D has very little effect when the Ca and P ratio is normal, but has a regulating effect when the diet is abnormal. Hormones seem to play some role, but a purely hormonal rickets is not confirmed yet. The deposition of Ca salts in the bone substance is connected with the presence of a phosphatase formed by the organism and with a basophil chemical compn. of blood serum. Abnormal chemical compn. of the serum may cause the Ca to be dissolved out of the bone deposits. The etiology of osteomalacia is very similar to that of rickets. Osteodystrophia fibrosa seems to occur on one-sided P-rich diets contg. $CaO:P_2O_5$ in a ratio of less than 1:2. The epidemic osteofibrosis of horses diminishes the Ca level of serum below the lowest normal values and increases the inorg. P content. Human osteodystrophia fibrosa generalis is connected with an increased activity of parathyroids. The Ca level of blood serum increases from 9–11 to 17–23 mg. % and the inorg P content is below the normal. S. S. de Finály

Curing of rickets by a single dose of vitamin D. Pál Mödlinger. *Orvosi Hetilap* 83, 970–1(1939).—Clinical expts. proved that a single large dose of vitamin D injections contg. in 1 cc. 15 mg. vitamin D cured rachitic symptoms and prevented the appearance of rickets for 2.5 months on the average. S. S. de Finály

Effect of vitamin B_1 on morphine-abstinence symptoms. O. Garth Fitzhugh. *J. Pharmacol.* 67, 423–8(1939).—The irritability of albino rats addicted to ascending doses of morphine is significantly decreased by heavy doses of vitamin B_1. The vitamin also prevents the usual increase in irritability that follows morphine withdrawal. The effect is not due to any toxic action of the large doses of B_1 used. L. E. Gilson

Effect of dihydrotachysterol on various types of experimental rickets in rats. Alfred T. Shohl, Ch'uan H. Fan and Sidney Farber. *Proc. Soc. Exptl. Biol. Med.* 42, 529–34(1939).—Rickets caused by high-Ca low-P diets was not prevented by nontoxic doses of dihydrotachysterol (Holtz A. T. 10) which protected rats fed low-Ca high-P diets. L. E. Gilson

Further studies on relation of fat to utilization of lactose in milk. E. J. Schantz and C. F. Krewson. *Proc. Soc. Exptl. Biol. Med.* 42, 577–9(1939); cf. *C. A.* 32, 2576[2].—Natural fats and oils and even numbered chain fat acids contg. 12 or more C atoms when fed with skim milk to the extent of 3–4% were effective in preventing the loss of galactose in the urine while caproic, caprylic and capric acids and their glycerides were ineffective. The odd-chain fat acid, pentadecylic, was ineffective. Feeding glucose at levels of 8–10% in skim milk did not prevent loss of galactose. The excretion of galactose was increased as much as 20% by feeding 2% of NaCl or Na_2HPO_4 in the skim milk. KCl was not as effective in increasing galactose excretion. The above salts caused some excretion of galactose on whole-milk diets. L. E. Gilson

Occurrence of the pellagra-like syndrome in range chicks. Herman C. Mason. *Proc. Soc. Exptl. Biol. Med.* 42, 609–11(1939); cf. *C. A.* 33, 8712[4].—Lack of an unknown dietary factor seems to be responsible. L. E. Gilson

Natural vitamin K and synthetic vitamin K_1. S. Ansbacher, Erhard Fernholz and H. B. MacPhillamy. *Proc. Soc. Exptl. Biol. Med.* 42, 655–8(1939); cf. *C. A.* 33, 6922[9].—In blood-clotting expts. with chicks synthetic 2-methyl-3-phytyl-1,4-naphthoquinone (vitamin K_1), its "isophytyl" isomer, and 2-methyl-3-dihydrophytyl-1,4-naphthoquinone were considerably less potent than 2-methyl-1,4-naphthoquinone, 2-methyl-1,4-naphthohydroquinone diacetate and certain alfalfa concentrates. L. E. Gilson

Nitrogen retention on casein digests. Warren M. Cox, Jr., and Arthur J. Mueller. *Proc. Soc. Exptl. Biol. Med.* 42, 658–63(1939).—Whole casein and casein hydrolyzed

by trypsin gave a pos. N balance in rats. Acid-hydrolyzed casein gave a slightly neg. balance, but after addn. of 0.2% tryptophan a pos. balance. L. E. Gilson

Quantitative biological assay of vitamin K and its application to several quinone compounds. Flemintine P. Dann. *Proc. Soc. Exptl. Biol. Med.* **42**, 663–8(1939).—A 3-day curative technique using chicks is described. The vitamin K activity of a compd. varies significantly with the solvent and the method of administration. The vitamin K activity of 2-methyl-1,4-naphthoquinone and of 2-methyl-1,4-naphthoquinhydrone is approx. the same as that of natural vitamin K_1, on a molar basis. L. E. Gilson

Control of prothrombin deficiency in obstructive jaundice by use of vitamin K. John D. Stewart and G. M. Rourke. *J. Am. Med. Assoc.* **113**, 2223–6(1939).—Administration of a vitamin K-cholic acid mixt. contg. 0.45 g. Na glycocholate, 0.45 g. of Na taurocholate and 0.1 g. of ext. from 200 g. of fresh spinach tended to keep the prothrombin level in the blood above the danger level of 40%. F. P. Griffiths

Studies in lead mobilization. S. L. Tompsett and J. N. W. Chalmers. *Brit. J. Exptl. Path.* **20**, 408–17(1939).—In human cases of Pb poisoning and increased Pb absorption a study has been made of the effect of high-Ca diet and of low-Ca diet with and without NH_4Cl, which is an active mobilizer of Pb. High-Ca diets produced a fall in blood Pb, while low-Ca diets with and without NH_4Cl produced a rise in blood Pb. There was no parallelism between blood Pb level and Pb excretion in the 2 cases exaind. In mice fed with abnormal amts. of Pb, on a low-Ca diet Pb predominates in the soft tissues, although considerable amts. were found in the skeleton. On high-Ca diet Pb predominated in the skeleton but the amts. of Pb in the soft tissues was not negligible and was probably capable of producing change. Harriet F. Holmes

Oxidation-reduction and tissue changes during an insufficient-protein regime. M. M. Mir-Salimov. *J. méd. Ukraine* **9**, 39–48(in French, 47–8)(1939).—Rabbits on an insufficient-protein diet develop hypochromic anemia and leucocytosis, and lose wt. more rapidly than those on a protein-free diet. The total and reduced glutathione (I) of the blood and liver decreases, of skeletal and heart muscles increases, and of the spleen, kidney and adrenals remains within normal limits. The amt. of oxidized I in all the organs and blood increases while the glycogen reserve and anaerobic glucolysis in the liver and muscles decrease sharply. Liver respiration decreases, while muscle and kidney respiration increases. S. A. Karjala

The diagnosis of C hypovitaminosis by the method of saturation (new modification). I. I. Matusis. *Klin. Med.* (U. S. S. R.) **16**, 50–4(1938).—The daily elimination of vitamin C (I) in the urine of normal persons is 5–7 mg. %. The elimination of I in the urine reaches a max. of 14–15 mg. % 4–7 hrs. after ingestion of 300 mg. of I and falls to its original level in 24 hrs. When this max. is used as the criterion it is not necessary to take samples of urine through the entire 24-hr. period. Hypovitaminosis is diagnosed by ingestion of I and analysis of the eliminated I in the urine in 4–7 hrs. If this analysis shows less than 14–15 mg. % of I the patient is "unsaturated" with respect to I. S. A. Karjala

The elimination of quinine in urine under the influence of acidic or basic dietary regimes. L. Gnilosyrova-Gur'eva. *Klin. Med.* (U. S. S. R.) **16**, 386–7(1938).—An alk. dietary regime results in a retardation in the beginning and completion of quinine elimination in the urine and is recommended for malaria patients. S. A. Karjala

Carbohydrate metabolism under normal and pathological conditions. I. M. I. Barbas and L. S. Shvarts. *Klin. Med.* (U. S. S. R.) **16**, 509–13(1938).—The administration of 100 g. of sucrose to human subjects causes a sharp rise in blood sugar (I) in 30 min. followed by a decrease to normal in 60 min. in both venous and arterial blood. Glycogen (II) shows no increase in 30 min. in arterial blood but shows a sharp increase in 60 min., while venous blood shows an increase in 30 min. with a slight decrease from the max. in 60 min. The mg. % of II in arterial and venous blood before sucrose administration, after 30 min. and after 60 min., are 35 and 27, 37 and 48, and 67 and 40, resp. The injection of 20 units of insulin (III) results in a greater decrease in II in venous than in arterial blood. The mg. % of I in arterial and venous blood before, 30 min. and 60 min. after sucrose administration are 84 and 98, 134 and 124, and 103 and 90, resp. The same values after injection of III are 96 and 103, 101 and 99, and 79 and 77 mg. %, resp. II. L. S. Shvarts and M. I. Barbas. *Ibid.* 665–70.—In some cases of diabetes the arterial-minus-venous blood-sugar difference (I) is neg. but increases to a high pos. value 30–60 min. after sucrose administration, while the arterial-minus-venous blood glycogen difference (II) goes from 0 to a high pos. value in 30 min. In other cases I develops a higher neg. value in 30–60 min., while II, which has a high pos. value before sucrose administration, falls to 0 or a low neg. value in 30–60 min. These differences in reaction are explained by the suggestion that the 1st type of case still has relatively active insulin (III) secretion, which lowers the sugar content of venous blood, while the 2nd type of case is no longer capable of secreting III, with the result that the venous blood is higher in sugar than is the arterial blood. S. A. K.

The local and general action of aqueous solutions of carotene. V. M. Kushko and A. A. Mamontova. *Klin. Med.* (U. S. S. R.) **16**, 562–3(1938).—The parenteral injection of aq. colloidal solns. of carotene has the same effect as peroral administration in oil, provided the aq. soln. is freshly prepd. and is still yellow. The solns. decolorize on exposure to air for some time, and are no longer effective. S. A. Karjala

Blood, urine and gastric juice chloride in experimental scurvy. G. K. Kasasev. *Klin. Med.* (U. S. S. R.) **16**, 1750–6(1938).—No differences in total acidity were observed in the gastric juice of healthy and scorbutic guinea pigs, but the latter had considerably less free HCl in the juice. Blood Cl falls 9% and urine Cl increases 29% on the av. S. A. Karjala

Attempt to analyze the symptoms of polyneuritis in vitamin B_1 deficiency in the light of the chemical theory of the nervous process. Kh. S. Koshtoyants. *Compt. rend. acad. sci. U. R. S. S.* **24**, 357–9(1939)(in English).—Expts. made on the skeletal muscles of normal and vitamin B_1-deficient pigeons throw light on the processes underlying the disturbance of the neuroreflectory processes resulting from vitamin B_1 deficiency. Lack of vitamin B_1 (cocarboxylase) leads to a disturbance in the decompn. of carbohydrates, arresting it at the stage of pyruvic acid, which in turn disturbs the normal level of syntheses of the chem. factors involved in the nervous process, especially acetylcholine. 5 references. A. H. Krappe

The influence of total B avitaminosis and of alimentary carbohydrate disequilibrium on oxidation-reduction factors as glutathione and ascorbic acid in the pigeon. Raoul Lecoq and Élhane Flender. *Bull. sci. pharmacol.* **46**, 387–94(1939); cf. *C. A.* **33**, 8245[9], 8703[8].—Diet lacking in vitamin B or contg. 66% of glucose or galactose produces an increased glutathione content in the spleen, atrophy of the latter and increased elimination of bile pigments. A drop in muscle glutathione occurs every time when a grain diet is substituted by an artificial diet. The latter leads to a loss in ascorbic acid in liver, kidneys and spleen regardless of the presence of this factor in the diet. A. E. M.

Biochemical studies on B_1-avitaminosis in animals and man. Birger Carlström, Karl Myrbäck, Nils Holmin and Alvar Larsson. *Acta Med. Scand.* **102**, 175–213; *Biedermanns Zentr. B. Tierernahr.* **11**, 322–56(1939).—Numerous cases (human and animal) are discussed which are considered to represent vitamin B_1 deficiency according to the pathol. findings and the effect of administered thiamine. Pyruvic, lactic and (occasionally) α-glutaric acid, β-hydroxybutyric acid, total acetone and bisulfite-binding substances in the blood were detd. The study was made on a fox with deficiency disease, acetonemic cattle, horses with paralytic myoglobinuria, polymyositis and with encephalitis, and on human subjects with muscular insufficiency, chronic polyarthritis, chronic muscular rheu-

matism, hyperemesis gravidarum, pregnancy toxemia, etc. There was always an increase in the blood pyruvic and frequently an increase in lactic acid. The acetone bodies were greatly increased but in some cases there was no increase at all. In cattle acetonemia the α-ketoglutaric acid content was sometimes increased. Since treatment with thiamine caused a disappearance of the clinical symptoms and a return of the blood to a normal condition, these cases are regarded as B_1 deficiencies. S. Morgulis

Vitamin A and lung infection. Martin Uddströmer. *Acta Med. Scand.* **102**, 214–42(1939).—The designation of vitamin A as the "anti-infection" vitamin is without justification. Although a certain lowering of resistance of the respiratory passages to infection may be present, it is not at all certain that such a condition results from a mild deficiency of vitamin A, and the consumption of large amts. of A does not give any advantage. S. Morgulis

The influence of variations in nutrition on formation of acetaldehyde in the liver. I. Formation of acetaldehyde in the liver of dogs nourished on a normal mixed diet. Kokusyo Ri. *J. Biochem.* (Japan) **30**, 251–63(1939).—Adult dogs were on a diet consisting of beef, lard and boiled rice. They were killed by bleeding and the fresh liver was perfused with the same (defibrinated) blood. Acetaldehyde is formed in the liver; it differs with each individual, but the formation bears no relation to the concn. of Na_2SO_4 used. An increase in the formation of acetaldehyde was found when glucose or fructose was added but not glycogen or lactose. The addn. of insulin does not seem to affect the formation of acetaldehyde. S. Morgulis

Alimentary exudative diathesis and its relation to vitamin E. Henrik Dam and Johannes Glavind. *Skand. Arch. Physiol.* **82**, 299–316(1939).—See *C. A.* **33**, 5460[9]. S. Morgulis

Iron metabolism in the rat. Sam. Nordfeldt. *Skand. Arch. Physiol.* **83**, 7–38(1939).—Mature female rats on a low milk diet were in neg. Fe balance, the av. daily loss being 27–31 γ per day. Adding Ca lactate to the diet for a period of 5–7 weeks caused a very considerable increase in the daily Fe loss. The Fe balance was apparently not affected either by Cu or Co or by the addn. of Cu + Co. The daily feeding of 1000 γ Cu + 500 γ Co increased the hemoglobin and red-cell count. Even with rats, whose liver Fe store was 4–5 times as large, the results were essentially the same, though the loss of Fe in the feces was larger. S. Morgulis

The ability of hedgehogs to utilize carotene and vitamin A. Paavo Suomalainen. *Skand. Arch. Physiol.* **83**, 104–12(1939).—Hedgehogs were fed for 2 months a diet free from carotene and vitamin A. The carotene content of the liver and especially of the serum decreased. The vitamin A content of the serum decreased also but that of the liver remained unchanged. Feeding vitamin A to these animals causes a slight rise in the serum but a very substantial rise in the vitamin A content of the liver about half of the amt. fed being deposited there. Feeding carotene causes the carotene content of both serum and liver to increase several times. About 3% of the carotene fed is deposited in the liver. Although the vitamin A content of the liver on feeding carotene is likewise increased, it is not anywhere as great as when vitamin A is fed. Whether this is due to poor absorption of carotene or to an inefficient utilization of carotene in the formation of vitamin A has not been established. S. Morgulis

Geographical distribution of megacolon. Eduardo Etzel. *O Hospital* **16**, 445–55(1939).—A study of the geographical distribution of 626 cases of megacolon in Brazil from 1920 to 1938 established that the disease attacks especially zones of an ancient and poor civilization where there is a great possibility for an alimentary deficiency in vitamin B_1 (northeastern zone of the State of São Paulo bordering the State of Minas Gerais). No case was reported from the Atlantic coast, where fish rich in vitamin B_1 are abundant in the diet. G. Nachod

Megacolon and the present state of the theory of B_1 avitaminosis. Eduardo Etzel. *O Hospital* **16**, 611–17(1939).—Statistics of 626 cases, nearly all of them Brazilian farmers, confirm the theory that megacolon is caused by chronic B_1 avitaminosis. The disease is most common in puberty and below 40 years. G. Nachod

Metabolism of vitamin C in the human organism. A survey of the problem. Vicente Baptista. *O Hospital* **16**, 771–91(1939).—A summary. George Nachod

Hypovitaminosis B_1 and cardiopathies. I. The role of vitamin B_1 deficiency in the pathogeny of cardiovascular disorders in chronic alcoholics. Georges Bickel. *Arch. maladies coeur vaisseaux* **32**, 657–68(1939).—Early administration of vitamin B_1 in chronic alcoholics has the same beneficial effect on the cardiac disorders present as on the polyneuritic symptoms. A review with 45 references is included. **II. The role of vitamin B_1 deficiency in the pathology of cardiac disorders of pregnancy.** *Ibid.* 769–79.—Parenteral administration of vitamin B_1 is recommended in certain cardiovascular disorders of pregnancy. One case is described and 38 references are appended. J. Pinchack

The concentration of vitamin C in the blood during and after pregnancy. A. Sadovsky, D. Weber and E. Wertheimer. *J. Lab. Clin. Med.* **25**, 120–31(1939).—For percentage concn. of vitamin C in the blood of women (pregnant, post partum and nonpregnant) see *C. A.* **33**, 211[5] (information repeated in *J. Lab. Clin. Med.* paper). The blood of pregnant women with healthy teeth contained on the av. a slightly higher concn. of vitamin C than that of those with poor teeth. In this group the concn. of the blood Ca and P was found to be independent of the dental condition. The concn. of the vitamin was found to be low in the blood of severe cases of hyperemesis gravidarum, to be normal in the blood of pregnant women suffering from gingivitis, and slightly below normal when the gingivitis was complicated by caries. The concn. of vitamin C in human milk was found to be low immediately after parturition and continuously increases from the first day, the quantity excreted in the milk per day on the second day was calcd. to be 2.4 mg. and on the eighth day 27 mg. The vitamin C concns. of the milk and blood were not found to be definitely correlated and are not influenced by the age of the mother, the no. of children previously born or the wt. of the newborn infant. The importance of the estn. of vitamin C level in the blood for the exact diagnosis of a real vitamin deficiency is emphasized. Results, showing the effect of pH and KCN on the stability of vitamin C, the inhibition of the oxidation by serum protein, the failure of the addn. of oxalate to tested plasma samples to inhibit oxidation, and the loss of practically all reducing power in serum toward Tillmans reagent after ascorbic acid was removed by oxidase, are given. Howard W. Robinson

Vitamin A deficiency: Its prevalence and importance as shown by a new test. L. Bradley Pett. *J. Lab. Clin. Med.* **25**, 149–60(1939); cf. *C. A.* **33**, 2567[6].—Details of a rapid visual test depending on the recovery time after looking at a bright light are given. The test is shown to be related to vitamin A by experimentally induced vitamin deficiency, prolonged recovery time observed in patients with liver disease or on special diets, recovery on treatment of 200 cases classed as deficient and subjective improvement in many. Sex, age, color of eyes, myopia, hyperopia, astigmatism, wearing of spectacles and fatigue have no effect on the test. The influences of size of pupil, disparity of vision of the two eyes and disease are discussed. In a group of 1600 people, 52% were deficient in vitamin A, the incidence was higher in the unemployed. Adults tend to become more deficient in February than they were in October. Howard W. Robinson

Protein requirements of work horses at rest and during gradually increased work. II. Herbert Nitsche. *Biedermanns Zentr. B. Tierernahr.* **11**, 245–72(1939).—The need for protein does not increase in proportion to the increase in work. At 500,000 m.-kg. 80 g. of pure protein is needed but at 1,200,000 m.-kg. only 50 g. is needed. Felix Saunders

Long-time feeding of rats with yeast grown on the sulfite waste from cellulose manufacture. E. Mangold, A. Columbus and H. Hock. *Biedermanns Zentr. B. Tierer-*

nähr. **11**, 357–69 (1939).—Three generations of rats were fed with yeast grown on sulfite waste. The yeast contained 18% protein. In spite of the rather large amts. of Pb, Cu and As that the yeast contains neither the parent rats nor the 2 succeeding generations showed any signs of injury. Felix Saunders

Clinical and chemical observations on adrenalectomized dogs maintained by a diet high in sodium salts and low in potassium. R. A. Cleghorn, C. W. J. Armstrong and D. C. Austen. *Endocrinology* **25**, 888–98(1939).—The results of efforts to maintain 10 adrenalectomized dogs on a high-NaCl, low-K diet are reported. The difference in the development and in the signs of ordinary adrenal insufficiency and the crisis of salt-maintained dogs is emphasized. The clinical signs of the latter are correlated with the blood chemistry and pathol. findings. An expt. is reported in which K administration led to a crisis without the occurrence of a diuresis. The serum K increase in this and other expts. is often less than that to be expected from the blood water loss. Felix Saunders

Anorexia nervosa. Helen P. Davis. *Endocrinology* **25**, 991–5(1939).—The extent to which the activity of all organs of the body is reduced when faced with chronic undernutrition is clearly demonstrated. Thyroid ext. and pituitary gonadotropic ext. do not appear to have a beneficial effect in this condition. Felix Saunders

Renal rickets. A. Loeschke. *Monatsschr. Kinderheilk.* **78**, 298–328(1939).—A clinical, pathol. and chem. study was made in a girl 6 years old with the pyuria-type of renal dwarfism with severe rickets. Nonprotein N of the blood was 100–170 mg. %, serum NaCl 643–732 mg. %, serum Ca 8.7–5.7 mg. %, serum P 3.8–9.1 mg. %, CO_2-combining power of the plasma 38% by vol., blood sugar 103 mg. % and hemoglobin 52–23%. The Ca balance was ±0; the P balance, however, was strongly positive (+14% of the intake). The Ca was almost all eliminated through the stool, whereas the P output was equally divided between the urine and stool, a diversion to the stools which is characteristic also of simple florid rickets. When 0.5 g. Na_2HPO_4 per kg. of body weight was given by mouth the urinary and stool excretion of P was increased by about 130% in 2 normal control children and by 26.9% in the child with renal rickets; there was retention of P in the tissues. Post-mortem tissue analyses are given. Dysmineralization occurred in addn. to demineralization Since P retention, renal acidosis, hypocalcemia, and parathyroid hyperplasia do not, per se, lead to the development of true rickets, it is concluded that renal rickets is a genuine D-avitaminotic rickets modified only in certain aspects by the presence of chronic kidney disease (the dwarfism being not caused by, but coördinated to the congenital anomaly of the renal tract). H. P. G. Seckel

The role of nutritional factors in embryology. II. Is the role of the hypophysis identical during starvation and during avitaminosis B? S. I. Teresa. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 354–6(1937)(in German); cf. *C. A.* **32**, 7080⁹.—A group of mature rats was starved and another fed a vitamin B-deficient diet. Their hypophyses were then implanted in young female rats. The tissues from vitamin B-deficient rats showed no gonadotropic effect while the others did. Walter H. Seegers

Diet and the insulin content of pancreas. C. H. Best, R. E. Haist and Jessie H. Ridout. *J. Physiol.* **97**, 107–19 (1939).—Fasting or the feeding of diets rich in fat produces a very definite decrease in the insulin content of the pancreas. The insulin content of the pancreas, depleted by fasting, is restored within 6 days to a normal value by feeding a well-balanced diet. Carbohydrate alone effects a partial restoration but fat produces no rise in insulin content. Short periods of anesthesia and vitamin B_1 deficiency do not appear to affect the insulin content of the pancreas in a specific manner. The possible relationship between the low insulin content of the pancreas and the altered carbohydrate metabolism of animals which have been fasted or fed diets rich in fat is discussed.

E. D. Walter

Reduction of the *d*-amino acid oxidase content of rat tissues in riboflavin deficiency. A. E. Axelrod, H. A. Sober and C. A. Elvehjem. *Nature* **144**, 670–1(1939).—Rats fed on a diet low in both riboflavin and factor W show a decrease in the *d*-amino acid oxidase content in the liver. When the basal ration was supplemented with riboflavin alone or a factor W concentrate alone, there was some increase in the oxidase content of the liver, but the value returned to normal only when both riboflavin and the factor W concentrate were given. E. D. Walter

Flavin-adenine-dinucleotide in tissues of rats on diet deficient in flavin. S. Ochoa and R. J. Rossiter. *Nature* **144**, 787(1939).—A decrease of the flavin-adenine-dinucleotide of Warburg and Christian (*C. A.* **33**, 1882)' was found in the heart and liver of rats fed on a diet deficient in flavin. This is evidence of a further instance of a deficiency in the vitamin B complex affecting biol. oxidation systems. E. D. Walter

Effect of dietary protein on the course of nephrotoxic nephritis in rats. Lee E. Farr and Joseph E. Smadel. *J. Exptl. Med.* **70**, 615–27(1939).—Acute nephritis of medium severity, affecting both glomeruli and tubules, was produced in rats by injection of rat-kidney antiserum, given on 3 consecutive days. The course of the nephritis was markedly influenced by the type of diet which was fed. Rats tended to recover promptly from the induced nephritis when a low-protein, high-carbohydrate diet was given. On the other hand, in nephritic rats maintained on a medium-protein diet the nephritis almost invariably became chronic and half of the animals died of renal insufficiency during the 10.5 months of observation. Finally none of the rats which received a high-protein, low-carbohydrate diet recovered from the acute renal injury; all developed chronic progressive nephritis and the majority died of renal failure after some months. HOMER W. SMITH

New research on the variations in the inorganic constituents of the liver of the rabbit. I. Total variations in the inorganic constituents. S. Lazard-Koloduy. *Ann. physiol. physicochim. biol.* **15**, 392–402(1939); cf. *C. A.* **32**, 7522⁸, 9206⁶; Chevillard and Mayer, **33**, 8734⁹, 8735². —In rabbits of the same breed, living under uniform conditions and on the same diet the quantity of inorg. constituents in the liver can differ from one individual to another but their concn. varies very little. This phenomenon is true if the quantity of ash is related to the mass of the liver or to the mass of H_2O in the liver. The variations in the inorg. constituents are not produced separately but follow those of the other constituents of the liver. This stability of the concn. persists during changes in the diet, upon the infliction of wounds, during existence under conditions of varied caloric loss or upon the injection of various substances, as saline, glucose, oxalic acid, citric acid, adrenaline and acetylcholine. The concn. of inorg. constituents in the liver of the rabbit varies little during the 1st 24 hrs. of fasting, but increases slightly if the fasting is prolonged. **II. Variations in potassium, sodium and calcium.** *Ibid.* 403–10.—In normal rabbits of the same breed, age and wt. rather large individual variations exist in the contents of K, Na and Ca in the liver. The Ca content is smallest and shows the greatest fluctuations. Like the concn. of the ash, the concns. of K and Na (and probably Ca) vary little from the av. During fasting or overfeeding K and Na vary in the same sense as the ash. The concns. of K and Na with respect to the liver tissue vary little when the mass of the latter changes. Variations in the mass of the liver depend on the movements of H_2O, inorg. and org. constituents; K, Na and Ca appear to follow these movements. Ruth Berggren

Animal experiments on oxygen lack and asphyxia. I. The circulation and respiration during oxygen lack. W. Mertens. *Arch. Kreislaufforsch.* **2**, 192–209(1938).—The significance of the presso-receptor and vagus regulations during O lack was studied in morphinized and urethanized dogs by means of a rebreathing app. After exclusion of the presso-receptors and vagi only a smaller degree of O lack is obtained. The O consumption is greater, while the respiration remains unchanged. The blood pressure falls. The O_2 content of the arterial blood decreases and the CO_2 content increases. If the presso-receptors and vagi are intact, 3 conditions (no change, primary rise or precritical fall in blood pressure) are discernible in Phase I (a decrease in tonus in the region of the sympathetic and parasympathetic nerves). Upon exclusion of the vagi with retention of the presso-receptors the primary rise in blood pressure is absent. The increase in respiration occurs mainly through an increase in amplitude. The O_2 and CO_2 contents of the arterial blood decrease. The degree of O lack is as high as when the vagi are retained. Upon exclusion of the presso-receptors with retention of the vagi the vagus stimulation appears very early. The respiration shows only a small increase in frequency. The CO_2 content of the arterial blood increases slightly. In the case where the vagi are retained, the cessation in respiration always occurs simultaneously with the max. stimulation of the vagus at the end of Phase II (a chemically produced condition of stimulation of the vegetative nerve centers). After exclusion of the vagi, however, the cessation of respiration appears simultaneously with the final fall of blood pressure in Phase III (a central paralysis, initially reversible). **II. Circulation and respiration during asphyxia.** H. Rebensburg. *Ibid.* **5**, 123–34 (1939).—The effect of the presso-receptor and chemo-receptor nerves and of the vagi during gradual asphyxiation was estd. on narcotized dogs with the aid of a rebreathing app. without CO_2 absorption. After exclusion of all these nerves the av. arterial blood pressure decreases progressively during asphyxiation; the heartbeat rate remains unchanged until the heart action is arrested; at first the respiration increases solely through increase in amplitude, the frequency remaining unchanged, but later the respiration ceases at about the same time as the heart action. If all the nerves are retained, the blood pressure and heartbeat rate, as a result of reflex counter-regulations, remain unchanged until the inspired air contains about 5% CO_2 and 12.5% O_2; then both increase and reach a peak at about 9.5% CO_2 and 4.5% O_2, after which they fall off rapidly. The blood-pressure peak is connected with the presence of the chemoreceptors and is lower when the presso-receptors are also retained. The respiratory min. vol. increases considerably as a result of the increase in amplitude and frequency; its peak is attained only at a higher CO_2 content of the blood than when the nerves are excluded. If only the vagi are excluded, the blood pressure still reaches an asphyctic peak; the frequency of the respiration remains unchanged, while the amplitude increases. If only the CO_2 is increased in the inspired air, while the O_2 is kept above 20%, neither the blood pressure nor the heartbeat rate increases; they increase immediately, if the O_2 supply is discontinued.
Ruth Berggren

Clinical and experimental studies on the water metabolism. V. The bound and free water of the serum of rabbits during water deficiency. Tokikane Okamoto. *Oriental J. Diseases Infants* **23**, 4(1938)(in English).—The bound and free H_2O of the serum of adult male rabbits were detd. before and after starvation or feeding a dried, powd. diet. During H_2O deficiency the total H_2O content as well as the percentage of free H_2O in the blood is lower, while the percentage of bound H_2O is higher, than normal. During dehydration the living organism loses free H_2O more readily than bound H_2O. **VI. Changes in the bound and free water in rabbits with active serum anaphylaxis.** *Ibid.* 1–3.—In the serum and pressed fluids of the muscles and livers of rabbits sensitized with horse serum the percentage of bound H_2O increases and that of the free H_2O decreases as the incubation period advances; in the liver the percentage of free H_2O increases and that of the bound H_2O gradually decreases. These changes reach a max. during the 2nd week of incubation and then return to normal, although normal values are not reached at the end of the 3rd week. If shock is produced by again injecting horse serum after the 3rd week of sensitization, the percentage of bound H_2O in the serum and liver fluid increases markedly and that of the free H_2O decreases, while in the muscle fluid the reverse is true. The total H_2O content of the serum, muscle and liver during sensitization does not change markedly. But on the appearance of shock the total H_2O content of the blood decreases and that of the muscle and liver increases; on the 1st day after the shock the values become approx. normal and then approach those during the incubation period. The changes in the H_2O metabolism during shock are attributed to the increase in permeability of the blood vessels. The colloid-chem. change in the body during incubation and shock is accompanied by the change in the H_2O metabolism.
Ruth Berggren

Physical chemistry of the blood during hypnotic conditions. A. Naerebout and Berthold Stokvis. *Nederland. Tijdschr. Geneeskunde* **83**, IV, 5532–40(1939).—The authors det. in the blood: Cl, Ca, urea, glucose, red blood cells, leucocytes and sedimentation, all before and after sedative medication. No effect of this medication was found.
R. Beutner

Necessity of magnesium in the pyruvate oxidation system of brain. S. Ochoa. *Nature* **144**, 834(1939).—Pigeon brain prepns. treated with $Na_4P_2O_7$ and dialyzed for 8 hrs. give with pyruvate 1/2 of the O uptake which can be obtained by the addn. of Mg. Mn also has a striking effect.
Rachel Brown

The biological activity of crystalline cortin-like substances. L. Waterman, M. Danby, J. H. Gaarenstroom, R. W. Spanhoff and I. E. Uyldert. *Acta Brevia Neerland. Physiol. Pharmacol. Microbiol.* **9**, 75–8(1939).—The activity of 10 cortin-like substances was detd. by (1) the dog test (I) (U., *C. A.* **34**, 1081[8]), (2) the swimming test on adrenalectomized rats (II) (*C. A.* **31**, 2664[8]) and (or) the muscle test of Everse and Fremery (III) (*Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* 2, 152 (1932)). In I pos. results were obtained with 1 1/2 mg. of the partially hydrolyzed ketone fraction C17A2 (Reichstein) (IV), 0.6 mg. corticosterone (V), 2 mg. corticosterone acetate, 2 mg. corticosterone butyrate (VI), 2 1/2 mg. 21-hydroxypregnenolone (VII), 5 mg. substance E (Reichstein) (VIII), 1 1/4 mg. substance M (Reichstein) (IX) and 1/8 mg. (usually) with desoxycorticosterone acetate (X). Neg. results were given in I by 6 mg. corticosterone benzoate (XI), 1 mg. VII, 3 mg. VIII, 1/16 mg. X and 12 mg. progesterone. In II uncertain results were obtained with IV, pos. results with 1/2 mg. V, 2 mg. XI, 1 mg. VI, 3 mg. IX, 1/2 mg. X; neg. results were obtained with 1/4 mg. V, 3 mg. VII, 2 mg. VIII, 2 mg. IX and 3/4 mg. X. In III 1.2 mg. V gave pos. results, and 600 γ gave neg. results. With IX 2 mg. was pos. and 1 mg. neg.; with X 80 γ was pos. and 40 γ neg.
E. Curzon

The physiological control of the normal human gastric secretory curve. Chas. M. Wilhelmj and Adolph Sachs. *Am. J. Digestive Diseases Nutrition* **6**, 467–74(1939).—Acid inhibition and duodenal regurgitation play important roles in the regulation of the gastric secretory curve in the normal human subject.
Edward Eagle

The calcium content of gastric juice. Jos. B. Kirsner and J. Edmond Bryant. *Am. J. Digestive Diseases Nutrition* **6**, 704–6(1939).—The av. Ca content of gastric juice at pH 1.49 to 1.91 was 2.06 mg. %; gastric juice with a pH between 2.0 and 2.94 averaged 2.12 mg. %; the av. Ca content of gastric juice with pH 3.05 to 8.38 was 4.54 mg. %. Thus, the higher the pH value of the gastric juice, the higher the amt. of Ca. Ewald test meal and fasting gastric juice contain more Ca than histamine-stimulated secretion.
Edward Eagle

Changes in the lipide-albumin and lipide-globulin complexes during aging of blood serum. M. Mousseron and H. Huc. *Compt. rend. soc. biol.* **132**, 151–2(1939).—When

serum is allowed to stand a week at 0–17° the amt. of lipide fixed to the albumin fraction remains const. but that fixed to the globulins increases slightly. L. E. Gilson

Ascorbic acid content of eyes of various species of [domestic] animals. R. Vladesco and H. Stefanesco. *Compt. rend. soc. biol.* **132**, 169–71(1939).—The results agree with those of other investigators. L. E. Gilson

Influence of age on blood potassium. G. Benetato and P. Ciurdariu. *Compt. rend. soc. biol.* **132**, 175–7 (1939).—Serum samples were taken 3 hrs. after the blood had clotted. Serum of rats 8–9 months oil contained an av. of 31.5 and that of rats 2 yrs. old 39.2 mg. % K. Serum of men and women 19–22 yrs. old contained 21.4 and serum of men past 70 yrs. 32.4 mg. % K. **Influence of age on tissue potassium.** *Ibid.* 177–8.—Brains of young rats contained an av. of 0.4 and brains of old rats 0.32% K. Muscles of young rats contained 0.4 and those of old rats 0.36% K. L. E. Gilson

Total chloride and sodium chloride of renal tissue after extirpation of the adrenals [in rats]. Mares Cahane. *Compt. rend. soc. biol.* **132**, 178–80(1939).—After adrenalectomy total Cl increased slightly, NaCl decreased slightly. L. E. Gilson

Integration of the vasomotor responses in the liver with those in other systemic vessels. L. N. Katz and S Rodbard. *J. Pharmacol.* **67**, 407–22(1939).—The dynamic interrelationships between the blood flow in the thoracic inferior vena cava and the portal vein and the arterial, venous and portal pressures were studied in the intact anesthetized dog and the effects of adrenaline, histamine, pitressin, amyl nitrite, acetylcholine, mecholyl, atropine, saline soln. and vagus section on the flow in the hepatoportal and systemic circuits detd. L. E. G.

Effect of desoxycorticosterone acetate on blood sugar and electrolytes of adrenalectomized rats. Harold E. Harrison and Helen Coplan Harrison. *Proc. Soc. Exptl. Biol. Med.* **42**, 506–8(1939).—The injection of adequate amts. of desoxycorticosterone acetate into fasted adrenalectomized rats prevents the drop in blood sugar which occurs in untreated adrenalectomized rats but the amt. required to maintain the blood sugar is greater than that necessary to maintain normal concns. of serum electrolytes and nonprotein N. L. E. Gilson

Factors influencing ovarian response of normal and hypophysectomized rats to pregnant mare serum. Richard I. Pencharz. *Proc. Soc. Exptl. Biol. Med.* **42**, 525–9 (1939).—With small doses intraperitoneal injection was twice as effective as subcutaneous in all the rats. In the normal rats pregnant mare serum was twice as effective as in the hypophysectomized rats, in producing increase in the wt. of the ovaries. The uterine response was not significantly affected by the mode of injection in normal rats, but in the hypophysectomized rats intraperitoneal injection was 4 times as effective as subcutaneous.
L. E. Gilson

Maintenance of gestation in the castrate pregnant rat with androgens. R. R. Greene and M. W. Burrill. *Proc. Soc. Exptl. Biol. Med.* **42**, 585–7(1939).—Testosterone, testosterone propionate and androstenedione maintained pregnancy with resulting living fetuses in rats castrated during the latter half of pregnancy. In rats castrated before the 11th day all the fetuses were resorbed.
L. E. Gilson

Responses of hypophysectomized immature female rats to mare serum hormone. J. H. Leathem. *Proc. Soc. Exptl. Biol. Med.* **42**, 590–2(1939).—Small doses of mare serum hormone ("Gonadin") produced increase in ovarian wt. and marked theeal luteinization. Larger doses caused the development of large vesicular follicles and the largest doses used (50 rat units) caused the formation of corpora lutea, many of which were atretic, follicles with thickened granulosa and some large normal vesicular follicles. Large amts. of castrate urine ext. also produced corpora lutea, but produced only follicle stimulation in the absence of theeal luteinization in ovaries weighing as much as 80 mg. Thus a definite difference in the gonadotropic activity of mare serum hormone and castrate urine is seen under identical exptl. conditions. L. E. Gilson

Prothrombin, thromboplastin and thrombin; quantitative interrelationships. Edwin T. Mertz, Walter H. Seegers and H. P. Smith. *Proc. Soc. Exptl. Biol. Med.* **42**, 604–9(1939); cf. *C. A.* **32**, 8464[8]; **33**, 8633[6].—Methods are described. Thromboplastin is consumed when it reacts with prothrombin in the presence of ionic Ca; hence it is not an enzyme capable of converting an unlimited quantity of prothrombin into thrombin. The quantity of thrombin produced from an excess of prothrombin is proportional to the quantity of thromboplastin added. If thromboplastin is present in excess the amt. of thrombin formed is proportional to the amt. of prothrombin added.
L. E. Gilson

Assay of progesterone by intrauterine application in the rabbit. Arthur L. Haskins, Jr. *Proc. Soc. Exptl. Biol. Med.* **42**, 624–8(1939).—The findings of McGinty, *et al.* (*C. A.* **33**, 6930[3]), were confirmed. L. E. Gilson

Correlation between movements of gravid uterus and formation of histamine. H. Handovsky. *Proc. Soc. Exptl. Biol. Med.* **42**, 643–5(1939).—Expts. with cats suggest that inside the pregnant uterus (in the placenta) a rhythmic production of histamine occurs, which provokes the contractions of the uterus, and that some of this histamine escapes destruction, passes into the general circulation, and causes the short but distinct falls of blood pressure observed at intervals of about 2 min.
L. E. Gilson

Effect of simultaneous administration of growth complex and estradiol on mammary glands of hypophysectomized rats. Ira T. Nathanson, Darrel T. Shaw and Clifford C. Franseen. *Proc. Soc. Exptl. Biol. Med.* **42**, 652–5(1939).—The effects were irregular and of uncertain significance. L. E. Gilson

The inclusion of adrenaline and of sympathins in the biochemical dynamics of the cells. A. M. Utevs'kiĭ. *Uspekhi Sovremennoĭ Biol.* **9**, No. 2, 203–29(1938); *Khim. Referat. Zhur.* **2**, No. 3, 55(1939); cf. *C. A.* **33**, 3427[7].—A no. of physicochem. changes produced in the cells by adrenaline bring about the transformation of glycogen. Oxidation of adrenaline in the cell to its *o*-quinone and adrenochrome is described; these products are biocatalysts in oxidation processes in the cell. W. R. Henn

Influence of androgens on the growth and metastasis of the Brown-Pearce epithelioma. J. R. Murlin, C. D. Kochakian, C. L. Spurr and R. A Harvey. *Arch. Path.* **28**, 777–98(1939); cf. *C. A.* **33**, 8783[6].—Rabbits inoculated in one testis with a fragment of Brown-Pearce epithelioma were treated with injections of the following androgens: urinary androgenic exts., androsterone, dehydroandrosterone, testosterone, testosterone propionate; also estradiol monobenzoate. The urinary androgenic exts., especially in the smaller doses, caused increased regression of the primary tumors. The same effect, however, could not be produced with androsterone or dehydroandrosterone, the known androgens of the urinary exts. It is suggested that this result may be due to some other steroid (or steroids) or a combination of substances in the ext. In the expts. continued after cessation of injections the urinary exts. and testosterone propionate decreased, testosterone increased and estradiol monobenzoate, sesame oil and olive oil left unaffected, the amt. of metastasis. In the short-period expts., however, androsterone, dehydroandrosterone and also testosterone propionate showed no or very slight effect. The greatest differences were noted when injections were begun prior to inoculation of the tumor. A hypothesis proposed to account for the opposite carcinogenic effects of androgens and estrogens is that estrogens owe their carcinogenic activity to the necessity for their oxidation, i. e., they tend to rob cells of O_2 and leave them dependent on anaerobic glucolysis. This action is prevented by androgens, which provide H acceptors, thereby adequately titrating the H which estrogens have to spare and thus defeating the attack on normal cell life. Harriet F. Holmes

A study of the pH values of the ingesta of the bovine rumen. C. F. Monroe and A. E. Perkins. *J. Dairy Sci.* **22**, 983–91(1939).—The pH values of the contents of the

bovine rumen obtained from animals having a rumen fistula were detd. The pH values of the ingesta averaged between 6.83 and 7.01 when such roughages as corn or A. I. V. silage and alfalfa hay in fair amts. were fed. On pasture, both blue grass and alfalfa, the ingesta were slightly more acid. Samples taken at 2-hr. intervals throughout the day showed the ingesta to be most alk. just prior to feeding in the morning. After feeding, there was a drop until about 9 A. M. and then a gradual trend toward alky. reaching a peak at 3 P. M. immediately preceding the evening feeding. After feeding there was again a drop in pH. These results were obtained for cows on winter rations. Those on pasture did not show these fluctuations. The pH values were not the same in all parts of the rumen. The largest variations were found after feeding. At 1 P. M. these variations fell within 0.2 pH. Samples of the rumen contents of animals slaughtered 12 to 18 hrs. after the last feeding had an av. pH value of 7.34 These values were uniformly more alk. than av. values of the rumen contents taken from living animals but were quite similar to those obtained at the 5 A. M. sampling in the 2-hr. collection study. A. H. J.

The differentiation of organ lipases in the blood. T. I. Meerzon. *Klin. Med.* (U. S. S. R.) **16**, 62–4(1938).—The addn. of an inactivated lipase or ext. of the liver to normal serum increases its stability to quinine (I) but not to atoxyl (II). The addn. of an inactivated ext. of the pancreas to normal serum does not affect its stability to I but increases its stability to II. S. A. Karjala

The normal ascorbic acid content of the blood. V. M. Ioskova. *Klin. Med.* (U. S. S. R.) **16**, 1582–4(1938).—The normal ascorbic acid content of the blood is 0.9–1.0 mg. % in the fall and 0.4–0.5 mg. % in the winter and spring. S. A. Karjala

Further investigations on the mechanism of the formation and destruction of the chemical factors of nervous stimulation. Kh. S. Koshtoyants and R. L. Mitropolitanskaya. *Compt. rend. acad. sci. U. R. S. S.* **23**, 955–7 (1939)(in English); cf. *C. A.* **33**, 5492[1].—Investigations on the transmission of stimuli from the nerve of the cardiac muscle under conditions of carbohydrate metabolism, inhibited by the effect of glyceraldehyde on the heart of a frog, showed that after treatment of the heart with glyceraldehyde (0.02 *M* soln.) the typical response (stopping) to the excitation of n. vagus is absent. This is explained by the assumption that the disturbance of the normal course of carbohydrate metabolism due to the action of glyceraldehyde led to the disturbance of the normal process of formation of acetylcholine-like substances. 4 references. A. H. Krappe

The role of diphosphoglyceric acid in the electrolyte equilibrium of blood cells: studies of pyloric obstruction in dogs. S. Rapoport and Geo. M. Guest. *J. Biol. Chem.* **131**, 675–89(1939); cf. *C. A.* **26**, 5141; **33**, 7868[1].—In studies of intestinal obstruction in dogs previously reported it was suggested that unidentified "ester P" compds. probably played an important role in maintaining the acid-base equil. of the blood. With a suitable method available for the detn. of diphosphoglyceric acid, these expts. have been repeated and the changes in concn. of org. acid-sol. P in the blood cells have been identified as occurring almost entirely in the diphosphoglyceric fraction. The most important factor compensating for the decreased concn. of Cl in the cells after pyloric obstruction was an increased concn. of diphosphoglycerate. In both normal dogs and those with obstruction good agreement was found between the cations (detd. as total base) and the sum of the anions Cl, HCO_3, hemoglobin, inorg. phosphate, diphosphoglycerate and other org. acid-sol. phosphate (mainly adenosinetriphosphate). The agreement between the distribution ratios calcd. from the data on the nondiffusible anions and the observed ratios of the diffusible H, Cl and HCO_3 ions indicates that the distribution of the diffusible ions between cells and serum depends mainly upon the concn. and anion equivalency of hemoglobin and diphosphoglycerate, the 2 most important nondiffusible constituents of the cells. This agreement also supports the validity of the Donnan theory as applied to dog blood under the conditions described. Thirty-seven references. A. P. Lothrop

The artificial activation of the testicles of some bird species in the fall by irradiation and anterior pituitary hormone. H. Schildmacher. *Biol. Zentr.* **59**, 653–7 (1939).—*Phoeniculus ph. phoenicurus*, *Sylvia a. atricapilla* and *Erithacus r. rubecula* were brought to complete or partial testicular activity by exposure to addnl. light in November, but not in the first half of October. Pregnant mare serum was only moderately successful, but in combination with the anterior pituitary synergistic hormone full activity was obtained. Since the hormone is successful also in October, it is concluded that the failure of light is not caused by lack of response in the testicle but to some other organ, probably the pituitary. A. E. Meyer

Blood in experimental asphyxia. (A cystine-cysteine study.) II. Asphyxia caused by breathing air containing an excess of carbon dioxide. Ryosuke Murata. *Japan. J. Med. Sci. III. Biophys.* **6**, 9–28(1939); cf. *C. A.* **32**, 9210[6].—A CO_2 content in the inhaled air exceeding 3.35% in the dog and 3.82% in the rabbit causes a marked increase of ventilation. The max. stimulation obtains at about 6%. The cystine-cysteine content in the blood decreases after about 30 min. but on prolongation of the expt. a considerable increase is observed. With increase of ventilation there is an increase of H-ion concn. and the CO_2-combining power of the blood increases at an av. Later, when the respiratory movement returns to normal, the pH shows no appreciable changes while the CO_2-binding power considerably increases. The change in respiration is stronger than that in asphyxia caused by lack of O_2. In the final stage, the respiration becomes weak and concomitantly the CO_2-binding power decreases again and the pH is augmented. The normal dissocn. curve of dog blood is lower than that in rabbit blood because the former has a lower alkali reserve. A. E. M.

A hormone of intestinal motility produced by the action of hydrochloric acid on the intestinal mucosa. T. Hukuhara and S. Kinose. *Japan. J. Med. Sci. III. Biophys* **6**, 73–5(1939)(in German).—While HCl introduced into the duodenum causes abundant secretion of pancreatic juice, the motility of the intestine is only stimulated by local irritation. A hormone similar to secretion does not exist. A. E. Meyer

The tonus of the vagus in affective psychosis investigated with neutral red. A. Amicarelli. *Neopsichiatria* **2**, (1936); *Rev. sudamericana endocrinolinmunol. quimioterap.* **22**, 731.—The secreting activity of the stomach was measured as an index of vagal tonus. After intramuscular injections of neutral red, the dye appears in the gastric juice within 12 min. in normal persons, at 8 min. in hyperacidity and after 25 min. in hypoacidity. Hypotony of the vagus exists in melancholia and in manic-depressive states; hypertony was found in anxiety states. A. E. Meyer

Oxygen consumption in vitro of different skeletal muscles. Nils Alwall. *Acta Med. Scand.* **102**, 258–74(1939).—The detns. were made in the Warburg app. with either strips of muscle or finely chopped muscle. The latter were in a phosphate buffer to which was added succinic or lactic acid, or boiled muscle juice. Under these conditions it was found that the O_2 consumption of the masseter muscle approaches that of the heart muscle which *in vitro* is ordinarily about 10 times as great as that of skeletal muscles. The O_2 consumption of other cranial muscles (tongue, eye), though less than that of the masseter, is still many times larger than the O_2 consumption of such muscles as the sartorius. S. Morgulis

Increase in citrate metabolism in vitro through salicylic acid. Nils Alwall. *Acta Med. Scand.* **102**, 390–6(1939).—The O_2 consumption of liver or kidney slices in the presence of citrate is increased by salicylic acid. This observation seems to offer an explanation of the lowering of serum citrate by medication with salicylates. S. Morgulis

Biochemical studies on carbohydrates. XLIX. Submaxillary mucin and mucoid. Yasuhisa Tanabe. *J. Biochem.* (Japan) **30**, 181–4(1939); cf. *C. A.* **33**, 9404[8],

1046[1].—The mucin and mucoid from the submaxillary are practically identical with material prepd. from the sublingual. L. **Prosthetic group of cornea mucoid.** Masami Suzuki. *Ibid.* 185–91.—The ratios of N:S (sulfate) for cornea mucoid were 2.76–3.42, resembling those found for mucoitinsulfuric acid. The carbohydrate complex apparently consists of more than one ordinary sugar. LI. **Carbohydrate grouping of the mucin from the vitreous humor.** *Ibid.* 193–8(1939).—Reducing power, glucosamine, glucuronic acid and acetyl were the same in vitreous humor mucin as in funis mucin. It contains practically no sulfate S or ordinary sugar. S. M.

Hibernation of the hedgehog. Carotene and vitamin A metabolism. Paavo Suomalainen. *Skand. Arch. Physiol* **83**, 94–103(1939).- The carotene and vitamin A content of the liver and serum were detd. in hedgehogs in the late summer while the animals are active, in the late fall when the animals become somnolent, in mid-winter when the animals are in deep sleep, and later when they commence to wake up, and again in early spring shortly after they have awakened from their hibernation. The liver vitamin A content diminishes in the course of hibernation, the decrease extending into the summer months. In spite of feeding the liver, vitamin A content actually attains its min. value during the late summer months, but as hibernation sets in there is a very great accumulation of vitamin A. In the serum, the vitamin A content reaches a min. just at the commencement of hibernation and a max. at the time of awakening. The carotene content of the serum is higher in the summer than during the hibernation. The vitamin A/carotene ratio, both in liver and serum, is much greater in the winter than in the summer. S. M.

The excitation mechanism of the chemoreceptors of the carotid body. U. S. von Euler, G. Liljestrand and Y. Zotterman. *Skand. Arch. Physiol.* **83**, 132–52(1939); cf. *C. A.* **33**, 8277[1].—The chemoreceptors of the carotid body (cat), judged by its action potentials, responds to O_2 want when the hemoglobin satn. falls below 96%, the response being practically in linear relationship to the arterial satn. CO_2 evokes a response when the alveolar tension is below 30 mm. Hg and increases regularly with rising tension. The centers are thus stimulated reflexly both by O_2 and CO_2 through the carotid body. Intravenous injection of very weak CN stimulates the chemoreceptors, and this effect can be quickly abolished by a small dose of NH_4OH or by raising the arterial O_2 satn. The stimulating action of nicotine or lobeline cannot be abolished by NH_4OH, which leads to the conclusion that these alkaloids must act on the chemoreceptors at a different point than O_2 lack or CO_2. S Morgulis

The chemical excitation of nerve cells. D. W. Bronk, Frank Brink and M. G. Larrabee. *Trans. Am. Neurol. Assoc.* **1939**, 46–9. J. Pinchack

Assay of cortical hormone. I. E. Uyldert. *Endocrinology* **25**, 871–6(1939).- -The assay of cortin in dogs based upon clinical symptoms, principally appetite and body temp., is described. The symptoms of insufficiency are sharply defined. The largest dose of ext. that can possibly be assumed to be pos. is tested first, then the dose is diminished until the dog becomes insufficient. The choice of assay period is arbitrary. A period of 4 days is sufficient for 1 dose of ext. It is necessary to det. the limiting dose in a large no. of dogs and to check this dose with the limiting dose of a known standard ext. Water-balance expts. are of little value for the assay, but from large nos. of estns. it is concluded that in insufficiency fluid excretion is increased in relation to fluid intake. F. Saunders

Repression and resorption of the corpora lutea of early pregnancy following injections of testosterone propionate. H. O. Burdick and Basil Emerson. *Endocrinology* **25**, 913–18(1939).—In mice, daily injections of 5 mg. testosterone propionate begun the day of mating cause the corpora lutea to become corpora albicans and hasten their resorption. The ovaries decrease in size. Similar treatment with 0.25 mg. for the same length of time results in larger ovaries but in small and degenerated corpora lutea. Temporary sterility is established with either amt.
Felix Saunders

Effect of large doses of testosterone propionate (oreton) on the female genital tract of the very young rat. Production of ovarian cysts. Harry Shay, J. Gershon-Cohen, Karl E. Paschkis and Samuel S. Fels. *Endocrinology* **25**, 933–43(1939).—Administration of large doses of testosterone propionate, beginning at the age of 1 day, produced ovarian tumors. The estrous cycle was not completely suppressed. It is thought that the testosterone has a direct effect on the female gonad. F. Saunders

Action of small quantities of progesterone. Oluf Thomsen, Kaj Pedersen-Bjergaard and Ib Anderson. *Endocrinology* **25**, 944–52(1939). --The appearance of the contracted type of uterus in rats that are used for gonadotropic hormone assays is dependent on whether developed corpora lutea are found in the ovaries. Dilated uteri are found in all animals when they are autopsied after 48, 60 and 72 hrs. After 96 hrs. all of the uteri are of the contracted type. The contracted uterus appears in a definite zone of varying quantities of progesterone, the dilated type of uterus being found not only over but also under the zone. The zone of action was found to be between 0.3 and 0.13 rabbit units. Felix Saunders

Relation of the melanophore hormone of the pituitary gland to oxygen consumption of the rat. R. S. Teague. *Endocrinology* **25**, 953–61(1939).—Prepns. of the pituitary gland rich in melanophore hormone, obtained from various sources and prepd. by different methods, vary considerably in their effect on O consumption in rats. A pituitary ext. of Collip and a melanophore hormone ext. prepd. from whale anterior lobe, although having a similar melanophore hormone content, showed marked differences in their action on O consumption in rats. Collip's ext. in large doses stimulated metabolism but the whale prepn. was inactive. When the melanophore hormone in pit-melanin was destroyed by HCl or by tryptic digestion, the product produced even more consistent metabolic stimulation than the original ext. The melanophore hormone of the pituitary gland is not identical with a substance in pituitary exts. which increases the basal metabolic rate.
Felix Saunders

Biological assay of the melanophore hormone of the pituitary gland. R. S. Teague. *Endocrinology* **25**, 962–4(1939).—A method for the biol. assay of the melanophore hormone of the pituitary is described. The hypophysectomized frog is used as the test object and alkali-treated U. S. P. posterior pituitary powder as the reference standard. A unit of melanophore hormone is defined as the activity of 1 γ of the alkali-treated standard, when injected into a 30-g. hypophysectomized frog. F. S.

Effects of hypophysectomy upon the blood picture of the rat. Erwin P. Vollmer, Albert S. Gordon, Irving Levenstein and Harry A. Charipper. *Endocrinology* **25**, 970–7(1939).--Complete hypophysectomy in the rat is invariably followed by a decline in red cell count and hemoglobin, which attain 60–70% of their normal values in approx. 2 months. Felix Saunders

Separation of follicle-stimulating fraction from pituitary gonadotropin. H. Rinderknecht and P. C. Williams. *J. Endocrinology* **1**, 117–27(1939).—Attempts to sep. a pure follicle-stimulating fraction from horse pituitary exts. by the methods of Evans, *et al.* (cf. *C. A.* **31**, 3120[2]) and of Fevold (cf. *C. A.* **33**, 5430[6]) were unsuccessful By modifications of these procedures a relatively pure follicle-stimulating fraction was obtained. Removal of inert material from the crude pituitary gland exts. improved the results. The inert materials in crude exts. may seriously interfere with the sepn. of LH and FSH.
Felix Saunders

Effects of continuous oral administration of aqueous diethylstilbestrol solutions to rats. R. L. Noble. *J. Endocrinology* **1**, 128–41(1939).—By substituting aq. solns. of different concns. of stilbestrol for rats' drinking water it is possible to administer this substance at various dose levels for prolonged periods of time. In adult male animals a daily dose of 2–3 γ caused a slight but definite inhibition of body growth, whereas atrophy of the gonads was not produced until a daily dose of approx. 7 γ was given. Lactation was reduced by a daily dose of 2–3 γ.

Larger doses of stilbestrol were followed by enlargement of the adrenals and pituitary gland, marked atrophy of the gonads and extreme alterations in body growth and lactation. A reduction in fluid intake occurred in adult rats after the oral administration of aq. solns. of stilbestrol, after implantation of crystals or after hypophysectomy. Felix Saunders

Duration of action of certain natural and synthetic estrogens when administered orally or by injection. C. W. Emmens. *J. Endrocinology* **1**, 142–55(1939).—Large doses of estrone injected daily during the post-ovulation phase of the menstrual cycle of the pig-tailed monkey lead to swelling of the sexual skin. The swelling is due to the accumulation of water in the skin. The fact that swelling does not occur during this phase of the normal cycle shows that the progesterone produced by the corpus luteum is unable to retain in the sexual skin the water deposited there as a result of estrogenic stimulation during the pre-ovulation phase. Testosterone and cortin injected into spayed monkeys do not lead to the retention in the sexual skin of water that has accumulated there as a result of previous injections of estrone. The injection of vasopressin at short intervals delays the resorption of sexual skin swelling. Neither cortin nor vasopressin is able to inhibit post-estrogen bleeding in monkeys. Felix Saunders

Rate of appearance of antiluteinizing activity in the serum of rabbits injected with extract of ox pituitary gland. I. W. Rowlands. *J. Endocrinology* **1**, 172–6(1939).—The serum of rabbits injected daily with a gonadotropic ext. of ox pituitary gland inhibits selectively, in immature rats, the luteinizing activity of a gonadotropic ext. of gelding pituitary gland. The amt. of antiluteinizing activity present in the serum increases up to about 7 weeks after the commencement of immunization, is const. during the next 2 weeks, and then falls somewhat. Felix Saunders

Progonadotropic and antithyrotropic activity of antiserums to extracts of the anterior pituitary gland. I. W. Rowlands. *J. Endocrinology* **1**, 177–83(1939).—The serum of a dog injected daily for many weeks with an ext. of ox pituitary gland augmented the gonadotropic activity of exts. of ox and pig pituitary gland when tested on the ovaries of immature rats. The serum neither augments nor inhibits the thyrotropic activity of the ext. used for immunization. The serum of a goat injected with an ext. of pig pituitary contg. thyrotropic and gonadotropic activity augmented the response produced by this ext. in the ovaries of the immature rat. The progonadotropic activity of the serum was at a max. after 6 weeks of injections, at a time when antithyrotropic activity first appears. At 10 weeks the serum has a strong antithyrotropic activity, but a decreased augmentatory activity on the ovarian response. Felix Saunders

Direct gynecogenic and indirect estrogenic action of testosterone propionate in female rats. R. L. Noble. *J. Endocrinology* **1**, 184–200(1939).—Testosterone propionate in daily doses of 2 mg. for 3–4 weeks produces a stimulation of the mammary glands, a diestrus condition of the vaginal smears and mummification of the vaginal epithelium in ovariectomized adult female rats. Progesterone did not produce any consistent effect in hypophysectomized adult or immature rats, and its administration simultaneously with testosterone propionate did not modify qualitatively the effect of the latter in immature hypophysectomized animals. Felix Saunders

Recovery of injected estrogenic substances from rabbit urine. S. W. Stroud. *J. Endocrinology* **1**, 201–7(1939). —A technique for the extn. of synthetic estrogens from rabbit urine is described. The recoveries found were: for 4,4′-dihydroxy-γ,δ-diphenylhexane 21.3%, for 4,4′-dihydroxy-γ,δ-diphenyl-β,δ-hexadiene 7.2%, for 4,4′-dihydroxy-α,β-diethylstilbene 25.2 and 16.8% and for estrone 1.5%. A nonketonic phenolic metabolic product of estrone, probably β-estradiol, was isolated from the urine of rabbits receiving large injections of estrone. Felix Saunders

Effects of synthetic estrogens and carcinogens when administered to rats by subcutaneous implantation of crystals or tablets. R. L. Noble. *J. Endocrinology* **1**, 216–29(1939).—Changes are observed only after the implantation of substances which possess estrogenic activity, and are characterized in adult animals by an atrophy of the gonads with assocd. secondary effects, a reduction or cessation of body growth, and an increase in wt. of the adrenals and pituitary gland. The injection of pregnancy urine ext. into female rats treated 3 weeks by estrogen crystals caused an ovarian response similar to that seen in the intact immature rat. The rate of absorption of triphenylethylene, 4,4′-dihydroxy-β,δ-diphenyl-β,δ-hexadiene and 4,4′-dihydroxy-α,β-diethylstilbene from implanted tablets was detd. Felix Saunders

The role of hemoglobin in intermediary heat exchange. Ernst Simonson. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 323–5(1937)(in German). Walter H. Seegers

Regulatory function of the lung in intermediary metabolism. E. Simonson, E. L. Libkind, A. Ph. Naiman and A. V. Sokolov. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 326–8(1937)(in German). Walter H. Seegers

Morphology of liver function. III. So-called round cell filtration in Glisson's capsules. Syozo Oda. *J. Chosen Med. Assoc.* **29**, 1966–87(German abstr. 127–8)(1939); cf. *C. A.* **34**, 5037.—Morphological examn. of 130 human livers. S. Tashiro

The effect of noxious agents on creatine, creatinine, chloride and water excretion. J. S. L. Browne, S. Karady and H. Selye. *J. Physiol.* **97**, 1–7(1939); cf. *C. A.* **32**, 7163².—The nonadapted animal, just as the animal completely exhausted by continuous exposure, responds to damaging agents such as cold, excessive muscular exercise or toxic doses of formaldehyde with a decrease in the excretion of H_2O and Cl in the urine and with a marked increase in the urinary elimination of creatine. The animal optimally adapted to these stimuli on the other hand shows a rise in the excretion of H_2O and Cl toward or slightly above the normal level and a decrease of creatine and creatinine elimination below this level. The expts. confirm the conception that during adaptation the organism responds in a characteristic manner, and that the symptoms and signs of this response are detd. mainly by the intensity of the stimulus and the degree of adaptation which the organism has acquired to this stimulus. E. D. Walter

The occurrence of ovulation in the rabbit as a result of stimulation of the central nervous system by drugs. F. H. A. Marshall, E. B. Verney and Marthe Vogt. *J. Physiol.* **97**, 128–32(1939).—Picrotoxin in a dose of 0.9–1.1 mg./kg. was injected intravenously into rabbits in heat. Follicle growth, development of batches of cystic and hemorrhagic follicles, or ovulation ensued in a large no. of animals so treated. No ovarian responses were obtained to the injection of a series of other substances, most of which were stimulants of the central nervous system. E. D. Walter

Myosin and adenosinetriphosphatase. V. A. Engel'hardt and M. N. Lyubimova. *Nature* **144**, 668–9(1939). —The primary energy-yielding reaction in muscle, the hydrolysis of adenosine triphosphate, seems to be assocd. with the protein forming the anisotropic contractile part of muscle fiber. E. D. Walter

Acetylphosphate and pyruvate oxidation. S. Ochoa, R. A. Peters and L. A. Stocken. *Nature* **144**, 750–1 (1939); cf. *C. A.* **33**, 7370⁶.—Acetylcholine is neither an intermediate in the oxidation of pyruvic acid by brain nor does it act significantly as a donator of phosphate to adenylic acid in muscle ext. E. D. Walter

Oxidation of methyl esters of monocarboxylic fatty acids by normal and neoplastic tissue. E. Ciaranfi. *Nature* **144**, 751(1939).—Esters of fat acids increase the O consumption of normal tissue slices much more than the fatty acids themselves. Only the fat acid component of the esters is consumed. Neoplastic tissues do not oxidize the free fat acids but actively oxidize their esters. E. D. Walter

Localization of electrolytes in muscle. E. J. Conway, F. Kane, P. Boyle and H. O Reilly. *Nature* **144**, 752–3 (1939). E. D. Walter

Sex and Internal Secretions. 2nd ed. Edited by **Edgar Allen, Charles H. Danforth and Edward A. Doisy.** London: Bailliere, Tindall & Cox. 1346 pp. 54s. net.

G —PATHOLOGY

The investigation of "falling disease" of cattle in the southwest. H. W. Bennetts and H. T. B. Hall. *J. Dept. Agr. W. Australia* **16**, 156–60(1939).—Preliminary results indicate that stock in the "falling disease" area are affected with a deficiency of Cu and other minerals and this may in some ways be assocd. with the disease. J. R. Adams

Blood plasma bromide levels in bromoderma. Lester W. Kimberly. *J. Investigative Dermatol.* **2**, 331–42(1939).—There is no direct correlation between the blood plasma bromide level and the occurrence of bromoderma. The value of giving NaCl to patients with bromism is clearly shown. The tendency of bromide to replace chloride in the plasma or vice versa is confirmed. P. D. Adams

Modifications of the respiratory function of the blood during experimental pulmonary edema. I. Variations in the oxygen-saturation curve and in the progress of oxygenation and reduction of the arterial blood. D. Cordier and J. Français. *Ann. physiol. physiochim. biol.* **15**, 339–52(1939); cf. *C. A.* **33**, 1809[5], 5178[8].—The O_2-satn. curve of the blood of an animal succumbing to pulmonary edema caused by $COCl_2$ is much lower than that of normal blood. The O_2-satn. curve of an animal dying of pulmonary edema is always lower than that of normal blood to which has been added the same amt. of ether-sol. acids. The blood in $COCl_2$ poisoning has a lower affinity for O_2 than that of an animal dead from progressive anoxia. In pulmonary edema the blood is oxygenated more slowly and reduced more rapidly than normal blood. The acidification of the blood by the fixed acids in pulmonary edema cannot explain entirely the modifications of the respiratory function of the blood. The pulmonary edema caused by $COCl_2$ creates in the organism an anoxia, 3 forms of which are now evident: anoxic anoxia from lesions of the respiratory app., stagnant anoxia due to slowing of the circulation and anemic anoxia caused by the diminution of the affinity of the red cells for O_2. Ruth Berggren

The effect of vitamin C on the production of antibodies. Yosihiko Muturo. *Oriental J. Diseases Infants* **25**, 32(1939)(in English). Successive intravenous injections of typhoid vaccine and vitamin C into rabbits produced a rapid, marked and prolonged increase in the agglutination value, hemolysin value and precipitin content. In adult rabbits the normal agglutination value, hemolysin value and opsonin index increased after one intravenous injection of 40–100 mg. vitamin C/kg. body wt. but decreased after an injection of 150 mg. In normal immature rabbits the hemolysin value increased after a dose of 20 mg. vitamin C but decreased after one of 50 mg. One injection of vitamin C into a mouse increased its resistance to infection with living typhoid bacilli and prolonged its life, but injection of a large amt. (amt. not stated) seemed to decrease its resistance Ruth Berggren

Production of tumors of the spleen in rabbits by means of injections of thorotrast. C. J. van Merveemee and P. A. ten Thije. *Nederland. Tijdschr. Geneeskunde* **83**, IV, 5622–31(1939).—The injection of 3 to 4 cc. of thorotrast per kg. kills rabbits in 8 to 10 hrs. After the injection of repeated smaller doses the authors observed a development of tumors of the spleen with metastases. R. Beutner

Experimental actinomycosis. Syuzi Hassegawa, Tameziro Nakamoto, Yosio Miyasaki, Tomoyuki Arimiti and Masatoyo Akiyosi. *Japan J. Med. Sci. V. Path.* **3**, 27–83(1938).—Human actinomycosis is produced by aerobic and anaerobic varieties, infections from the latter being most usual. All species of this fungus are feebly pathogenic for dogs and other exptl animals. The course of the lesion is usually altered by mixed infection, its degree depending on the grade of mixed infection and the types of organism involved. Lucien Y. Dyrenforth

The significance of the presence of calcium bilirubin pigment and cholesterol crystals in the feces. Fred Boerner, Thos. A. Johnson and Marion Gianniny. *Am. J. Digestive Diseases Nutrition* **6**, 466–7(1939).—Of 2003 stools examd. 67 contained Ca bilirubinate, cholesterol crystals or both. The relation between Ca bilirubin pigment in the stool and cholelithiasis is discussed. E. E.

The comparative value of serial hippuric acid excretion, total cholesterol, cholesterol ester and phospholipide tests in diseases of the liver. I. Results of the tests. Franklin W. White, Emmanuel Deutsch and Stephen Maddock. *Am. J. Digestive Diseases Nutrition* **6**, 603–10(1939).—Studies on 64 cases are recorded. Edward Eagle

The effect of pregnancy and of antuitrin-S on cinchophen ulcers in dogs. A. A. Farbman, David J. Sandweiss and Harry C. Saltzstein. *Am. J. Digestive Diseases Nutrition* **6**, 702–3(1939).—Pregnancy and injections of antuitrin-S had only slight effect on cinchophen ulcers in dogs. Edward Eagle

New knowledge of fluorine in relation to dental caries. Gerald J. Cox. *J. Am. Water Works Assoc.* **31**, 1926–30(1939).—Investigations have shown that F in water supplies causes endemic mottled enamel, and also recently it has been demonstrated that the element most responsible for increased caries-resistance is F. It has also been noted that mottled enamel does not increase caries. D. K. F.

Variations in the polypeptide contents of blood and spinal fluid of typhoid and anthrax patients. A. Slatineanu, I. Balteanu, I. Potop and M. Franche. *Compt. rend. soc. biol.* **132**, 287–90(1939); cf. *C. A.* **33**, 1384[6], 1791[2].—Small increases occurred. L. E. Gilson

Failure of wheat-germ oil to produce neoplasms. R. Auchincloss and C. D. Haagensen. *Proc. Soc. Exptl. Biol. Med.* **42**, 703–5(1939). L. E. Gilson

Histology of the thyroid in exophthalmic goiters and hyperthyroidism. C. A. Hellwig. *Arch. Path.* **28**, 870–903(1939).—A general review with 107 references. Harriet F. Holmes

Hyperinsulinism and surgery. E. Åkerberg. *Acta Chir. Scand.* **83**, 104–22(1939).—A patient is described with persistent and very severe hypoglucemia. On operation an islet adenoma was removed, whereupon the blood sugar rapidly increased without the administration of glucose or of adrenaline. S. Morgulis

Further observations on the value of heated elementary body suspensions in immunization against experimental influenza. R. W. Fairbrother and A. E. Martin. *Arch. ges. Virusforsch.* **1**, 114–19(1939)(in English); cf. *C. A.* **32**, 2609[9].—Further evidence has been obtained that elementary body suspensions heated at 57° for 30 min. and treated with 0.5% phenol effect satisfactory immunization against exptl. influenza in mice, lasting more than 8 weeks. These suspensions are noninfective, bacteriologically sterile, and stable for at least 6 months at 0–4°. They are therefore suitable for experimentation on human subjects. J. Pinchack

The metabolism of acetone bodies in acute pancreatic disturbance. I. Acetone bodies in the blood and urine in acute pancreatic disturbance of rabbits. Akira Sirakura. *Japan. J. Gastroenterol.* **11**, 49–57(1939).—Ligation of the pancreatic ducts of rabbits results in a low concn. of total acetone bodies in the blood while that in the urine was slightly higher. The abs. amt. of acetone bodies excreted in the urine in 24 hrs. was diminished. These changes disappeared on the 2nd–4th days after the operation. Introduction of olive oil or pancreatin into the pancreatic duct gives the same results as l[illegible]
The changes disappeared on the 4th–10th days after the
[illegible] forming acetone
c duct. *Ibid.* 58–
[illegible] butyrate were injected into rabbits with ligated pancreatic duct and the managing function and the forming function for acetone bodies studied. The function managing acetone bodies was slightly decreased 1 day after the operation, nearly recovered after 3 days, promoted after 5–7 days, and came back to normal again. The function producing acetone bodies was lowered 1 day after the operation with promotion on the reverse after 5 days and normal after 10 days.

III. **Function of disposing and forming acetone bodies in rabbits with acute pancreatic necrosis.** *Ibid.* 64–8.—Results of this paper are similar to those of paper II. Benjamin Prescott

Cerebral metabolism during fever. Harold E. Himwich, Karl M. Bowman, W. Goldfarb and Joseph F. Fazekas. *Science* **90**, 398(1939).—The brain metabolism of patients with general paresis was studied before and during fever produced by injections of typhoid vaccine or inductotherm therapy. Samples of arterial blood and of the return flow of the brain obtained from the internal jugular vein were analyzed for O, CO_2, glucose and lactic acid. In every instance an increase of cerebral metabolism during fever was indicated. Felix Saunders

Investigations in atypical toxicoses of pregnancy. H. Albers. *Arch. Gynäkol.* **168**, 754–74(1939).—Seven cases were reported, 4 of which, on the basis of chem. analysis, were proved to be toxicoses of pregnancy. In the first case, a fatal uremia developed during childbed with the nonprotein N rising from 30 mg. % before delivery to 122 mg. % shortly before death and the serum NaCl correspondingly dropping from 715 to 430 mg. %. In the absence of glomerular damage at autopsy, the hypochloremia was interpreted as secondary to an increased protein catabolism, possibly overproduction of guanidine. In case 2, a severe hyperemesis gravidarum was assocd. with a primary hypochloremia (about 400 mg. % serum NaCl) and corresponding rise in nonprotein N to 120 mg. %. Serum chemistry in cases of chorea gravidarum and eclamptic apoplexy is presented in a table, together with av. figures of normal standards. H. P. G. Seckel

Blood iodine content of childhood. W. Schwenk. *Monatsschr. Kinderheilk.* **79**, 349–61(1939).—In 50 normal children av. figures of blood I were according to age groups: up to 1 year 10.25, 2 to 6 years 11.23, 7 to 9 years 12.59, 10 to 11 years 12.64, 12 to 14 years 11.58 γ % (mean 11.67 γ %). The following figures were found in various morbid conditions:

Condition	No of cases	Age in years	Average blood I, γ, %	Effect of I treatment
Congenital struma	2	newborn	9.3	Increased
Nontoxic struma	1	7	7.3	Increased
Nontoxic struma	9	11–15	9.5	Increased
Myxedema	3	10; 6; 7	6.0	None
Cretinism	3	7, 2, 4	6.4	None
Mongolism	2	1, 7	6.9	None
Obesity (girls)	3	12–14	10.4	Increased
Rickets	7	½–2	10.3	Not given

With the findings in rickets, earlier observations to the contrary by Nitschke (cf. *C. A.* **28**, 2037[4]) were disproved for the third time. H. P. G. Seckel

The role of histamine in allergy reactions. I. I. Schimanko. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 381–4(1937) (in German). Walter H. Seegers

Influence of specific treatment on the state of the hemato-encephalic barrier from the viewpoint of its permeability to bromine in infants afflicted with congenital syphilis. M. Silberstein and E. Birguer. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 385–8(1937)(in French).—Blood and cerebrospinal fluid were drawn simultaneously. The quantity of Br in the serum of infants with congenital syphilis is less than that of healthy infants. With specific treatment serum Br increases considerably. In general, the ratio of Br in the cerebrospinal fluid to Br in serum is near 63 in diseased individuals and drops to about 32 under treatment. Walter H. Seegers

Release of autonomic humoral substances in hypoglucemic cats and monkeys. M. B. Bender and S. Siegal. *Am. J. Physiol.* **128**, 324–31(1940).—Adrenergic and cholinergic humoral effects take place in response to hypoglucemia, the adrenergic phenomena predominating in the cat. Much slighter autonomic effects are demonstrable in the monkey. This may be explicable on the basis of relative insensitivity of the indicators rather than as significant of a fundamental difference in autonomic responses. E. D. Walter

Trans-amination of *l*- and *d*-amino acids in normal muscle and in malignant tumors. A. E. Braunshtein and R. M. Azarkh. *Nature* **144**, 669–70(1939); cf. *C. A.* **33**, 5015[2].—Expts. show that trans-amination of *d*- and *l*-amino acids is either not effected at all by minced tissue from various malignant tissues or at a much lower degree than it is by normal tissues. E. D. Walter

The partition of serum calcium in domestic animals—some pathological cases. J. Duckworth and W. Godden *Vet. J.* **95**, 380–92(1939).—Ca^{++}, ultrafiltrable Ca (in phosphate-bicarbonate complex), nonultrafiltrable Ca (in an unknown complex form), protein-bound Ca and total Ca were detd. in the blood of 13 farm animals including cows with hoven, retained placenta, stomach staggers and acetonemia, calves with convulsions, a horse with grass sickness, a sheep with dropsy, 2 sheep with tetany and 3 sheep with rickets. The tetany cases showed low values for Ca^{++} and extremely low values for protein-bound Ca. Rapid reduction of nonultrafiltrable Ca complex at time of greatest severity of the symptoms was characteristic of the cases of rickets. C. W. Whittaker

Food poisoning due to staphylococci with special reference to staphylococcus agglutination by normal horse serum (Slocum, Linden) **12**.

H—PHARMACOLOGY

CARL F. SCHMIDT

Histaminase in the treatment of urticaria and atopic dermatitis. Carl W. Laymon and Harry Cumming. *J. Investigative Dermatol.* **2**, 301–12(1939).—A preliminary report. Philip D. Adams

Influence of salyrgan upon the blood volume. E. Lopez Cardozo. *Nederland. Tijdschr. Geneeskunde* **83**, IV, 5528–32(1939).—In decompensation, the administration of salyrgan causes a 20 to 30% diminution of the blood vol., which is far above the normal level in that condition. This diminution results from a decrease of both the plasma and the red blood cell vol. The plasma becomes concd. during diuresis; the red cells somehow disappear. R. Beutner

Anesthesia. The conquest of pain. Edward Podolsky. *Am. Professional Pharmacist* **5**, 629–31, 638, 695–7(1939). A historical discussion of general anesthetics and procedures. H. M. Burlage

The irritant action of the chloroximes. Mario Milone. *Ann. chim. applicata* **29**, 360–6(1939).—The reactions of chloroisonitrosoacetone (I) and of chloroisonitrosoacetophenone (II) on the skin were investigated in rats. The oximes of I and II were also prepd. I and its oxime have an irritant action, while II and its oxime have not. It is known that I reacts much more readily with proteins and lipides than II, which accounts for this difference in irritant action on the skin. A. W. Contieri

Some recent applications of caryoclastic poisons. A. P. Dustin. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 227–30(1939). E. Curzon

Effect of diphenols on the small intestine. S. Zylbersztac. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 240(1939). E. Curzon

Action of colchicine on nervous cicatrization. R. Delcourt. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 241(1939). E. Curzon

Intubation studies of the human small intestine. XVII. The effect of atropine and belladonna on the motor activity of the small intestine and colon. Kendall A. Elsom and J. L. Drossner. *Am. J. Digestive Diseases Nutrition* **6**, 589–93(1939).—The effects of atropine sulfate and tincture of belladonna (administered to normal subjects and patients with gastrointestinal disease) on the small intestine and colon were studied by means of intestinal intubation combined with fluoroscopy. Therapeutic doses produced a marked decrease in tone and in peristaltic activity and a less striking effect on rhythmical contractions. **XVIII. The effect of pitressin and of amphetamine (benzedrine) sulfate on the motor activity of the small intestine and colon.** Kendall A. Elsom, Paul M. Glenn and J. L. Drossner. *Ibid.* 593–7.—Pitressin produced an increase in motor activity of the intestinal tract,

usually with increased tone and peristaltic activity. The effects of pitressin were more intense in the more distal portions of the tract. Benzedrine sulfate exerted a sympathomimetic effect on the small bowel and colon, with decreased tone and peristaltic activity. Edward Eagle

The oral administration of citrated blood in man. I. The effects on the blood urea nitrogen. Leon Schiff, Richard J. Stevens, Sander Goodman, Ellen Garber and Anna Lublin. *Am. J. Digestive Diseases Nutrition* **6**, 597-601(1939).—Intragastric or intrajejunal administration of citrated human blood in single doses of 250 to 1000 cc. is followed by a significant rise in the blood urea N, this rise being proportional to the amt. of blood administered, and dependent on the portion of the intestinal tract into which the blood is placed. The rise usually returns to normal within 48 hrs. and is apparently dependent on the digestion and absorption of the blood. Edward Eagle 2

The effect upon gastric secretion of introducing dilute hydrochloric acid into the duodenum. R. E. Stevens, H. L. Segal and W. J. Merle Scott. *Am. J. Digestive Diseases Nutrition* **6**, 706-11(1939).—HCl in 0.4% soln., when introduced into the duodenum of normal subjects or of duodenal ulcer patients, had no const., significant effect on gastric secretory curve. Edward Eagle 3

The use of homatropine-benzedrine cycloplegia. Lyle S. Powell. *Am. J. Ophthalmol.* **22**, 956-9(1939).—Two one-drop instillations in the conjunctival sac of 2% aq. homatropine-HBr soln. followed in 5 min. by 2 instillations of 1% benzedrine sulfate ophthalmic soln. produced complete practical cycloplegia in 60 min. in patients 16 to 31 yrs. old. Beginning recovery occurred in 4 hrs. Eserine salicylate (1 or 0.5% soln. buffered to be isotonic with tears) overcomes homatropine-benzedrine cycloplegia promptly and restores the power of accommodation within $\frac{1}{2}$ hr. Edward Eagle 4

Prophylactic foreign protein therapy in cataract extraction. C. A. Noe. *Am. J. Ophthalmol.* **22**, 1014-17(1939).—Prophylactic intravenous administration of typhoid-H antigen lessens the inflammatory reaction after cataract extn. and gives rise to both "O" and "H" antibodies in the blood. There is no definite relationship between blood-antibody titer and postoperative reaction. Edward Eagle 5

A study of the fate in the organism of some chlorinated hydrocarbons. H. M. Barrett, J. G. Cunningham and J. H. Johnston. *J. Ind. Hyg. Toxicol.* **21**, 479-90(1939).—Between 5 and 8% of the trichloroethylene absorbed by dogs after inhalation anesthesia is excreted in the urine as trichloroacetic acid. No such conversion was noted after the administration of CCl_4, 1,1,2-trichloroethane and $CHCl_3$. *S*-tetrachloroethane is one of the most toxic of the chlorinated hydrocarbons. A. L. Elder 6

Pharmacognosy of Chelidonium majus L. IV. Heinrich Cappenberg and Heinz Harms. *Deut. Apoth.-Ztg.* **54**, 40(1939).—This study is based essentially on the alkaloidal salts. Thirty-four references. W. O. E. 7

Poisoning by radioactive substances. Gyula Balázs. *Orvosi Hetilap* **83**, 893-7(1939).—Cases described in the literature are summarized. Small doses of radioactive substances seem to have a curative power; larger amts. usually cause severe injury within the cells. S. S. de F. 8

Production of anemia in white mice by sulfanilamide, sulfapyridine and diaminodiphenylsulfone. Arthur P. Richardson. *J. Pharmacol.* **67**, 429-36(1939).—An anemia assocd. with reticulocytosis was produced by feeding mice diets contg. the drugs. On the basis of minimal effective blood concn. which is necessary to produce a significant effect on the red cells, sulfapyridine is about half as toxic as sulfanilamide and diaminodiphenylsulfone about twice as toxic as sulfanilamide. L. E. Gilson 9

Mechanism of insulin convulsions. III. Effects of varying partial pressures of atmospheric gases after adrenalectomy. Irvine McQuarrie, M. R. Ziegler, W. E. Stone, O. H. Wangensteen and C. Dennis. *Proc. Soc. Exptl. Biol. Med.* **42**, 513-14(1939); cf. *C. A.* **33**, 7385[6].—Breathing a mixt. of 5% O_2 and 95% N_2 causes hypoglucemia in adrenalectomized dogs without insulin, and hypercemia in normal dogs. Insulin convulsions are prevented by anoxia of this degree even when the blood sugar falls to 9-14 mg.%. Breathing a mixt. of 15% CO_2, 20% O_2 and 65% N_2 also tends to prevent insulin convulsions. L. E. Gilson 10

Effect of sulfapyridine on immune responses to pneumococcal infection. Joseph C. Edwards, Theodor E. Kircher, Jr., and Lawrence D. Thompson. *Proc. Soc. Exptl. Biol. Med.* **42**, 539-41(1939).—The immune responses that occur naturally in man in untreated pneumonia, studied by detg. type-specific and species-specific agglutinins and by the dermal reactivity to type-specific polysaccharides, are apparently unaltered by treatment with sulfapyridine. There seems to be no relation of the heterophile-antibody titer to the clinical course of pneumococcal pneumonia or its immune responses following sulfapyridine therapy. L. E. Gilson 11

Toxicity of the *o*-, *m*- and *p*-isomers of sulfanilamide. Edwin P. Laug and Herman J. Morris. *Proc. Soc. Exptl. Biol. Med.* **42**, 541-3(1939).—When given orally to mice the median lethal doses of the isomers are: *o*- 3.84, *m*- 12.45 and *p*- 4.61 g./kg. There is no correlation between soly. and toxicity or between toxicity and therapeutic efficiency as reported by others. L. E. Gilson 12

The local anticonvulsive action of calcium salts. R. Beutner. *Proc. Soc. Exptl. Biol. Med.* **42**, 547-9(1939).—In guinea pigs the intramuscular injection of 100-200 mg./kg. of procaine-HCl caused clonic and tonic convulsions. Mixing $CaCl_2$ with the procaine-HCl greatly decreased the incidence of convulsions. Other Ca salts acted like $CaCl_2$, except Ca gluconate which does not ionize. $MgCl_2$ counteracts the action of $CaCl_2$, probably by altering membrane permeability, and in the absence of Ca increases the convulsive action of procaine. L. E. Gilson 13

Toxicity of acid-soluble typhoid toxin for laboratory animals. E. W. Dennis. *Proc. Soc. Exptl. Biol. Med.* **42**, 553-4(1939).—The fraction contg. the somatic antigen complex of the typhoid bacillus is highly toxic. The macroscopic changes produced are those attributed to the endotoxin. The effect is primarily on the blood vessels, resulting in degenerative changes in the tissues supplied. A monocytic response is not a component of the tissue response to the toxin. L. E. Gilson 14

Effect of sulfapyridine on Brucella abortus in vitro and in vivo. E. E. Hamann and I. F. Huddleson. *Proc. Soc. Exptl. Biol. Med.* **42**, 555-6(1939).—A 1:10,000 concn. of sulfapyridine has some bacteriostatic action on *Brucella abortus in vitro*, but oral administration in large doses to infected guinea pigs has little or no effect on the course of the infection. L. E. Gilson 15

Action of tincture of iodine when injected into the pericardial sac. J. A. Bone and J. W. Elam. *Proc. Soc. Exptl. Biol. Med.* **42**, 563-4(1939).—Preliminary. L. E. Gilson 16

Inhibition by cortin of the blood-sugar changes caused by adrenaline and insulin. Hans Selye and Christiane Dosne. *Proc. Soc. Exptl. Biol. Med.* **42**, 580-3(1939); cf. *C. A.* **33**, 7331[3].—In fasted adult male rats both the hypoglucemia caused by insulin and the hyperglucemia provoked by adrenaline can be largely, but not completely, suppressed by cortin. It appears that cortin exerts a stabilizing effect on blood sugar much like that obtained with certain hypophysis exts. by Neufeld and Collip (*C. A.* **33**, 1795[9]). L. E. Gilson 17

Rate of elimination of nicotine by the rabbit. J. H. Weatherby. *Proc. Soc. Exptl. Biol. Med.* **42**, 593-6(1939).—When repeatedly injected in small doses the rate of elimination is proportional, within certain limits, to the rate of administration. When the optimum rate of injection is passed the rate of elimination decreases to less than the max., i. e., the elimination curve bends downward. L. E. Gilson 18

Effect of thiamine chloride on Eimeria nieschulzi infection of the rat. Elery R. Becker. *Proc. Soc. Exptl. Biol. Med.* **42**, 597-8(1939); cf. *C. A.* **32**, 5037[6], 7079[8].—Large doses of thiamine chloride retarded the development of the coccidium in its rat host. L. E. Gilson 19

Diabetes in rats and its alleviation with sodium chloride. James M. Orten and Henry B. Devlin. *Proc. Soc. Exptl.*

Biol. Med. **42**, 632–4(1939).—About 50% of adult rats of the "Yale" strain show a diabetic tendency (low glucose tolerance). The injection of NaCl with the glucose results in a normal tolerance to glucose, both in intact rats with the diabetic trait and in partially pancreatectomized rats. L. E. Gilson

Further observations of phenothiazine in experimental trichinosis. James B. McNaught, Rodney R. Beard and Floyd DeEds. *Proc. Soc. Exptl. Biol. Med.* **42**, 645 8 (1939); cf. *C. A.* **33**, 8300².—Contrary to the previous report phenothiazine is of no value in the treatment of trichinosis infection. L. E. Gilson

The prevention of carotene absorption by liquid petrolatum. Arthur C. Curtis and Robert S. Ballmer. *J. Am. Med. Assoc.* **113**, 1785–8(1939).—Liquid petrolatum interfered with absorption of carotene from food. Petrolatum satd. with carotene at 37° (0.28%) did not influence carotene absorption. F. P. Griffiths

Nonsurgical aspects of the kidney stone problem. Fuller Albright, Hirsh W. Sulkowitch and Richard Chute. *J. Am. Med. Assoc.* **113**, 2049–53(1939).—A soln. of Na citrate-citric acid at pH 4.0 is effective in dissolving $Ca_3(PO_4)_2$ stones *in vitro* and *in vivo*. The soln. combines the effect of acids on phosphates with a complex ion effect to reduce the Ca-ion concn. Na hexametaphosphate, $Na_3(NaPO_3)_6$, solns. have been suggested as being more effective than citrate-citric acid. F. P. Griffiths

The reaction of the coronary vessels to drugs and other substances. Louis N. Katz and Erna Lindner. *J. Am. Med. Assoc.* **113**, 2116–19(1939). The actions of a variety of drugs, salts and bloods of foreign species on the tone of the coronary vessels of the dogs are reported. Coronary vasodilator substances are adrenaline, acetylcholine derivs., $CaCl_2$, NaCl, $NaNO_2$, nitroglycerin, histamine, caffeine, aminophylline and other xanthines and diffusible substances liberated in myocardial ischemia. Vasoconstrictor substances are ergotamine, piperidinomethylbenzodioxane, pitressin, atropine sulfate and substance in defibrinated foreign species blood. KCl acts as a vasoconstrictor when greater than 1.5 normal blood concn. and as a vasodilator when less than that concn. F. P. G.

Respiratory alkalosis during anesthesia. An experimental study in man. M. H. Seevers, R. T. Stormont, H. K. Hathaway and R. M. Waters. *J. Am. Med. Assoc.* 113, 2131–6(1939).—Eleven patients were manually hyperventilated for periods of 11 to 21 min. during anesthesia with different agents. A marked respiratory alkalosis developed, the av. being 0.31 pH unit above anesthesia level and 0.25 unit above normal plasma pH. The CO_2 level in the blood was reduced 21 mm. below the mean anesthesia level and 31 mm. below the mean normal level. Systolic and diastolic arterial pressures were reduced from the elevated levels of anesthesia 25 and 10 mm., resp. The initial arterial pressures were reëstablished rapidly when hyperventilation was discontinued and no adverse effects on the circulation or general condition of the patients followed hyperventilation. Arterial hypotension due to rapid removal of CO_2 is not surgical shock since the hypotension is not progressive, recovery of arterial pressure occurs even during continued ventilation, and recovery is immediate when hyperventilation is discontinued. F. P. Griffiths

Pharmacology of strontium. V. Direct action on bulbar and cortical centers. A. Boriani. *Arch. farmacol. sper.* **68**, 105–22(1939); cf. *C. A.* **33**, 8301⁸; **34**, 168².
Helen Lee Gruehl

Effect of potassium iodide on bone and cartilage in thyroidectomized immature guinea pigs. M. Silberberg and R. Silberberg. *Arch. Path.* **28**, 846–50(1939); cf. *C. A.* **33**, 6424⁷·⁸.—In immature male guinea pigs in which the thyroid glands were completely or almost completely removed KI caused proliferation of the euhyaline cartilage as it does in nonthyroidectomized animals. In this respect KI acts on the growth of the cartilage without the mediation of the thyroid gland. However, the increase in the no. of hypertrophic cartilage cells, the decrease of ossification, and the stimulation of resorption of bone which occurred when the thyroid gland was intact were lacking when the thyroid gland had been removed previous to the administration of KI. These processes, which under the influence of KI are seen only in guinea pigs with intact thyroid glands, are held to depend on certain functions of the thyroid gland. Harriet F. Holmes

The protein fractions in blood and spinal fluid after poisoning of the nervous system with carbon monoxide. V. A. Bakhtiyarov. *Klin. Med.* (U. S. S. R.) **16**, 726–9 (1938).—Chronic CO poisoning decreases blood and spinal fluid albumin, increases blood and spinal fluid globulin, and decreases the permeability of the hematoencephalic barrier. S. A. Karjala

Influence of sodium fluoride, sodium maleinate, glutamic acid and glyceraldehyde on muscular activity. A. M. Ryabinovskaya. *Compt. rend. acad. sci. U. R. S. S.* **23**, 958 61(1939)(in English).—A survey of the existing literature is followed by expts. with a nerve-prepn. muscle (sciatic-gastrocnemius) and sartorius muscle of a frog, with Ringer soln. for control. NaF in concn. of 0.02 *M* for 1 hr. produces a reduction of the amplitude and a rise of the excitability to direct stimulation; indirect excitability (via nerve) is lacking. Na maleinate (0.0025 *M*) in the presence of phosphate buffer (pH = 7.2–7.3) produces a lowering of direct excitability in both muscles and of indirect excitability in m. gastrocnemius. Na glutaminate (0.01 *M*) eliminates indirect excitability and lowers direct excitability, though to a lesser degree than NaF. Glyceraldehyde (0.02 *M*) leads to a decrease of both direct and indirect excitability. 16 references. A. H. Krappe

Alcohol and sedatives. Helmut Peter. *Deut. Z. ges. gerichtl. Med.* **31**, 113–53(1939).—Impairment of attentiveness and concn. power paralleled the limits of motor performance and blood alc. level. Phenobarbital, 0.3 g., had the same effects as alc., 1 g./kg. body wt. when the subject was tested objectively. Sedormid impaired the motor ability of one case slightly. Cibalgin was effective only after exercise. Subjective tests showed that the effects of phenobarbital and alc. can be differentiated. Together with alc. even the relatively ineffective cibalgin produced a real narcosis; pyramidone produced a sense of well-being with no improvement in motor performance. Frances Krasnow

A fatal case of accidental poisoning by chlorate of potassium, with a review of the literature. W. J. Cochrane and R. P. Smith. *Can. Med. Assoc. J.* **42**, 23–6 (1940).—A discussion of the symptoms and postmortem findings in a case of accidental poisoning from taking 30–35 g. of $KClO_3$. G. H. W. Lucas

Anuria caused by sulfapyridine therapy. E. Smith, K. A. Evelyn and J. F. Nolan. *Can. Med. Assoc. J.* **42**, 27–9(1940).—The formation of acetylsulfapyridine crystals caused a complete bilateral ureteral blockage after the administration of 42 g. sulfapyridine and 9 g. neosulfanilamide in 4 weeks. G. H. W. Lucas

The toxic effects of sulfanilamide and related compounds. E. H. Bensley. *Can. Med. Assoc. J.* **42**, 30–3 (1940).—A review. G. H. W. Lucas

Pharmacodynamics of some saponins, particularly of the saponin of Dumoria heckeli (Sapotaceae). P. Dodel, G. Dastugue and Mlle. Villedieu. *Bull. sci. pharmacol.* **46**, 401–7(1939).—Five mg. *Dumoria* saponin (I) per 100 g. animal dissolved in physiol. NaCl soln. and injected intraperitoneally in guinea pigs causes death within 2 hrs.; 7.5 mg. *Saponaria* saponin (II) causes death in 4 hrs. and 60 mg. guaiac saponin (III) in 24 hrs. The min. lethal dose by intravenous application in the rabbit is 8 mg. per kg. of I; 17 mg. of II or 150 mg. of III does not cause death. A drop in blood pressure, amounting to 30 mm. Hg in the rabbit in urethan narcosis, is produced by 0.5 mg. per kg. of I, 5 mg. of II and 150 mg. of III. The hypotensive action of I is attenuated by double vagotomy; eserine sulfate has no appreciable effect on it. The hypotensive effect is not due to acetylcholine. The imbibition observed in frog gastrocnemicus muscle when immersed in H_2O or Ringer soln. is considerably diminished and, at higher concn., reversed by the addn. of II or III. The muscle of the leech is not sensitized by I to the action of acetylcholine either in the presence or in absence of eserine.

I at a concn. of 1:10,000 causes an increase of tonus and decrease of amplitude of the beat of the heart of *Helix pomatia*. The same effect is obtained by II at 5 10,000 but not by III at 1·1000. The actions of I on the rabbit intestine are: at concn. 0.3·10,000 drop in tonus and decrease of contractions, at 1.5 10,000 increase of tonus and decrease of contractions, effects prevented by atropine. The action of II is similar; that of III is variable.
A. E. Meyer

The special contraction of partially veratrinized muscle. Kiyotune Inoue. *Japan. J. Med. Sci. III. Biophys.* **6**, 29–53(1939).—In order to obtain 2 typical veratrine contractions by 2 succeeding stimuli an interval of 4 min. is necessary to prevent a modification of the second contraction. A muscle fixed in the center and veratrinized on one side only always gives a veratrine response no matter which parts of the muscle is stimulated. This is not due to a veratrine leakage. The veratrine-effect curve was studied in various modifications of the expt. A. E. M.

Pneumonia in adults and children treated with 2-(*p*-aminobenzenesulfonamido)pyridine. A. Eldahl. *Acta Med. Scand.* **102**, 324–39(1939).—Of the 38 adults and 16 children suffering from pneumonia (types 1, 3, 4, 6 and 7, in the order of diminishing frequency) treated with 2-(*p*-aminobenzenesulfonamido)pyridine only 1.9% mortality was directly attributable to the pneumonia, 3 other patients having died from complications. The substance was administered in 0.5–1.0 g. doses every 4 hrs., adults receiving 28 and children 10 g. The children seem to have tolerated it much better than the adults. S. Morgulis

Pneumonia in adults and children treated with 2-(*p*-acetylaminobenzenesulfonamido)pyridine. A. Eldahl. *Acta Med. Scand.* **102**, 340–56(1939). Fifty-five patients both adults and children (types 1, 6, 7, 3, 19, in the order of diminishing frequency) were treated with a total of 40 and 25 g., resp., of 2-(*p*-acetylaminobenzenesulfonamido)-pyridine. The mortality was 3.6%. In two-thirds of the patients the temp. fell to normal within 48 hrs. The toxic symptoms, especially vomiting, were less common with this substance. S. Morgulis

Creatinuria in thyrotoxicosis. Knud Brøchner-Mortensen and Eggert Møller. *Acta Med. Scand.* **102**, 417–31(1939).—No proportionality was found in a large no. of patients with thyrotoxicosis between the basal metabolic rate and the creatine-creatinine excretion. Prior to I treatment an increased creatine excretion (more than 200 mg. in 24 hrs.) was found in about two-thirds of the cases, while after the treatment the creatinuria decreased in 10% of the cases. X-ray treatment had no effect on the creatinuria. Similarly, immediately after a subtotal thyroidectomy the creatinuria remained unchanged.
S. Morgulis

The action of some phenyl-substituted aliphatic amines on the perfused surviving heart. V. Larsen. *Skand. Arch. Physiol.* **82**, 288–98(1939).—Hydroxyphenylamines increase the min. vol. and frequency of the surviving heart even in dil. soln., but amines with ordinary Ph groups have practically no stimulating effect. In solns. more concd. than 1 200,000 they inhibit the min. vol. due to a change in pulse vol., the inhibition increasing with the concn.
S. Morgulis

The action of some indifferent narcotics on the acetylcholine sensitivity of the rectus muscle of the frog. Nils Emmelin. *Skand. Arch. Physiol.* **83**, 69–76(1939).—Various alcs. (Me, Et, Pr, Bu, Am) increase the action of acetylcholine on the frog rectus muscle proportionally to their no. of C atoms. Expts. with 3 isomeric Bu alcs. show that the tertiary alc. has a weak action while normal primary BuOH and isobutyl alc. have a strong action. Neither glycerol nor ethylene glycol has any effect. The sensitiveness toward acetylcholine is also increased by Me, Et, Pr esters of carbamic acid, methylurethan having the weakest and propylurethan the strongest action. Certain narcotics increase the sensitivity to acetylcholine and their effect persists even after the complete paralysis of the choline esterase by physostigmine. S. Morgulis

Citric acid metabolism in the kidneys after administration of malic acid. Johan Mårtensson. *Skand. Arch. Physiol.* **83**, 113–20(1939); cf. *C. A.* **33**, 7138.—By far the largest part of citric acid supplied to the kidney is converted, only a small portion being excreted in the urine. On the administration of malic acid, citric acid is not formed in the kidneys. *l*-Malic acid arrests or suppresses the normal breakdown of citric acid in the kidneys and at the same time brings about a large increase in the urinary excretion of citric acid. S. Morgulis

Utilization of glucose and phosphate metabolism in hind-limb preparations of cats poisoned with phlorizin. Å. Liljestrand and E. Lundsgaard. *Skand. Arch. Physiol.* **83**, 121–31(1939).—The utilization of glucose in the musculature of phlorizin-poisoned animals proceeds normally, as does also the phosphorylation process. This does not contradict the demonstrable *in vitro* inhibition of phosphorylation by phlorizin since here the concn. required is much greater than is possible in ordinary phlorizin poisoning in the living animal. A starving phlorizin-poisoned animal has a low carbohydrate tolerance owing to severe carbohydrate lack which is responsible for the diabetic glucose-tolerance curve. The authors found that the perfused liver, from well-fed phlorizin-poisoned cats, which is fat-infiltrated and practically free from glycogen, cannot form glycogen from fructose as the normal cat liver does. This is also attributed to carbohydrate lack. Phlorizin attacks selectively the kidneys interfering with reabsorption of glucose possibly through inhibition of phosphorylation. The poison tends to accumulate in the renal tubules which accounts for the toxic effect, but no such concn. is found in other tissues. The resulting diabetic condition is not due to decreased glucide combustion but is, especially in the starved animal, the result of extreme carbohydrate lack. The latter, of course, may be responsible for a diminished insulin output. Under similar conditions the glucose tolerance will be of increasing severity in the following order: rabbit, cat, dog. The tolerance will be decreased most seriously by a fat diet or by inanition, whereas with ample protein or carbohydrate there may be no reduction in tolerance. S. Morgulis

Cardiometric study of the cardiotonic properties of several sympathomimetic amines. Robert Charlier. *Arch. maladies coeur vaisseaux* **32**, 690–710(1939).—The circulatory analeptics (*p*-hydroxyphenyl)(methylamino)-ethanol (sympathol) (I), (*m*-hydroxyphenyl)(methylamino)ethanol(neosynephrine) (II), epinephrine (levorenine) (III), α-methylphenethylamine (benzedrine) (IV), α,*N*-dimethyltyramine (veritol) (V), *p*-hydroxyephedrine (suprifen) (VI), ephedrine (VII), a 1 4 mixt. of hydroxyephedrine and a lobeline-like compd. (ieoral) (VIII), and a mixt. of III and a compd. related to *N*,*N*-diethylnicotinamide (cardiovasculare) (IX), have been tested for their effect on myocardial contraction in anesthetized, vagotomized dogs. I, II and III are good analeptics because they have a vascular and myocardial effect, but II and III produce too sudden a hypertension for some myocardial conditions; I and II have a more prolonged effect than III. IV and V have a comparable cardiovascular action, but their hypertensive and cardiotonic actions are less pronounced than those of the ethanol derivs. Furthermore, these actions are reversed with repetition of injections. VI, VII and IX seem to be valuable cardiotonics since their increase of myocardial contraction appears to be independent of the simultaneous increase in arterial pressure. Small doses of VIII have a favorable effect on the myocardium, but doses which raise the pressure are toxic. The results are compared with those reported in the literature. 117 references.
J. Pinchack

Neuro-histopathology of metrazole and insulin shock therapy. Experimental study in the cat. N. W. Winkelman and Matthew T. Moore. *Trans. Am. Neurol. Assoc.* 1939, 214–16.—Insulin (I) caused severe damage of the neurones, while metrazole (II) produced practically no morphologically demonstrable change in the central nervous system of the cat. These results may indicate the need for greater caution in the use of I in human subjects; II may be considered the safer drug. J. Pinchack

The toxicity of various iodine solutions. A. L. Berman and A. C. Ivy. *J. Lab. Clin. Med.* **25**, 113–20(1939).—

The relative toxicity of various solns. used clinically in the treatment of thyrotoxicosis was investigated by these procedures: (1) the depression of the blood pressure observed in ether-anesthetized dogs when various I solns. equiv. in I content were injected intravenously during a period of 10 to 15 sec.; (2) the least amt. of Amend's and Lugol's soln. that would induce vomiting when injected intravenously in unanesthetized dogs who had been given a meal; (3) the blood I curves of 8 normal human subjects and 4 dogs were detd. after ingestion of I equiv. amts. of these 2 solns.; (4) the rate of absorption was detd. by the time of occurrence of the peaks in the blood I curves of human subjects and by the time of appearance of I in the saliva after 50 mg. of I in solns. had been given by Rehfuss' stomach tube; (5) the uptake of I by the thyroid in dogs anesthetized with nembutal following injection of I solns.; and (6) the toleration by I-sensitive subjects of the various solns. The degree of toxicity is related to the presences of the Na or K cation in the soln., to the presence of a buffering agent such as protein to neutralize free I if the latter is present and possibly to the amt. of protein iodide formed during absorption of orally administered I. Amend's soln. and NaI are less toxic when given intravenously, are less irritating to the stomach when taken orally, and are better tolerated than Lugol's soln. in I equiv. doses. Amend's soln. should be as effective as Lugol's soln. in the treatment of hyperthyroidism when given in I equiv. doses as the I in both solns. were utilized to approx. the same extent by thyroid tissue. The irritating effects of Lugol's soln. are greatly reduced if this soln. is administered in milk. Howard W. Robinson

The relationship of the insulin hypoglucemic reaction to shock. Warren C. Corwin. *J. Lab. Clin. Med.* 25, 769–74(1939).—Hypoglucemic manifestations ("insulin shock") were produced in dogs and rabbits by the injections of fatal and nonfatal doses of insulin. Detns. of the hemoglobin content and the no. and vol. of erythrocytes in the blood indicate that hemoconcn. does not occur incident to such hypoglucemic reactions. Visceral evidences of capillovenous congestion and increased capillary permeability were not seen in the animals after death. The mechanism of death in "insulin shock" is not the same as that of shock (Moon, *Arch. Path.* 24, 642, 794(1937)). Howard W. Robinson

Examination of the blood of normal and adrenalectomized dogs in relation to cortin treatment. I. I. E. Uyldert, J. Thomassen and L. Waterman. *Endocrinology* 25, 877–84(1939).—No change in the Na or K content of the blood plasma or the nonprotein N or glucose of whole blood was found after the removal of 1 adrenal. A significant difference in these substances was found between normal dogs or dogs with 1 adrenal left intact and bilaterally adrenalectomized dogs. A significant difference in 2-stage adrenalectomized dogs between a good condition and a slight insufficiency was found only in the plasma K. A significant difference exists between slightly insufficient and insufficient dogs only in the nonprotein N. The sharp difference between various degrees of insufficiency, which can be observed from the clinical symptoms of appetite and body temp. cannot be deduced from changes in compn. of blood. II. L. Waterman, I. E. Uyldert, J. Thomassen and F. Oestreicher. *Ibid.* 885–7.—Adrenalectomy produces no significant changes in either the red or white cell picture. Felix Saunders

Effect of a single injection of thyroxine on carbohydrates, protein and growth in the rat liver. Richard Sternheimer. *Endocrinology* 25, 899–908(1939).—The changes in chem. compn. and histological structure of the rat liver vary according to the time elapsed after the injection of thyroxine. The chem. changes consist in a loss of glycogen in the liver and the entire animal, followed, beginning 48 hrs. after injection, by an increase above normal of these values. There is a marked rise in liver protein in the 1st period and, later, a decrease of liver protein to values still above normal in linear proportion to the increase in liver glycogen. Liver sugar, blood sugar and lactic acid content of the liver remain unchanged during the 1st period but rise later, simultaneously with the glycogen. Fresh wt. and dry wt. of the liver increase. The loss in liver glycogen, increase in liver protein and liver size begin before O consumption rises, i. e., during the latent period. The variations in carbohydrates observed in the liver present a close analogy to changes described in growing tissues and it is concluded that liver growth takes place under the conditions of these expts. Felix Saunders

The effects of adrenaline and of nerve stimulation on the mechanical and electric responses of uterine muscle. Robert S. Morison. *Am. J. Physiol.* 128, 372–81(1940). E. D. Walter

The effect of choline on the fatty liver of carbon tetrachloride poisoning. H. M. Barrett, C. H. Best, D. L. MacLean and Jessie H. Ridout. *J. Physiol.* 97, 103–6(1939); cf. *C. A.* 29, 6651⁴.—Rats maintained on a diet low in lipotropic factors with an amt. of added choline sufficient partially to prevent the increase in liver fat due to a low-choline diet develop very fatty livers during the 20-day period after the administration of CCl_4. Animals poisoned with CCl_4 and fed the same diet, with the addn. of excess choline, have almost normal livers at the end of the same period. The results suggest that choline or other lipotropic factors are essential for the removal of the excess fat which accumulates in the livers of rats as a result of CCl_4 poisoning. E. D. Walter

Blood plasma proteins as influenced by intravenous injection of gum acacia. II. Production of chronic hypoproteinemia. Charles L. Yuile and Ralph E. Knutti. *J. Exptl. Med.* 70, 605–13(1939); cf. *C. A.* 33, 2590⁹.—By repeated weekly intravenous injections of gum acacia solns. in dogs over periods of 4–5 months, it has been possible to maintain plasma protein concn., and total circulating protein at very low levels. If sufficient nos. of such injections are given and then discontinued, plasma protein concn. will remain below the normal limits for several more months; acacia remains in the blood during this time. Reduction of fibrinogen concn. in such animals is out of proportion to and more marked than the changes in plasma protein concn.; this would indicate interference with liver function. Globulins are reduced to a greater extent than albumin after a single injection of gum acacia, although both diminish; this cannot be accounted for by a decrease in fibrinogen alone; after 14–16 weekly injections, both albumin and globulin are more profoundly reduced. During injection periods in such animals, it has not been possible to control quantitatively the dietary intake, a complication which has made it difficult to ascertain the effect of various protein diets upon the protein-acacia balance. The changes described, however, have taken place regardless of various types of animal protein diets. C. J. West

Attempt to isolate the virus of grasserie of the silkworm by ultracentrifugation. A. Paillot and A. Gratia. *Arch. ges. Virusforsch.* 1, 120–9(1939)(in French).—Particles of the virus causing grasserie in silkworms were allegedly isolated from the blood and infected tissues by centrifugation and fractional ultracentrifugation. The virus is about 100 mμ in size, i. e., between tobacco-mosaic virus and vaccine virus. In 0.5% NaOH soln., it presents a cubic system of agglomerations of rhombic dodecahedrons under the ultramicroscope. Crystals differing from those of the virus were isolated from the normal tissue fluids of the silkworm. J. Pinchack

Vitamin C and the histophysiology of the hypophysis of

the Selachii. Gregorio Castigli. *Pub. staz. zool. Napoli* 17, 183-92(1939).—Vitamin C was best detd. in the hypophyses of *Scyllium stellare*, *S. canicula* and *Mustelus laevis* histochemically by a $AgNO_3$ method slightly modified from that of Giroud and Leblond (*C. A.* 28, 6181[8]; 29, 6937[2]; 30, 7611[5]). The $AuCl_3$ reduction method of Tonutti (*C. A.* 32, 2268) was less satisfactory. In the anterior lobe the vitamin C reaction is very weak in young animals especially in the chromophobic cells, but increases with maturity and sexual activity until it is strong in both chromophobic and chromophilic cells. The amt. of vitamin C is apparently proportional to the amt. of hormone produced. Within individual cells, the reaction is localized in the zone of Golgi. The intermediate lo be generally has a weaker reaction than the anterior lobe. The echinochrome of *Arbacia* eggs also gives a pos. reaction for vitamin C. 23 references. W. C. Tobie

Effect of halogenated hydrocarbons on eggs of *Toxocara canis* (Lucker) 15.

H. A. LEPPER

Variations and reasons for the variations of the iodine content of the air in Central Europe and their importance for the iodine content of foodstuffs. H. Cauer. *Beiheft Z. Ver. deut. Chem.* No. 34, *Angew. Chem.* 52, 625-8 (1939).—A comprehensive treatise and evaluation of available statistical material developed by C. and other investigators covering the period of about 1923 to 1938. General findings are that a considerable reduction in I content occurred in the last decade. References.

Karl Kammermeyer

Over two thousand estimations of the pH of representative foods. Milton A. Bridges and Marjorie R. Mattice. *Am. J. Digestive Diseases Nutrition* 6, 140-9(1939).—In tabulated form 2100 detns. of the pH of over 400 representative foods are presented. Edward Eagle

Micro-Kjeldahl determinations on foods. Oskar Steiner. *Z. Untersuch. Lebensm.* 78, 300-4(1939). Data on 17 foods are tabulated. The advantages of the method are discussed. M. M. Piskur

Electrochemical determination of small amounts of copper and of lead in food products. M. S. Zakhar'evskiĭ. *Voprosy Pitaniya* 7, No. 4/5, 180-8(1938); *Khim. Referat. Zhur.* 2, No. 4, 84(1939).—The method is based on the measurement of the amt. of electricity which is passing through the circuit Pb-soln.-metal during the soln. of the metal under investigation. Pt wires, having a surface of 0.35 sq. cm. and sealed into glass tubes, are used as electrodes. The Cu in the sample is deposited on an electrode, which is then immersed in a glass contg. a 0.1 *N* soln. of $CuSO_4$ in a 0.2 *N* soln. of CH_3COOH. An auxiliary Pt electrode is placed in the same glass. Both electrodes are connected to a milliammeter. By measuring the current strength and the time, the amt. of electricity passed through the circuit during the soln. of the metal is detd. As little as 0.02 mg. of Cu can be detd. The error is about 10% at a Cu content of 0.01 mg. The Pb is sepd. by electrolysis as PbO_2. A mixt. of equal vols. of normal CH_3COOH, of water and of satd. solns. of CH_3COONa and KNO_3 was used as solvent. Pb can be detd. in the amt. of 0.01 mg. with an error of about 10%. W. R. Henn

Electrometric determination of the titrated acidity in dark-colored liquids. V. A. Rush and S. S. Aksarina. *Voprosy Pitaniya* 1938, No. 4/5, 164-72; *Khim. Referat. Zhur.* 2, No. 4, 84-5(1939).—The electrometric method of titration (with quinhydrone) is recommended for detn. of the acidity of food products. Results of expts. for the detn. of the titrated acidity of sauces, tomatoes, jams and berry preserves are given. W. R. Henn

Food poisoning due to staphylococci with special reference to staphylococcus agglutination by normal horse serum. Glenn G. Slocum and B. A. Linden. *Am. J. Pub. Health* 29, 1326-30(1939). J. A. Kennedy

Simplifying the determination of the moisture content of grain by a preliminary drying. P. Chatskiĭ. *Spirto-Vodochnaya Prom.* 1938, No. 9, 40-1; *Khim. Referat. Zhur.* 2, No. 2, 131(1939).—Instead of the formula for the detn. of the moisture content of grain $W = [1 - (bd/ac)]\ 100\%$, the use of a special table is recommended. For const. wts. of the sample (15 g. for the preliminary and 3 g. for the second drying) a value for the total moisture content is found in the table directly. The results can be made more accurate by interpolation.

W. R. Henn

Protection of cereal seed from the granary weevil by disinfecting agents. E. Reinmuth and H. A. Kirchner. *Anz. Schadlingskunde* 15, 115-17(1939).—The com. organomercury seed disinfectants tested were Abavit Neu (I), Germisan (II) (cf. Saillard, *C. A.* 29, 4888[8]), and Ceresan UT 1875a (III) (cf. Brentzel, *C. A.* 33, 9522[6]), used dry at the rate of 200 g./100 kg. wheat, and as 0.1% solns., the grain being soaked 30 min. and then dried. To 400 g. of grain, after treatment with the resp. disinfectants, 100 adult weevils [*Calandra granaria*] were added, and the infested portions were placed at 19-20° for 143 days, one complete series being left undisturbed and another agitated twice weekly. Solns. of II and III proved valueless, for the increase in weevils was in no case less than that in the untreated control. The soln. of I was more satisfactory, allowing an increase of but 52-125% in no. of weevils. The dry disinfectants were much more effective: III allowed an increase of 37-65% in no. of weevils, and I and II allowed no reproduction and killed all. After 70 days more the germination of the treated and untreated infested wheat was compared with that of weevil-free untreated wheat which germinated about 95%. Germination of the infested, untreated wheat had decreased about 10%, that treated with III showed no change, that with II a decrease of about 5% with 8% showing injury to the coleoptile, and that with I no change. Thus treatment with dry I is most satisfactory from all standpoints. Agitation of the grain produced no appreciable deviation in results. Edwin J. Seiferle

The determination of the flour yield from the starch content in grain. B. S. Dmitriev and P. I. Demkovskiĭ. *Trudy Odesskogo Inst. Tekhnol. Zerna i Muki im. I. V. Stalina* 1938, 69-80; *Khim. Referat. Zhur.* 2, No. 2, 131 (1939).—The content of starch in grain decreases fairly uniformly from the center to the periphery. Therefore, the detn. of starch can characterize the purity of the grinding. Starch in the flour was detd. by the polarimetric method of Evers. The yield of flour cannot be accurately detd. from the starch content in the grain for the tech. chem. production control, because of the necessity for the detn. of corrections for the optical active carbohydrates in the different grades of grain. W. R. Henn

The pigments of grain and a method for the determination of the quality of flour from the color of its alkaline extracts. N. I. Ozolin. *Trudy Odesskogo Inst. Tekhnol. Zerna i Muki im. I. V. Stalina* 1938, 56-68.—In wheat there were found a yellow and a red pigment, which were extd. from flour by an alc. soln. of a base. Curves of the "basic no." were obtained from the colorimetric study of these exts. These curves were the higher the lower the quality of the flour. By the method of the "basic no." the quality of flour in baked bread can be detd. **A colorimetric method for determination of corn flour in mixture with wheat flour.** *Ibid.* 81-8.—The method is based on the different contents of tryptophan in the protein complexes of wheat and corn. The flour is treated with fuming HCl to which alc. has been added and the amt. of corn flour in the HCl soln. (which acquires a characteristic red-

violet color) is detd. colorimetrically. Through *Khim. Referat. Zhur.* 2, No. 2, 131 (1939). W. R. Henn

Conditioning of hard wheat. P. G. Demidov. *Trudy Odesskogo Inst. Tekhnol. Zerna i Muki im. I. V. Stalina* 1938, 21–38; *Khim. Referat. Zhur.* 2, No. 2, 131(1939).—The cold and the hot methods of conditioning cause a no. of phys. and chem. changes in the grain (softening of the endosperm, increase of the water-absorption properties, activation of the enzymes and increase of the quality of gluten) which improve the milling properties of the grain. The baking properties of flour are damaged by the hot method and improved by the cold method of conditioning. W. R. Henn

Saccharification in wheat flour. A. Ostrovskiĭ. *Biokhimiya Khlebopecheniya* 1, 23–38(1938); *Khim. Referat. Zhur.* 2, No. 3, 134(1939).—Starch maltose is the chief source of gas formation in dough. The amt. of sucrose + reducing sugars is insufficient to produce the necessary amt. of gases. The increase of the diastatic activity of flour (according to Ramsey) increases the quality of bread only if this increase of the diastatic activity is not caused by the presence of α-amylase in flour. In some cases it is necessary to det. separately the activities of α- and of β-amylases. W. R. Henn

The thermal treatment and the drying of flour. N. I. Ogolin. *Trudy Odesskogo Inst. Tekhnol. Zerna i Muki im. I. V. Stalina* 1938, 3–20; *Khim. Referat. Zhur.* 2, No. 2, 132(1939).—Heating of some grades of flour to 60° for 1 hr. improves the bread-baking properties, owing to a change of the colloidal properties of gluten. W. R. Henn

Effect of various conditions of storage on baking quality of flour. A. G. McCalla, J. D. McCaig and A. D. Paul. *Can. J. Research* 17, C, 452–9(1939); cf. *C. A.* 31, 5047⁵.—Flour stored in sealed containers in a refrigerator at 2° did not change in quality for 22 months after milling. Similar flours stored in sealed containers at room temp. deteriorated significantly within 3 months, while a third lot stored in small bags at room temp. showed first a definite improvement and then rapid deterioration. At the end of 22 months flours stored in sacks were much the poorest. Acidity of all flours increased with storage, but this detn. was of little value in estg. flour quality. J. W. Shipley

A rapid method for the determination of moisture in bakery products. A. G. M. Kul'man, *et al. Vsesoyuz. Nauch.-Issledovatel. Inst. Khlebopekarnoĭ Prom. S. S. S. R.* 1938, 36 pp.—It is proposed to heat the sample with a nonvolatile liquid which remains const. in wt. during the detn. of water (sunflower-seed oil, cottonseed oil, paraffin). The oil is heated for 1–2 hrs. at 200° until no more foam is formed, and then kept in well-sealed glass jars. The sample is heated with the oil in an open Fe crucible in an elec. drying oven or on a sand bath at 185–65°. The moisture is detd. from the loss of wt. A 0.2–0.3% agreement of results in parallel detns. was obtained, and results on 90 samples of flour, dough and bread agreed with those obtained by drying at 105°. The detns. (including all operations) take about 20–5 min. W. R. Henn

Biennial reviews of the progress of dairy science. Section E. Bacteriology and mycology applied to dairying. A. T. R. Mattick, E. R. Hiscox and J. G. Davis. *J. Dairy Research* 10, 514–49(1939).—The following phases of the subject are discussed: milk control in relation to technique; coli-aerogenes group and spore-forming bacteria in milk and milk products; bacterial metabolism, protein and fat metabolism, nutrition, respiration, fermentation and N metabolism of the lactic acid-producing organisms; starters; cheese ripening; cheese faults; butter; pasteurization; canned and dried milk products; and ice cream. A. H. Johnson

Kay and Graham's phosphatase test. A. Modifications in technique. B. Effect of bacterial growth. F. K. Neave. *J. Dairy Research* 10, 475–84(1939).—By the use of Na hexametaphosphate it was possible to eliminate the final filtration in the phosphatase test and thus appreciably to shorten the time required for the test. It was necessary to avoid direct sunlight during that part of the test in which Folin's reagent is in use. Other minor precautions are also mentioned. The pH of the milk samples tested varied naturally before pasteurization from pH 6.5 to pH 6.9 without affecting the validity of the test. The test was also unaffected by the presence in milk of bacteria which produce reducing substances or which hydrolyze the substrate (Na phenyl phosphate) unless the organisms are present in very large nos. The addn. of mercuric chloride, one part in 10,000 parts of milk, could be used without any significant effect on milk phosphatase and increased the keeping time of the milk from 1 to 8 days. Concn. of 1 to 5000 or greater had a destruction or retarding action on the phosphatase. A. H. Johnson

A rapid phosphatase test. A. Adaptation of Scharer's modification to pasteurizing conditions in Great Britain. B. A study of factors influencing the reliability of the test. R. Aschaffenburg and F. K. Neave. *J. Dairy Research* 10, 485–97(1939).—By adapting Scharer's "10 minute field test" to British conditions of pasteurization, an accurate phosphatase test has been evolved requiring less than 1.5 hrs. for completion. The method is described in detail. A small percentage of anomalies was detected when the new method was applied to the examn. of pasteurized samples bulked from small quantities of milk (less than 100 gal.). This led to a study of several factors thought to be the likely cause of such anomalous results. No correlation was found between the phosphatase surviving heat-treatment and the stage of lactation when milk from individual cows and from small groups of animals was tested, with the possible exception of the early stages of lactation when the enzyme concn. before and after heating was frequently found to be too low. Pasteurized milk from animals suffering from mastitis tended to give abnormally high results for the phosphatase test. The amt. of residual phosphatase was subject to considerable fluctuation. A. H. Johnson

A slide rule especially constructed for the rapid determination of the simplified real molecular constant of milk. P. Gallot. *Bull. soc. ind. Rouen* 66, 346–7(1938).—Description of a slide rule especially constructed by G. for the detn. of the simplified real mol. const. of milk, representing the lb. of lactose isotonically equiv. to the sum of the milk crystalloids. J. C. Jurrjens

The lipides of milk. II. The fat acids of the sphingomyelincerebroside fraction. Floyd E. Kurtz and Geo. E. Holm. *J. Dairy Sci.* 22, 1011–15(1939); cf. *C. A.* 28, 6861⁹.—The acetone-insol., ether-insol. lipides of milk were isolated and found to consist of approx. equal parts of sphingomyelin and cerebrosides. Their amt. was approx. 15% of that of the ether-sol. lecithin-cephalin material. The fat acid constituents were analyzed and found to consist chiefly of lignoceric acid (approx. 80%) which was isolated and identified. The other 20% of acids was found to be a very complex mixt. of satd., unsatd., hydroxy satd., and presumably hydroxy unsatd. acids; with the exception of myristic acid none was present in sufficiently great concn. to make isolation possible with the limited supply of available material. It is indicated that myristic acid is present in a concn. of less than 1%. The presence of lignoceric acid in high concn. and the indicated nature of the other acids are in harmony with the nature of the acids of sphingomyelin and cerebrosides obtained from other sources. A. H. Johnson

The effect of light on the vitamin C of milk in different containers. J. Houston, S. K. Kon and S. Y. Thompson. *J. Dairy Research* 10, 471–4(1939).—Brown glass bottles allowed little destruction, green glass bottles considerably more, and wax-impregnated cartons still more. In clear glass bottles only half as much vitamin C remained as in the wax-impregnated cartons. A. H. Johnson

Cooked and oxidized flavors of milk as affected by ferrous iron. I. A. Gould. *J. Dairy Sci.* 22, 1017–23(1939).—The heating of milk momentarily to 80–82° or above prevents the development of an oxidized flavor as induced by 2.8 p. p. m. of ferrous Fe. This occurs irrespective as to whether the Fe is added before or after the heat-treatment. The appearance of a strong cooked flavor at these temps. is correlated with the failure of the oxidized flavor to

develop. The liberation of sulfides is related to the cooked flavor and prevents the development of the oxidized flavor. The "critical" temp. is different for milk contg. added ferrous Fe than for that contg. added Cu, owing to differences in their abilities to form complexes with the substance supplying the heat-labile S or due to differences in their oxidizing properties. A. H. Johnson

Proteins in whey. Margrethe Sørensen and S. P. L. Sørensen. *Compt. rend. trav. lab Carlsberg*, Sér. chim. **23**, 55-99(1939).—Pptn. of the casein with 100 cc. *N* AcOH removes 4500 mg. of N and 230 mg. of P from skim milk of av. N content of 5500 mg. and av. P content of 250 mg. per l., leaving 1000 mg. of N and 20 mg. of P in the whey. Pptn. of casein with $(NH_4)_2SO_4$ (I) removes as much N and P as does AcOH when 32.8 g. and 33.5 g., resp., per 100 cc. of milk are added. N and P are removed at a much slower rate per g. of salt added than prevails up to the addn. of the 32.8- and 33.5-g. amts. In this range a slimy fraction, formerly designated lactoglobulin, first appears. This fraction produced "*lactomucin*" (II) of green color and a red substance (III). Removal of this uncrystallizable mixt. and the addn. of more I permitted the sepn. of 2 crystallizable fractions, (1) Palmer's cryst. globulin-like substance (*C. A.* **28**, 3091[6]) (IV), obtained in both a cryst. and gelatinous form, and (2) an "insol. substance" (V). The major part of the whey proteins begins to ppt. when a concn. of 60 g. of I per 100 cc. is reached and is complete on adding 80 g. One-step addn. of I to skim milk of either pH 6.7 or 5.4 left equal amts of N in the whey. Fractional pptn. (fractional addn. of I alternated with filtrations) leaves more N in the whey than one-step addns. of the same amt. of I, indicating co-pptn. in the former method. "Lactomucin" was obtained from whey by bringing the concn. of I to 65%, the ppt. washed with 65% I, dissolved and filtered, the soln. of pH 5.8 contg. 1/4 of the N of the whey; addn. of I to this soln. to 45% yielded a green ppt. The filtrate, brought to 48% I, yielded a greenish fraction, and the second filtrate brought to 51.4% I yielded a second greenish ppt. These 3 ppts. were combined and H_2O was added, leaving II, a green, thick, oily mass, slowly sol. and when pptd. with I at 40% and washed with 40% I was found to have 0.04 mg. P, 0.618 mg. carbohydrate, 0.138 mg. glucosamine and 0.019 mg. tryptophan per mg. of protein N. The portion sol. in 40% I was pptd. by increasing I to 70%, repptd. to free it from lactose; it was found to have P 0.015 mg., carbohydrate 0.325 mg., glucosamine 0.281 mg. and tryptophan 0.220 mg. per g. of protein N. The green color of these fractions is removed on adding NH_4 but reappears on adding acid. Increase of I to 57.3%, 58.3%, 62% and 68.5% in the filtrate from the first green ppt. yielded successive red fractions, which were combined and repptd. to yield finally III, having P 0.017 mg., carbohydrate 0.153, glucosamine 0.102 mg. and tryptophan 0.653 mg. per g. of protein N. The red fractions account for about 80% and the green fractions for about 20% of the protein N of this part of the whey proteins. II is difficultly sol. in H_2O and in neutral salt soln.; III is sol. in H_2O. IV, contg. 0.2–0.3 mg. tryptophan per mg. of protein N and no P or carbohydrate, is obtained, after removal of II and III, by pptg. all of the remaining protein (lactalbumin proper) with I, repptg. to remove lactose and finally dissolving in H_2O, dialyzing and crystg. at room temp. IV is insol. in H_2O but sol. in weak salt soln., accounts for 50% of the lactalbumin N, and crystallizes after seeding to long needles or prismatic crystals. A gelatinous fraction is obtained from the soln. of lactalbumin proper by acidifying with H_2SO_4 to pH 4.6 and adding I to 45%, filtering and allowing the filtrate to stand until it jells. This fraction reverts to IV by adding I at pH 6. Crude IV contains V which has somewhat more tryptophan and accounts for about 10% of the lactalbumin fraction proper. In another series of expts. to obtain the cryst. fractions of lactalbumin (probably IV and V), estd. to total one-fifth of the lactalbumin fraction, the authors had to resort to fractional dissolving of the protein in gradually decreasing concns. of I to free the cryst. portions from amorphous material. The protein soln. is first half satd. with I and filtered. Seeding of the filtrate and gradual increase of I to 60% produced a mixt. of amorphous and cryst. material which is washed and stirred with gradually decreasing concns. of I, until a concn. of 50% is reached. On seeding, these solns. yield on long standing and gradual increase of I to 65%, 2 well-defined, P-free and carbohydrate-free, cryst. substances (needles), contg. 0.4 mg. tryptophan per mg. of protein N. No crystn. could be induced without this fractional treatment. Photographs of the crystals are shown. Detns. of protein N, P, carbohydrate and glucosamine (by methods published earlier by one of the authors) and the detn. of tryptophan by the Komm and Bohringer method (*C. A.* **17**, 2125), in the examn. of the fractions, were applied after sepn. of the proteins by tannic acid since it was found that tannic acid, in contrast to heat or CCl_3CO_2H, ppts. these fractions completely over a wide range of concn. H. K. Salzberg

Factors affecting the solubility of milk powders. IV. The influence of speed and duration of stirring on solubility with a description of a rapid method for solubility determinations. G. R. Howat, J. A. B. Smith, R. Waite and N. C. Wright. *J. Dairy Research* **10**, 198-514(1939); cf. *C. A.* **29**, 3053[4].—The effects of alterations in the duration and speed of stirring on the apparent soly. of milk powders were investigated. It was concluded that shaking of the powder reconstituted in a 10% mixt. for 30 sec. was sufficient to dissolve the truly sol. portion of the dried milk, but that the protein that had become denatured during the drying process tended to pass into soln. with increasing speed, and duration of stirring. A rapid method for estg. the soly. of milk powders on a total solid basis involving only 1-min. shaking is described and discussed. The sediment method frequently used in industry as a guide to the soly. of dried milks is compared with the rapid method. At higher solubilities the sediment vol. may serve as a guide to small changes in soly., but in the lower soly. ranges its usefulness was limited. The washing of the sediment with one or more changes of water merely introduced addnl. errors into this method of soly detn. The detn. of soly. by detg. protein in the centrifuged reconstituted milk was not as good an index of soly. as detg. the total solids in the soln. The soly. of the proteins in roller powder was 20 to 30% higher at 50° than at 20° under the same conditions of reconstitution. A. H. Johnson

Butter in cold storage. Studies on the keeping quality and oxidation. O. R. Overman, O. F. Garrett and H. A. Ruehe. *Ice and Cold Storage* **42**, No. 498, 141-2(1939).—The length of time that elapsed from initial exposure of fat to O until the beginning of apparent vol. absorption varied greatly for different butters and even for samples of the same butter after different periods of storage. No consistent relation between the initial quality of the butter or the time in storage and the induction time could be observed. For some butters the induction period was shorter after many months of storage, for some butters it was not shorter and for some butters it was longer after storage. Butter to which 0.25% of $CuSO_4$ had been added showed a much shorter induction period than did other samples. The I absorption no. showed no correlation with keeping quality. Butters made during the months of May to September gave I absorption nos. ranging from 36.0 to 41.8 while butters made in December gave values ranging from 30.24 to 33.16. A. H. Johnson

Judging the weight decrease of printed butter and margarine. A. Schloemer. *Z. Untersuch. Lebensm.* **78**, 298-300(1939); cf. *C. A.* **34**, 825[1].—General discussion. M. M. Piskur

Margarine production in Buenos Aires. Abel Sánchez Díaz. *Rev. soc. bras. quím.* **8**, 95-106(1939). E. S. G. Barron

Applying fat characteristics for distinguishing between sheep and cow milk cheese. Alfons Schloemer and Erich Langmann. *Z. Untersuch. Lebensm.* **78**, 293-8(1939).—Means of distinguishing Roquefort cheese and blue cheese or other substitutes of the former were investigated. The butyric acid and the isoöleic acid value of fat of sheep and cow milk are practically the same. The fat from sheep milk cheese had an appreciably greater

"total value" and residue value than the fat from cow milk cheese. These characteristics can be used to differentiate the fats. About 38 references. M. M. Piskur

Investigation on fruit products. XV. Experiments on the production of unfermented apple juice. 1938. Vernon L. S. Charley and V. E. Sills. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 188–203(Pub., 1939); cf. *C. A.* **33**, 765[4,7,8].—Apple juice produced from culinary (75%) and cider (25%) fruits was processed in 26 different ways into bottles of varying degrees of sterility. Satisfactory sterility was obtained in 98% of bottles filled by the cold sterilization process, 100% of bottles in which the juice had been pasteurized in the container and in varying percentages of the flash pasteurized juices. Pasteurization at 185°F. for 30 sec. followed by immediate cooling and filling at 160°F. into hot steamed bottles gave a satisfactory product, but the sterility of the other products was affected to a considerable extent by the flash 3 pasteurization and filling temps. and by the sterility of the bottles into which the juice was filled. The flavors of juices pasteurized at the highest temps. were preferred by a flavor panel both to those of juices pasteurized at lower temps. or in bottle, and also to the cold-pressed juice. The best sterilization of washed and rinsed bottles was obtained by finally rinsing with a 2% SO_2 soln. K. D. J.

Ice crystals in frozen fruits. J. G. Woodroof. *Ice and Cold Storage* **42**, No. 498, 139–40(1939).—The solidity, rigidity or firmness of tissues usually frozen appears to be due to the distribution and state of the liquid in the cell, possibly in the form of surface films between granules, microsomes or droplets of various kinds as well as to the presence of vascular bundles, thickened walls or cuticle. The removal of a part of this water by freezing at moderately low temp. and later restoring on thawing is partly reversible and to that extent is not injurious; while the complete removal at very low temp. seems to ppt. the colloids and is irreversible. However, the cell walls of some fruits and vegetables are easily broken by ice crystals on freezing. Cell-wall rupture is much more frequent in some tissues than in others and is assocd. with the nature of the material frozen, the time and the rate of freezing and the size, shape and location of the ice crystals. The cells of rhubarb are much more inclined to push apart than cells of other plants of this group. The cells of stringbean pods sometimes sep. rather than rupture, but those of spinach, asparagus and broccoli rupture badly. Ripe strawberries, raspberries, dewberries, peaches, figs and cherries are difficult to freeze because of the ease with which their colloidal complex is changed. A short interval between formation of the first ice crystals and the complete hardening of the product is essential for the preservation of texture, palatability and satisfactory superficial appearance of fruits and vegetables. A. H. Johnson

Control of wastage of citrus fruit by impregnated wrappers on a commercial scale. A. Farkas. *Hadar* **12**, 227–31(1939); cf. *C. A.* **33**, 1827[6].—The *toxicity of biphenyl* was studied by feeding it to a rat and a monkey at rates corresponding to 7 and 2.5 g. per week for a man weighing 70 kg. No ill effects on the animals were observed. A man consumed 435 mg. in 13 weeks without effect. Biphenyl dust in the air can be tolerated for several days 8 without harm except a transient smarting of the eyes. It is concluded that biphenyl is harmless and that quantities likely to be encountered in making or using impregnated wraps can do no harm. Marketability of fruit is unimpaired by use of these wrappers. Fruit in wrappers impregnated with biphenyl shows much less spoilage and can be stored longer. Shipping and storage expts. are described. Colin W. Whittaker

Effect of storage temperature on peaches. M. H. Haller and P. L. Harding. *U. S. Dept. Agr., Tech. Bull.* 680, 32 pp.(1939).—Peaches cannot be held in storage 9 for more than 2–4 weeks, depending on the variety and growing conditions, without serious loss of dessert quality or the development of breakdown. There is generally a marked loss in the flavor of peaches ripened at 50°F. as compared with those ripened at higher temps. Internal breakdown or low-temp. injury develops earlier at 36° and 40°F. than at lower or higher temp. A temp. of 32°F. is recommended for the storage of peaches. W. H. R.

The Long Ashton contribution to the development of pure fruit products. B. T. P. Barker. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 213–19 (Pub., 1939).—A discussion of developments in the prepn. of cider and apple juice and the utilization of cull apples. K. D. Jacob

World developments in fruit-juice production and the present English industry. Roger C. Morel. *Ann. Rept. Agr. Hort. Research Sta., Long. Ashton, Bristol* **1938**, 220–5(Pub., 1939). K. D. Jacob

Silver determination in catadynized acids and fruit-juice lemonades. O. Noetzel. *Z. Untersuch. Lebensm.* **78**, 315–21(1939).—The application of the Feigl reaction (*C. A.* **22**, 4080) for colorimetrically detg. Ag in acids and lemonades was investigated. Ashing followed by fusion with $NaNO_3$ is suitable for destruction of the org. material. M. M. Piskur

Impressions of the German apple-juice industry. Vernon L. S. Charley. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 204–12(Pub., 1939).—See *C. A.* **33**, 7914[3]. K. D. Jacob

Fruit pectins—their chemical behavior and jellying properties. C. L. Hinton. *Dept. Sci. Ind. Research* (Brit.), *Food Invest., Special Rept.* No. **48**, 96 pp.(1939). —Pectin in a food ext. can be detd. by pptn. in 50% acetone. The ppt. is dissolved in warm H_2O and repptd. in acetone with NaCl to assist pptn. A more exact detn. is made by dissolving the first acetone ppt. and repptg. it as Ca pectate. The soln. is treated with 0.5 *N* NaOH overnight, then with *N* acetic acid 5 min., and then with *M* $CaCl_2$. It is boiled with water to remove Cl and dried first in a steam oven and then at 100–110°. Jellying power of the pectins is detd. by the strength of the jelly formed at a pH of 2. The term pectin includes many compds. with minor variations in mol. compn. Their free acidity, pH and alk. ash content vary with the extent to which metallic bases, united with the acidic groups, were removed in the prepn. Detn. of total acidic groups showed that the galacturonic acid units make up 75–95% of the mol. All pectins have a slight reducing action on alk. I solns. indicating a chain structure for the mol. This is the only chem. property that can be correlated with jellying power. Long boiling reduced jellying power and increased I reducing power, but an 80° temp. had less effect. Small amts. of acid had little effect. Pectase action was harmful because the deesterified pectin formed insol. Ca salts. The loss of CH_3OH affects the pH at which jellying power is best. Addn. of alkali or salts affects the action of pectin with metallic salts. The jelly- 7 ing power varies with the type of fruit, the heat to which it has been subjected, pH conditions, and pectase action. The methoxyl content is 11–12%. Amy LeVesconte

Unification of methods of analysis of tomato conserves. Franco Emanuele. *Ind. ital. conserve* **14**, 83–8(1939).— Standards and analytical methods are discussed. O. W. Willcox

The calcium and phosphorus contents of vegetables cooked in fat. Hsi Hsuan Yü and Margaret L. Fincke. *J. Home Econ.* **31**, 711–13(1939).—Asparagus and peas lost no Ca or P and celery cabbage lost no Ca when cooked by the Chinese method of sautéing. Amy LeVesconte

The vitamin C content of honey. Jenö Becker and R. F. Kardos. *Z. Untersuch. Lebensm.* **78**, 305–8(1939).—On the basis of animal tests (biol. test) it was demonstrated that the reducing component of honey is not vitamin C. Fifteen references. M. M. Piskur

Volumetric estimation of lac on glazed candies. Nicholas M. Molnar and Joseph Grumer. *Ind. Eng. Chem., Anal. Ed.* **11**, 673–4(1939).—The lac is dissolved in alc. An equal quantity of water is added and the boiling mixt. is titrated with Na_2CO_3. Phenol red is the indicator. Org. acids interfere but these can be detd. in the aq. ext. Fatty acids can be removed with CCl_4. A. LeVesconte

Determination of color components of paprika spice. L. v. Cholnoky. *Z. Untersuch. Lebensm.* **78**, 157–61

(1939).—A proximate method for detg. the various carotenoids, i. e., carotenes, kryptoxanthin, capsanthin and capsorubin of paprika is a combination of Tswett's chromatographic analysis based on selective adsorption on $CaCO_3$ and $Ca(OH)_2$, with the Kuhn and Brockmann's (*C. A.* **26**, 3533) and other comparative methods of colorimetrically evaluating the amt. of each eluted from sections of the adsorbate. Data on products of various geographical sources, com. products, and the effect of storage on the coloring constituents are tabulated. There was a 5–13% loss of pigment in the ground product after 6 months' storage. M. M. Piskur

Determining the cacao hull contents of cacao powder. A. Müller. *Z. Untersuch. Lebensm.* **78**, 150–6(1939).—The crude fiber of 10 com. cacao products was 0.55–0.92%. A 5.01–9.88% increase in crude fiber occurred per 1% addn. of hull; cacao hulls from different geographical sources contribute different amts. of fiber in the test. M. M. Piskur

The maximum water content of pressed cacao butter. Heinrich Fincke. *Z. Untersuch. Lebensm.* **78**, 314–15 (1939); cf. *C. A.* **33**, 6979[6,3,5].—The moisture content of cacao butter is below 0.03%. M. M. Piskur

Urea as a possible substitute for peanut cake for wintering young stock. C. A. Murray and A. E. Romyn. *Rhodesia Agr. J.* **36**, 554–9(1939).—Feeding expts. indicated that urea can be utilized, at least in part, as a substitute for peanut cake. Nine references. C. W. W.

Comparative value of Napier and Sudan grass when used as soiling crops for dairy cows. L. A. Henke and G. W. H. Goo. *J. Dairy Sci.* **22**, 1007–10(1939).—In expts. comparing green Sudan with green Napier grass as a soiling crop fed to dairy cows, the former proved superior in each test on the basis of quantity of milk produced. Milk production averaged 8.7% higher and roughage consumption 7.2% higher when Sudan grass was fed. The higher production in Sudan grass resulted from a greater intake because of greater palatability and higher nutritive value. Butterfat tests were slightly higher when Napier grass was fed. Analysis of grasses show that Sudan grass was higher in protein, N-free ext. and total nutrients than Napier grass. Sudan and Napier grasses are among the chief grasses grown in Hawaii. A. H. Johnson

The souring of raw disintegrated sugar beets in combination with potatoes for feeding swine. Hans-Joachim Neumann. *Kuhn-Arch.* **52**, 193–205(1939).—Silage prepd. with steamed potatoes and chopped or mashed sugar beets in a ratio of 1:1 or 2.1 makes a suitable feed for swine. These mixts. were free from butyric acid and nitrate N. Very low concns. of ammonia N showed that there was practically no decompn. of protein during the prepn. The ratio of lactic acid to acetic acid was 2.132:1 in the 1:1 mixt. and 2.594:1 in the 2:1 mixt. Potato silage alone had an acid ratio of 1.548:1. The addn. of the sugar beets to the potato silage lowers the pH from 4.10 to 3.74–3.75. C. K. Horner

Poisonous properties of some plants of Western Siberia. G. I. Yavel'berg. *Sovet. Veterinariya* **1938**, No. 3, 75–6; *Khim. Referat. Zhur.* 2, No. 3, 59–60(1939).—Some fodder plants of Western Siberia were exaind. for alkaloids; most of them contained no alkaloids in significant quantities, although some (not formerly classified as alkaloid-contg.) were found to be harmful, e. g., thermopsis. Methods for the detn. of alkaloids and results are given. Content of alkaloids found were *Delphinium laxiflorum* 0.19–0.21; *Veratrum album* 0.13–0.17; *Aconitum barbatum* 0.80–1.00; *Thermopsis lanceolata* 0.52–0.62%. W. R. Henn

Arsenical soils of Waiotapu Valley. Evidence of stock poisoning at Reporoa (Grimmett) **15**. Hydrogenation of mixed oils (de Leon, Agdeppa) **27**. Substitute for lab. food grinder (Davis) **1**. Extg. grape seed [residue used in stock feed] (Gavrilenko) **27**. Application of H_2O_2 for preservation or refining of beverages (Matui, Yamada) **16**.

1 Paper containers for food products (U. S. pat. 2,176,370) **13**.

Wrapping material for foods, etc. John Eggert and Bruno Wendt (to I. G. Farbenind. A.-G.). U. S. 2,171,427, Aug. 29. Sheets of wrapping material are used such as those of gelatin, paper or regenerated cellulose contg. a 1,3,5-triazine deriv. at most but slightly colored, such as 2 the Na salt of 1,4-bis(2-hydroxy-4-phenylamino-1,3,5-triazin-6-ylamino)benzenedisulfonic acid. Numerous 1,3,5-triazine derivs. are listed which may be used for protecting wrapped materials from the action of ultraviolet light.

Concentrated emergency ration. Paul P. Logan. U. S. 2,176,086, Oct. 17. A concd. food adapted to withstand temps. up to about 55° is formed of ingredients such as bitter chocolate (contg. 54% cacao fat) 160, sucrose 160, 3 skimmed milk powder 70, raw oat flour 30, added cacao fat 30 parts and a flavoring of vanillin crystals concentrate.

Ingredient for bakery cakes. Morris B. Katzman (to The Emulsol Corp.). U. S. 2,176,077, Oct. 10. A reaction product of tetraphosphoric acid with an alc. contg. at least 4 C atoms, such as octadecyl or lauryl alc. or coconut oil mixed fatty alcs., is used to give cakes improved texture and grain.

Device suitable for taking samples of milk from tanks, etc. Allan T. Dahlstrom. U. S. 2,177,477, Oct. 24. 4 Various structural and operative details.

Sediment indicator for testing liquids such as milk. John Drew. U. S. 2,177,060, Oct. 24. App. for testing liquids for sediment includes means for trapping a sample of the liquid to be tested, means for holding filtering material in position to pass the liquid sample therethrough, comprising opposed conduits relatively movable into and 5 out of filtering material clamping relation to each other, one of said conduits being connected to said sample trapping means, pneumatically operable means for effecting the relative clamping movement of said conduits, means for connecting said pneumatic means and also said sample trapping means to a source of compressed air, said means including valves for controlling the admission of the compressed air into said connections.

Curing meat. Meyer Moskowitz and Harry Meisel (to Corn Products Refining Co.). U. S. 2,176,144, Oct. 6 17. Fresh meat, such as pork bellies, is treated with a curing compn. contg. salt and dextrose, then subjected to a washing operation, and then treated with H_2O_2 to prevent darkening when fried.

Preserving the natural color of fresh meat. James J. Doyle. U. S. 2,177,519, Oct. 24. Meats such as ground meats are treated with an alkali metal salt of a weak acid 7 such as Na aluminate to give the meat a pH of 7.0–7.4, and may also be treated with a reducing sugar such as dextrose, an alkali metal salt of a sugar acid, a natural metabolic product of a sugar or a substance such as Na benzoate, for inhibiting bacterial and enzymic action.

Tubing (such as sausage casings) from cellulose derivatives. Frank H. Reichel and Augustus E. Craver (to Sylvania Industrial Corp.). U. S. 2,176,925, Oct. 24. App. is described, and a process of producing seamless 8 tubing comprising extruding in the shape of a tubing a coagulable cellulose nitrate dispersed in a solvent comprising alc. and ether into a coagulating and conditioning bath comprising alc. and water, the concn. of alc. in the bath being such that substantially all of the ether in the cellulose nitrate during coagulation is displaced by alc. and water so that the cellulose nitrate is maintained in an uncontracted but completely coagulated condition, applying internal pressure to the completely coagulated and 9 conditioned cellulose nitrate tubing to stretch the same, and converting the cellulose nitrate in the state caused by stretching substantially to cellulose hydrate. Similar procedure may also be used in producing tubing from solns. of other cellulose derivs. such as viscose. Cf. *C. A.* **34**, 886[8].

13—CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

Some new products of 1939. A few of the year's achievements in industrial and medical chemistry. H. E. Howe. *Barron's* **19**, No. 49, 18(Dec. 4, 1939). A. M. P.

Civilian gas masks in other lands. Ed. Smolczyk. *Z. ges. Schiess- u. Sprengstoffw.* **34**, 273–5(1939).—This article contains descriptions and photographs of civilian gas masks of various nations insofar as these have been published. A. L. Kibler

Medical experience of the Americans with chemical warfare gases in the World War. Max Gerchik. *Protar* **5**, 173–9, 199–202(1939).—The object of this article was to discuss the American records of gas casualties with special reference to therapy and aftereffects. Data are given for phosgene, chlorine and mustard gas. The aftereffects of these gases are discussed in considerable detail. A. L. Kibler

Carbon monoxide. Fritz Gehrmann. *Gasmaske* **11**, 97–101(1939).—This is primarily a historical treatment of the toxic effects of CO. It also contains brief directions for treatment of poisoned persons and a brief description of the Auer CO detector. This app. is based on the reaction of CO with a mixt. of I_2O_5 and fuming H_2SO_4, liberating I, which colors the liquid. A comparison of the color with a color card gives the concn. of CO. A. L. Kibler

Accident and sickness prevention in chemical industries. Karl Schildt. *Chem. App.* **26**, 249–52, 269–72, 289–94, 308–10(1939); cf. *C. A.* **33**, 7921[8].—A discussion of accident-prevention measures in German chem. industries. G. W. Stroebe

Dust prevention by use of carbonate minerals. H. Charlton Dod. *Chem. Eng. Mining Rev.* **32**, 57(1939).—Since certain mineral carbonates and oxides carry elec. charges the opposite of those carried by siliceous particles, they may be used as tamping in drill holes. Prepd. cylinders of damp tamping could be supplied. In using carbonate minerals for tamping it is necessary to ensure that the atm. be charged with water vapor. The air of the mine chamber should be filled with water spray before "firing out." The mixed dust of limestone and magnesite is efficacious in the settling of siliceous dust around ore bins, chutes, "crackers," etc., so the use of water is not compulsory. W. H. Boynton

Organic chemistry and the chemical industry (in U. S. S. R.). N. D. Zelinskiĭ. *Shornik "Matem. i Estestv. v S. S. S. R."* **1938**, 465–73; *Khim. Referat. Zhur.* **2**, No. 3, 28(1939).—A review of developments in the last 20 years 7 of the destructive hydrogenation of petroleum products, synthesis of artificial rubber, aromatization of the naphthenes and paraffins, desulfurization of petroleum and shale oils, development of the production of stable dyes, synthesis of chem.-pharmaceutic prepns. production of alkaloids from domestic raw materials, and the synthesis of liquid fuel. W. R. Henn

Film-forming plastics. Effects of solvents, diluents and plasticizers. Frank W. Reinhart and Gordon M. 8 Kline. *Ind. Eng. Chem.* **31**, 1522–9(1939).—Compatibility, flexibility and film shrinkage are given in extensive tables for cellulose triacetate (I), cellulose nitrate, cellulose acetobutyrate, cellulose acetopropionate, hydrolyzed I, ethylcellulose (II), Me acrylate resin, chlorinated rubber, benzylcellulose and isobutyl methacrylate resin, with 39 plasticizers and a wide variety of solvent mixts. The shrinkage of the plastics decreased in the order in which 9 they are given above, being negligible for the last 4. II had the greatest range of soly.; I, least. Shrinkage was increased by the use of certain diluents which have a swelling action on the plastic but the resulting films tended to be brittle. Arnold M. Collins

Preparation of plastic masses on a basis of partially hydrolyzed sawdust. L. V. Gordon, L. N. Kozlovskaya and L. L. Korshun. *Lesokhim. Prom.* **6**, No. 1, 10–12 (1938); *Khim. Referat. Zhur.* **2**, No. 3, 122(1939).—Birch sawdust was treated with an equal wt. of 1.3–1.5% H_2SO_4 soln., dried for 5 hrs. at 110–20°, and mixed with an 2 aq. alk. soln. of resol tar (with a NaOH catalyst, the condensation did not reach the stage of sepn. into layers). The impregnating soln. contained 1.5–2% NaOH soln. in an amt. equiv. to, or slightly exceeding, the amt. required for the neutralization of the acid in the sawdust. The impregnated mass was dried to 4–5% moisture content and pressed at 140–5° under 400 kg./sq. cm. Rolling at 90° for 1.5–2 min. increased the rate of the polymerization and increased the fluidity of the press-powder. The product 3 had av. impact hardness of 5–8 kg.-cm./sq. cm., temporary resistance to bending 450–700 kg./sq. cm., water resistance (wt. added in 24 hrs.) 0.1–0.3%, sp. surface elec. resistance 5×10^{11} ohms, sp. vol. elec. resistance 2×10^{11} ohms, elec. breakdown strength 10.7 kv./mm. The plastic mass can be easily polished and drilled. W. R. Henn

Preparation of plastic masses on a basis of wood fibers. G. A. Kan. *Lesokhim. Prom.* **6**, No. 2, 12–14(1938); 4 *Khim. Referat. Zhur.* **2**, No. 3, 122(1939).—The object of the expts. was to prep. from wood fibers a material of uniform strength in all directions and of greater strength than the original wood material. Pine chips were boiled for 2 hrs. in a 1% alk. soln. at 140°, and ground to small fragments. The fiber mass (yield about 85% of the wood material) was shaped into bricks and air-dried. The bricks were compressed at different temps. and pressures. They possessed satisfactory strength, but were not water-resistant. In order to impart water resistance the mass was impregnated with resol phenol-formaldehyde resin in the form of an emulsion obtained by diln. of an alc. soln. of resin with water or with an alk. soln. of resin followed by treatment with acid. The impregnated samples absorbed water to the extent of 2–15% in 3 days, depending on the thoroughness of the mixture of the fiber with the resin. Pressure of 600 kg./sq. cm. at 160° for 15 min. gave best results. W. R. Henn

Laminated plastics with plywood base. S. P. Krasovskiĭ. *Lesokhim. Prom.* **6**, No. 1, 13–15(1938); *Khim. Referat. Zhur.* **2**, No. 3, 122–3(1939).—Laminated plastics (lignofol) are prepd. by soaking plywood with a soln. of resin in denaturated alc., drying and subjecting to high pressures; a considerable compression of the wood takes place and the resin is converted to an infusible and insol. state. Penetration of the wood decreases with increasing 7 concn. of resin, and increases slightly with duration of soaking (5–20 hrs.) and with decreasing thickness of the plywood (2–0.5 mm.). The optimum temp. of compression is below the optimum for the formation of the *C* stage (170–80°). The optimum pressure is not lower than 300 kg./sq. cm. The optimum time of compression is 4 min. for 30-mm. samples and 5 min. for 50-mm. samples. Lignofol of an equal vol. wt. with "tekstolit" had a lower resistance to compression, and a higher resistance to 8 stretching, to static bending and to bending by blows. Lignofol is satisfactory in regard to water absorption, hardness and elec. resistance. W. R. Henn

The action of heat in the plasticization of wood materials. V. G. Matveev and N. M. Chetverikov. *Lesokhim. Prom.* **6**, No. 2, 19–25(1938); *Khim. Referat. Zhur.* **2**, No. 3, 121–2(1939).—Wood material is heated preliminarily to 60–80° (before pressing), then for 2 hrs. at 130°. The object of the preliminary heating is to obtain 9 the max. increase of the plasticity of the wood material. During the following heating the elastic forces (which were formed during the deformation) are dampened and a physicochem. transformation of the wood material takes place. Bricks of plasticized wood kept their shapes satisfactorily at a relative humidity of 60%. Pressed bricks, which had not been subjected to the second heating, were deformed at 60% relative humidity. Bricks which were heated to

100–10° swelled considerably at a humidity of above 60%. It is concluded that the 2nd heating decreases the hygroscopicity of the wood material. The wood material was darkened and its water resistance increased by a prolonged treatment at 120–40° after compression. W. R. Henn

Preparation of bakelitized wood material stable to acetic acid. E. N. Rassadina. *Lesokhim. Prom.* **6**, No. 2, 15-17(1938); *Khim. Referat. Zhur.* **2**, No. 3, 123 (1939).—Bakelitization of wood gave a product of good mech. and elec.-insulating properties and of high chem. stability. Four types of phenol-formaldehyde resins were investigated for the bakelitization. Best results were obtained from (1) basic soln. of resol resins (with NaOH as catalyst; the condensation did not reach the stage of sepn. into layers), (2) resinite prepd. from 6 parts of phenol, 7 parts of a 40% formalin soln. and 1% Na_2CO_3 soln. (by heating on a water bath at 80°; the water layer did not sep.). Birch wood material impregnated with these resins was boiled 30 hrs. in 15%, 60% and 80% AcOH soln., in black acid, in crude AcOH, in Et_2O and in MeOH. Changes in size and mech. properties of the samples and in color of the acid were noted. W. R. Henn

Formation of phenol-formaldehyde resin. I. Condensation of guaiacol with formaldehyde. Hans v. Euler, Erich Adler and Dagmar Friedmann. *Arkiv Kemi, Mineral. Geol.* **13B**, No. 12, 7 pp.(1939).—Guaiacol (I) (2.2 mol., 74.4 g.) was heated 10 min. on a water bath with 40% CH_2O soln. (1 mol.) and 0.024 mol. HCl. Distn. gave 30 g. of unchanged I, 9.75 g. of an oil, $b_{0.5}$ 210–12°, and higher fractions. The oil crystd. and was sepd. by crystn. from C_6H_{14} into *4,4'-dihydroxy-3,3'-dimethoxydiphenylmethane* (II), needles, m. 107–8° and *2,4'-dihydroxy-3,3'-dimethoxydiphenylmethane* (III), plates, m. 119–20°. I (1 mol.) with 40% CH_2O (2 mols.) and 10% NaOH (1 mol.) after 2 days at room temp. gave, when acidified and shaken with Et_2O, a cryst. ppt., probably a mixt. of vanillyl alc. and *1,5-di(hydroxymethyl)-2-hydroxy-3-methoxybenzene*. On standing, *3,3'-dimethoxy-4,4'-dihydroxy-5,5'-di(hydroxymethyl)diphenylmethane* (or an isomer) m. 148–9°, sepd. This was also formed from II (1 mol.), 2 mols. CH_2O, and 2 mols. NaOH in H_2O soln. by heating 1 day at 40–50°. III gave no cryst. product when similarly treated. Conclusion: The mechanism of the formation and hardening of I-CH_2O resins, involving the formation of $-CH_2-$ bridges, is similar to that for Ph-OH-CH_2O resins. Arnold M. Collins

High-grade coumarone (and indene) resins. W. Obst. *Tar & Bitumen* **37**, No. 13, 151–2(1939); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 377(1939).—A review. George Ayers

Microscopy in the resin industry. T. G. Rochow. *Ind. Eng. Chem., Anal. Ed.* **11**, 629–34(1939).—Use of the microscope in the detn. of *n*, sp. gr. and hardness and for the study of stresses, weathering of films, dispersion of pigments and reagents, and identification of fillers (by observation of polished cross sections). A. M. Collins

Resin bonding without hot presses. Thomas D. Perry. *Hardwood Record*, Special issue **1939**, 12, 16.—A discussion of the use of cold-setting resins for bonding operations. Leopold Scheflan

Furfural-phenol compounds. E. E. Novotny. *Modern Plastics* **16**, 32, 154–8(1938); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 377(1939).—The properties of furfural as a plasticizer and of furfural resins as hardening agents and components of synthetic resins are discussed. George Ayers

Note on the elastic properties of vinyl sheeting. S. Bateson. *J. Applied Phys.* 10, 887–9(1939).—Strips cut in the direction of extrusion were tested at 20, 30, 40 and 50°, at loads up to about 2.5 kg./sq. cm. Plastic flow apparently occurred at temps. above 40°. Creep is pronounced during both extension and recovery, obeying an empirical law of the form $S = S_0 + a_1 t^{1/3} + a_2 t$. Elongation and birefringence are not strictly proportional but exhibit considerable lag. Elasticity, creep and birefringence depend upon temp., amt. of plasticizer and viscosity of polymer. S. L. Gerhard

The physics of heat insulation. Alpheus W. Smith. *Verre et silicates ind.* **10**, 340–5(1939); cf. *C. A.* **33**, 4698³. Herbert S. Willson

New insulating material. L. Zubkova. *Legkaya Prom.* **17**, No. 4, 106–8(1938).—A new insulating material, Viamiz, is prepd. by foaming water solns. of tech. gelatin (6–10%), adding formalin and an antiseptic, pouring into wooden forms, and drying at 20–30°. The material burns but does not support combustion. It is hygroscopic and is insol. in alc. and benzene. Its use for soundproofing is suggested. B. Z. Kamich

The triple alliance in electrical insulation. Leo J. Berberich. *Elec. Eng.* **59**, 23–36(1940).—A review of progress in elec. insulation achieved by the combined efforts of physicists, chemists and elec. engineers. 30 references. C. G. F.

The thermal insulation of carbide shaft ovens. N. N. Znamenskiĭ. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 56–7 (1939).—When vermiculite, a hydrated Mg Al silicate contg. Fe, Na and sometimes K, is heated to 500° it loses H_2O and swells to 15–20 times its original vol., forming zonolite. The latter is an excellent insulating material. H. M. Leicester

New noninflammable insulating liquid for transformers. K. A. Andrianov and A. K. Vardenburg. *Vestnik Elektroprom.* **10**, No. 5, 14–17(1939).—A new noninflammable insulating liquid for transformers includes trichlorobenzene and Sovol (chiefly pentachlorobiphenyl) and has the following properties: colorless, $d_4^{20} = 1.506$–1.550, at 65° not over 10 centipoises, at 90° about 4 centipoises, b. p. 310–320°, coeff. of expansion 0.0006, heat capacity 0.25 cal./kg.°C., heat cond. about 0.2 cal./m.°C. hr., solidifying point 29–30°, acid no. 0.01–0.05, dielec. permeability 4.5 at 20° and 3.8 at 90°, tangent of angle of dielec. losses was 0.001–0.002 at 20° and 0.01–0.05 at 90°. The elec. resistance of the liquid was decreased after being heated at 110° for 31 days with various materials, such as magnesia cement, bakelite, enameled iron, which are used in transformer construction. B. Z. Kamich

Insulation finishes. E. E. Halls. *Paint Manuf.* **9**, 299–305, 309(1939).—Practical information is condensed and actual results are given. Finishes may be considered under the following headings: (1) media for coil treatments, (2) finishes for synthetic plastics, both laminated and molded, (3) ebonite lacquers, (4) insulating finishes on metalwork, (5) finishes on ceramic components and (6) application of shellac. The 1st 3 headings are discussed. *Ibid.* 359–60.—The latter 3 headings are discussed. Resistors having porcelain or ceramic spools or cores, and slate panels are detd. by the working temps., etc. For resistors which operate at 100° low-bake black enamels having phenol-aldehyde oil-sol. resin base are employed. Lab. characteristics of such enamels are given. Shellac-base media are used for brushing over enamel wire windings of coils. W. H. Boynton

Method for preparing rubber (without the use of gasoline) applied to the preparation of artificial leather. A. S. Aizenshtein. *Kozhevenno-Obuvnaya Prom. U. S. S. R.* **18**, No. 2, 39–40(1939); *Chem. Zentr.* **1939, II**, 3229–30.—Rubber is rolled alone at a spacing of the rollers of 1.5 mm. and then with the admixt. of S and half of the required amt. of softeners (rubberax, rosin, pine oil, coal-tar oil and cumarone oil, divinol) with half of the required amt. of leather tissue and carbon black; the procedure is repeated in the same order with the remaining admixtures. Each individual operation lasts 3 min. and the initial temp. must not exceed 25–30°, while the rolling temp. may be raised to 45° after the introduction of the ingredients. The mixt. is cooled after the introduction of ZnO and is rolled for 2–3 min. with a roller spacing of 4 mm.; then the accelerators (captax, thiuram), are added, and the mass is cooled, formed on plates to a thickness of 7.5 mm. and pressed to a thickness of 5.5 mm., subjected to a pressure of 45 kg. per sq. cm. and finally vulcanized. The following proportions of ingredients are recommended: 32–3% rubber, 13–17% divinol and 27–30% softeners (preferably coal-tar oil or cumarone oil). A. A. Boehtlingk

Nonmetallic acid-resisting materials. K. A. Polyakov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 29-32(1939). H. M. Leicester

Adhesion in plywood. E. C. M. Ernest and C. B. Pettifor. *Wood* **4**, 65-6(1939).—The animal glue, casein glue and blood-albumin glue tested are unsuitable for use in plywood exposed to warm humid conditions, the first two because of their lack of resistance to moisture as such, and the third because of weakening brought about by the action of microörganisms, for the growth of which such conditions are ideal. Synthetic-resin glue is resistant to both moisture and microörganisms. Certain com. grades of glues of the nonsynthetic types may contain special ingredients that render them immune from the harmful effect mentioned. Leopold Scheflan

Fumigation with hydrocyanic acid gas. M. C. Mossop. *Rhodesia Agr. J.* **36**, 220-35, 317-29(1939).—A review with detailed instructions for producing and using HCN gas. Colin W. Whittaker

Control of dermestids and clothes moths. N. L. Fremed. *Pests* **7**, No. 12, 13-14(1939).—Approx. a dozen cases of larder- and hide-beetle infestations were reported out of 4000 establishments in New York City during the last year. The increasing use of hair felt and other susceptible materials for sound proofing and insulation is responsible for increasing trouble with clothes moths and carpet beetles. In New York City where HCN fumigation is prohibited in most cases, F. used ethylene dichloride-CCl_4 mixts. as a fumigant for insulating materials infested with clothes moth and in addn. he sprayed with pyrethrum ext. and aliphatic SCN compds. in soln. in a petroleum distillate. Details of a com. control case are given. Henry H. Richardson

Plasticized compositions containing γ-polyvinyl chloride and suitable for pipe linings, etc. Claude H. Alexander (to B. F. Goodrich Co.). U. S. 2,175,048, Oct. 3. Gamma polyvinyl chloride is used with bisethyl-*o*-phenylene disulfide or other compd. of the general formula $SA_1(R_1).S.A_2R_2$, wherein R_1 and R_2 represent a member of the class consisting of aliphatic and alicyclic hydrocarbon groups contg. 2-6 C atoms, and A_1 and A_2 represent aromatic hydrocarbon nuclei with the sulfur linkage in the ortho position.

Polycarboxylic acid esters. Russell McGill (to E. I. du Pont de Nemours & Co.). U. S. 2,172,803, Sept. 12. *Solvents, plasticizers, resin intermediates, alc. denaturants* and *"pesticidal" esters* such as 3-methyl-3-hydroxy-2-butanone adipate, m. 58-9°, are prepd. by treating, in the presence of a Hg salt of a carboxylic acid such as $Hg(OAc)_2$, an acid having an ionization constant of less than 0.0007 with an alkynylcarbinol wherein the carbinol group is joined to an acetylenic C, as by treating adipic, succinic, glutaric, hexahydrophthalic, suberic, sebacic, mucic, malic, or tricarballylic acid with dimethylethynylcarbinol, propargyl alc., methylpropargyl alc., ethylpropargyl alc., hexylpropargyl alc., methylethynylcarbinol, ethylethynylcarbinol, ethylhexynylcarbinol, isopropylethynylcarbinol, hexylethynylcarbinol, vinylethynylcarbinol, chloromethylethynylcarbinol, methylethylethynylcarbinol, methylpropylethynylcarbinol, diethylethynylcarbinol, methylisobutylethynylcarbinol, methylamylethynylcarbinol, diisopropylethynylcarbinol, 1-ethynylcyclohexanol, methylphenylethynylcarbinol, isopropylphenylethynylcarbinol, diethylphenylethynylcarbinol, dimethylpropynylcarbinol, methylpropylbutynylcarbinol or butylamylethynylcarbinol.

Methallyl ethers of phenylphenols. Gerald H. Coleman and Garnett V. Moore (to Dow Chemical Co.). U. S. 2,170,990, Aug. 29. By treating 2-methallyl chloride with a phenylphenol in the presence of an alkali (suitably in acetone at its reflux temp.), products are obtained such as the 2-methallyl ether of 2-phenylphenol, b_3 140-2°, the 2-methallyl ether of 3-phenylphenol, b_4 160-1°, the 2-methallyl ether of 4-phenylphenol, m. 75.5-6.0°, the 2-methallyl ether of 4-chloro-2-phenylphenol, b_5 138-40°, the 2-methallyl ether of 4-*tert*-butyl-2-phenylphenol, b_3 152-3°, and 2-methallyl ethers of 2,4-dichloro-6-phenylphenol, 4-bromo-2-phenylphenol, 2-chloro-4-*tert*-butyl-6-phenylphenol, 4-iodo-2-phenylphenol, 2'-chloro-4-phenylphenol, 2',2,6-trichloro-4-phenylphenol, 4'-bromo-2-methyl-4-phenylphenol, 4'-isopropyl-4-phenylphenol, 4-*sec*-butyl-2-phenylphenol, 4-cyclohexyl-2-phenylphenol, 2,6-dimethyl-3-phenylphenol. These ethers may be used as *plasticizers* and modifying agents in polymerized vinylidene chloride compns.

Alkylhalodiphenyl oxides. Gerald H. Coleman and Robert R. Dreisbach (to Dow Chemical Co.). U. S. 2,170,989, Aug. 29. Alkylhalodiphenyl oxides which vary from oily liquids to resinous solids at room temp. and are suitable *for use as dielectrics in condensers, transformers*, etc., and as *plasticizers in resin* and *varnish compns.*, etc. are prepd. by halogenating and alkylating diphenyl oxide. Details are given of the production of: ethylchlorodiphenyl oxide, b_6 155-64°; diethylchlorodiphenyl oxide, b_6 170-4°; a mixt. of polyethylchlorodiphenyl oxides, b_6 200-210°; a mixt. of ethylchloro- and ethyldichloro-diphenyl oxides, b_5 140-65°; ethyltrichlorodiphenyl oxide, b_5 165°; a mixt. of ethyltetrachloro- and ethylpentachlorodiphenyl oxides, b_3 190-210°; isopropylchlorodiphenyl oxide, b_6 156-69°; diisopropylchlorodiphenyl oxide, b_6 181-4°; *tert*-butylchlorodiphenyl oxide, b_6 173-6°; di-*tert*-butylchlorodiphenyl oxide, b_5 192-5°; an isomeric di-*tert*-butylchlorodiphenyl oxide, b_6 198-201°; *sec*-butyldichlorodiphenyl oxide, b_6 175-80°; di-*sec*-butyldichlorodiphenyl oxide, b_5 205-8°; isopropyltetrachlorodiphenyl oxide, b_2 199-202°; and an isomeric isopropyltetrachlorodiphenyl oxide, b_2 202-207°.

Ethylene glycol aryloxyacetates. Ernest F. Grether, William R. Shawver and Russell B. Du Vall (to Dow Chemical Co.). U. S. 2,170,995, Aug. 29. Ethylene glycol aryloxyacetates of the general formula $XOCH_2CH_2OOCCH_2OR$, where R represents an aryl group and X represents H or an aryloxyacetyl radical, are prepd. by heating a mixt. of an aryloxyacetic acid and ethylene glycol, at a pressure not greatly above atm. pressure, to a reacting temp. (suitably up to about 140-175°), and recovering the product as by fractional distn., crystn., etc. A catalyst may be used such as $NaHSO_4$, H_2SO_4 or benzenesulfonic acid. The products may be used as *plasticizers for cellulose ethers or esters* and *synthetic resins*. Details are given of the production of the following esters of ethylene glycol: bis(phenoxyacetate), m. 92°; bis(2-chlorophenoxyacetate), m. 107°; bis(2-phenylphenoxyacetate), a viscous liquid; bis(4-*tert*-butylphenoxyacetate), m. 77°; a mixed ester of 2-chlorophenoxyacetic acid and phenoxyacetic acid, $b_{0.5}$ 265-75°; mono(phenoxyacetate), b_{10} about 175°; and mono(phenoxyacetate) mono(2-naphthoxyacetate), m. 115°. U. S. 2,170,996 gives details of the production of the following esters of ethylene glycol: bis(2-methylphenoxyacetate), m. 57°; bis(3-methylphenoxyacetate), m. approx. 74°; bis(4-methylphenoxyacetate), m. 56°; bis(2-chloro-4-methylphenoxyacetate), m. 74°; bis(2-phenylphenoxyacetate), a viscous liquid; and bis(4-*tert*-butylphenoxyacetate), m. approx. 77°; and general mention is made of the like production of various similar compds. Cf. *C. A.* **33**, 3024⁸.

Extruded or molded articles of polyvinyl alcohol com-

positions. Ernst Schnabel (to Resistoflex Corp.). U. S. 2,177,612, Oct. 24. App. is described, and a process of producing an intermediate product for use in charging an extruder or mold in forming articles which have a basis of polyvinyl alc. contg. a predetd. amt. of solvent such as water, which involves uniformly distributing throughout a mass of finely divided dry polyvinyl alc. such an amt. of volatile solvent for the alc. as will be absorbed into the particles without substantially affecting their aggregate state but in excess of that desired in the final product and sufficient to result in cohesion of the particles during the rolling step, and thereafter pressing the moistened material between closely set rolls in one or more single passes therethrough at a solvent-expelling temp. below 100° to form a thin coherent strip and to remove excess solvent before extrusion or molding.

Water-soluble condensation products such as those from phenols and formaldehyde. Hermann Noerr and Gustav Mauthe (to I. G. Farbenind. A.-G.). U. S. 2,177,420, Oct. 24. A process for prepg. water-sol. condensation products comprises sulfonating a fusible condensation product derived from a phenol and an agent capable of linking aromatic nuclei selected from the class consisting of acetaldehyde, chloroacetone, dichloro ether, CH_2O and substances yielding CH_2O, while introducing at the most, one sulfonic acid group into the condensation product per every two aromatic nuclei contained therein, and without rendering the condensation product completely water-sol. thereby, and then treating the sulfonated product with a further quantity of the agent until it is completely water-sol.

Synthetic resins. Clarence Bremer (to Atlas Powder Co.). U. S. 2,176,415, Oct. 17. A process of making an odorless, tasteless resinous material suitable for coating food wrappers, etc., involves heating a mixt. consisting essentially of an inner ether derivable from a straight chain hexahydric alc., such as sorbitol or mannitol with abietic acid or a rosin from grades WG to X, and a hydroxyl-free, aliphatic dibasic acid in which the carboxyl groups are sepd. by at least 2 C atoms, such as maleic, adipic or succinic acid at temps. (suitably to 295°) to effect desired reaction with caramelization of the product while substantially excluding air and removing volatile odor- and taste-producing reaction products from the reaction mixt., the total no. of acid equivs. in the reaction mixt. being about 2.8 to 4.5 per mol. of inner ether, and the dibasic acid mol. fraction of the total acid present being substantially from 0.05 to 0.35.

Polyvinyl resins. Geo. O. Morrison and Aubrey F. Price (to Shawinigan Chemicals Ltd.). U. S. 2,176,859, Oct. 17. A method of making a polyvinyl resin involves treating a hydrolysis product of a polyvinyl ester other than polyvinyl formate, such as polyvinyl acetate, with a material (such as formaldehyde) contg. an active carbonyl group capable of combining with the hydroxyl groups of the hydrolysis product, in the presence of a catalyst such as H_2SO_4 and a lower satd. aliphatic acid such as HOAc in which the hydrolysis product is initially dissolved. The resulting product may be used in making lacquers or molded products. Various examples are given.

Phenol-butyraldehyde resin. Wm. J. Bannister (to Resinox Corp.). U. S. 2,176,951, Oct. 24. A product which is suitable for use in coatings, etc., is produced by treating, in the presence of an alk. catalyst such as NaOH (and suitably by refluxing in N), a mixt. of butyraldehyde and a phenol, until there is formed a resinous condensation product lighter in color than one similarly produced in the presence of an acid catalyst.

Noncrystallizing resin suitable for use in adhesives, core oils, soaps, sizings, etc. Samuel Palkin and Wiley C. Smith (to the people for free use). U. S. 2,176,660, Oct. 17. A noncrystg. resin is produced by a method which involves permitting normal pine oleoresin to undergo substantially max. crystn., then filtering out the crystals, recovering the filtrate, and removing volatile oils from it, as by steam distn.

Sulfonates of polyaryl polyethers (wetting, emulsifying, cleansing and introfying agents for textile treatments). Herman A. Bruson (to Röhm & Haas Co.). U. S. 2,171,498, Aug. 29. Numerous details and examples are given of the production of sulfonates of the general formula ROAOR′ in which R and R′ are each aromatic groups at least one of which contains a nuclear substituent of the group consisting of hydrocarbon and acyl groups of more than 3 C atoms and A is an alkylene group or polyalkylene ether group in which at least 2 C atoms sep. successive ether atoms. Among the compds. obtained are: a disulfonate of bis-β-(*p*-α,α,γ,γ-tetramethylbutylphenoxy)-ethyl ether, a water-sol. sulfonate of β-laurylphenoxyethyl β′-phenoxyethoxyethyl ether, and a water-sol. sulfonate of β-*p*-*tert*-butylphenoxyethoxyethyl β′-*p*-*tert*-butylphenoxyethyl ether.

Amines and derived quaternary ammonium bases and salts. Herman A. Bruson (to Röhm & Haas Co.). U. S. 2,170,111, Aug. 22. Amines, various water-sol. bases and salts of which may be used as *wetting, emulsifying, dispersing* and *cleaning agents* and which have the general formula R—O—A—(O—A)$_n$—O—A—N-≡ in which R is a hydrocarbon radical contg. an aromatic nucleus at its point of attachment to the ether O atom, A is an alkylene radical having more than one C atom, *n* is one or zero, and N is the N atom derived from NH_3, a primary or secondary aliphatic, cycloaliphatic, aryl aliphatic or hydroxy aliphatic amine or secondary heterocyclic amine, are prepd. by condensing one mol. each of a monohydric phenol and a polyalkylene ether, having a halogen substituent on each of its terminal C atoms, in the presence of an alk. condensing agent, treating the product thus obtained with NH_3, a primary or a secondary amine and treating the resulting amine hydrohalide with an alkali or alk. earth hydroxide. Numerous examples are given, including the production of: [*p*-(α,α,γ,γ - tetramethylbutyl)phenoxyethoxyethyl]diethanolamine, b_5 255–260°; [*N*-*p*-(α,α,γ,γ-tetramethylbutyl)-phenoxyethoxyethyl]morpholine, b_4 203–8°; [*p*-(α,α,γ,γ-tetramethylbutyl)phenoxyethoxyethyl] - *N* - benzylpiperidinium chloride (suitable for use as a spreader for insecticides); (*p*-*tert*-butylphenoxyethoxyethyl)diethanolamine, b_{10} 265°; (*p*-*tert*-amylphenoxyethoxyethyl)diethanolamine, b_4 240–5°; (*p*-*tert*-amylphenoxyethoxyethyl)bis(hydroxyethyl)ethylammonium ethylsulfate (a pale-yellow oil suitable for wetting-out cotton yarn); (*p*-*tert*-amylphenoxyethoxyethyl)dimethylamine; *tert*-octylphenoxyisopropoxyisopropyl chloride, b_5 190–5°; (thymoxyethoxyethyl)diethanolamine, b_5 233–6°; β-(*tert*-octylphenoxyethoxy)ethyl β′-chloroethyl ether, b_3 199–207°; (β-naphthoxyethoxyethyl)diethanolamine, b_7 275–80°; (*o*-benzylphenoxyethoxyethyl)diethanolamine, b_6 280 85°; (*o*-cyclohexylphenoxyethoxyethyl)diethanolamine, b_6 262°; (*p*-cyclohexylphenoxyethoxyethyl)diethanolamine, b_8 280–85°; (*o*-phenylphenoxyethoxyethyl)diethanolamine, b_{10} 275–80°; (*p*-phenylphenoxyethoxyethyl)diethanolamine (a resinous mass); and (*p*-*tert*-octylphenoxyethoxyethyl)-*N*-dibenzylamine (waxy crystals), and some related products.

Reaction products of pyrophosphoric acid with acyl derivatives of aliphatic polyhydroxy substances (wetting, penetrating, detergent, emulsifying and ore-separating agents, etc.). Benjamin R. Harris. U. S. 2,177,650, Oct. 31. Numerous examples are given such as the production of reaction products of pyrophosphoric acid with polyhydroxy substances, where at least one hydroxyl group of the polyhydroxy substance has its H substituted by a lipophile group. The lipophile group may include any org. acid group, particularly fatty acid groups having preferably at least 4 C atoms; or the lipophile group may be an alkyl radical derived from an alc. Specific examples of polyhydroxy substances, the residues of which may serve as linkages between the lipophile groups and the hydrophile pyrophosphoric acid groups, include: mucic acid, tartaric acid, saccharic acid, gluconic acid, glucuronic acid, gulonic acid, mannonic acid, trihydroxyglutaric acid, glyceric acid, carboxylic oxidation products of polyglycerols and sugars, and sugar alcs. The polyglycerols and their oxidation products are produced by polymerizing glycerol, preferably by heating with about 1% of alkali at 250–60° for about 3 hrs. in the presence of an inert gas (forming a mixt. of

various polyglycerols which may then be oxidized with mild oxidizing agents to convert at least one of the primary hydroxy groups to a carboxylic group).

Capillary-active compounds. I. G. Farbenindustrie A.-G. Brit. 508,066, June 21, 1939. These are made by causing CH_2O or a polymer thereof to act in the presence of a tertiary base and an anhydride of an org. dicarboxylic acid upon a compd. that contains a hydrocarbon radical having at least 10 C atoms and at least once 1 of the groupings —CON< or —CSN< in which at least 1 exchangeable H atom is present at the N atom. In a modification, the Me compd. obtained by causing CH_2O or a polymer thereof to react with a compd. contg. these groupings is caused to react with a tertiary base and an org. carboxylic acid anhydride. The products may be used, in conjunction or not with soaps, Turkey-red oil, H_2SO_4 esters of alcs. of high mol. wt., the condensation products of fatty acids with amino carboxylic or amino sulfonic acids, glue, gums and org. solvents, as *wetting, emulsifying* and *washing agents;* and by impregnation therewith at 80–100° natural or artificial textile fibers of vegetable or animal origin may be *rendered H_2O-repellent* or *waterproof.* Among examples, the following compds. are heated with paraformaldehyde (I) at 80–100° for 0.5–6 hrs.: (1) stearamide (II), phthalic anhydride (III) and pyridine (IV), (2) octadecylurea, diglycolic anhyride V and β-dimethylaminoethyl methyl ether, (3) Et octadecylcarbamate, IV and V. Among further examples a worsted yarn fabric is treated with an aq. soln. contg. the product of reaction of I, II, *N*-tetramethylmethylenediamine and III, centrifuged, dried at 50° and then heated at 100–110° for 1 hr.

Esters of **sulfo dicarboxylic acids.** Alphons O. Jaeger (to American Cyanamid & Chemical Corp.). U. S. 2,176,123, Oct. 17. *Wetting, detergent* and *emulsifying agents* comprise esters of the general formula $R(CO_2X)(CO_2E)$, in which R is an aliphatic carbon chain substituted by a sulfonic acid group and another substituent selected from the group consisting of hydrocarbon, alkoxy, hydroxyl, halogen and nitro groups directly linked thereto, X is a positive ester-forming radical contg. at least 5 C atoms and E is a member of a group consisting of hydrogen, a salt-forming radical, and a positive, ester-forming radical. Numerous uses of such products are given, with details of the production of: an alkali metal salt of dimethyl sulfomaleate; diamyl sulfosuccinate; the Na salt of dioctyl sulfosuccinate; the Na salt of dilauryl sulfosuccinate, dicapryl Na sulfosuccinate; difenchyl Na sulfosuccinate; Na diethoxyethyl sulfopyrotartrate; the Na salt of dibutoxydiethylene glycol sulfosuccinate; the cyclohexyl ester of sulfoglutaric acid; the Na salt of dibenzyl sulfoadipate; Na diphenyl sulfopyrotartrate; the Na salt of the ditetrahydrofurfuryl ester of sulfosuccinic acid; the diester of Na sulfosuberic acid with methylisobutylcarbinol; dibutyl Na sulfosebacate; the Na salt of distearyl sulfosuccinate; the Na salt of dioleyl sulfosuccinate; the Na salt of ethyl stearyl sulfosuccinate; the Na salt of glycol sulfosuccinate; the di-Na salt of octyl sulfosuccinate; the Na salt of glycerol sulfosuccinate; the Na salt of diglycol sulfosuccinate; the Na salt of the glycerol ester of sulfosuccinic and acetic acids; a glycerol ester of sulfosuccinic acid and acid amyl phthalate; a glyceryl phthalate sulfosuccinate; mono-Na sulfobutylsuccinic acid; the Na salt of dihexyl sulfobutylsuccinate; diamyl Na sulfobromosuccinate; bis(ethylbutyl) Na sulfobenzylsuccinate; the di-Na salt of disulfosuccinic acid ethyl ester; and some related compds.

Carboxylic acid esters of aromatic sulfo carboxylic acids with hydroxyalkylamides. Otto Albrecht (to Soc. pour l'Ind chim. à Bâle). U. S. 2,169,515, Aug. 15. Carboxylic acid esters of aromatic sulfo carboxylic acids of the benzene series are produced by treating an aromatic sulfo carboxylic acid or an ester, anhydride, salt or halide of such an acid with a hydroxyalkylamide of carboxylic acids contg. at least 8 C atoms and difficultly sol. in water, the products being suitable for use as *wetting, cleansing, dispersing, equalizing, softening or foaming agents.* As parent materials, there may be used for example sulfoacetic acid, sulfobutyric acid; sulfosuccinic acid, sulfonaphthenic acids, sulfobenzoic acid, sulfosalicylic acid, the sulfonic acids of phthalic acid, isophthalic acid or naphthalic acid or their anhydrides, phthalic acid disulfonic acid, sulfoterephthalic acid and sulfo-4-chlorophthalic acid. The *N*-hydroxyalkylamides used for esterifying one of the carboxyl groups may be derived from aliphatic monohydroxyamines or polyhydroxyamines, such as ethanolamine, diethanolamine or glucamine which are acylated with aliphatic or cycloaliphatic carboxylic acids, for example naphthenic acids, and still contain at least one free hydroxyl group. Such products are, for example, *N*-hydroxyethylundecylenamide, *N*-hydroxyethyllauramide, *N*-hydroxyethylpalmitamide, stearic acid glucamide, *N,N*-dihydroxydiethyllauramide and *N*-dihydroxypropyllauramide. For neutralizing the second carboxyl group of sulfodicarboxylic acid monoesters there may be used an oxide, hydroxide or carbonate of a univalent or a multivalent metal, especially of an alkali metal, or an org. base such as cyclohexylamine or triethanolamine. The sulfonic acid group linked to a hydrocarbon residue which in some cases may be substituted may be present in the form of a salt of a uni- or a multivalent metal. It may also be neutralized with ammonia or with an amine before or after the conversion of one or both carboxyl groups.

Aminoaryl sulfones. J. R. Geigy A.-G. Brit. 508,148, June 27, 1939. These are prepd. by causing sulfones with halogen in the *o*- or *p*-position to the SO_2 group and of formula halogen—$C_6H_4SO_2CHRR'$, where R is H or a satd. or an unsatd., substituted or unsubstituted aliphatic or alicyclic residue, which may be interrupted by hetero atoms and R′ is H, alkyl or -COX, where X is alkyl, aryl, OH, alkoxy, NH_2 or mono- or di-alkylamino, and where at least 1 of R and R′ contains a residue of at least 8 C atoms, to react, preferably in the presence of Cu as a catalyst, with NH_3, primary aliphatic, araliphatic and hydroaromatic amines or secondary aliphatic, aliphatic-araliphatic, aliphatic-hydroaromatic or heterocyclic amines, e. g., NH_2Me, NH_2Bu, benzylamine, cyclohexylamine, $NHMe_2$, $NHBu_2$, $NHAm_2$, methylbenzylamine, methylcyclohexylamine, piperidine. The products may be further alkylated or may be converted into salts of org. or inorg. acids. For examples see *C. A.* **33**, 8859[4], 9675[1].

Polymerizing iso and normal butenes. Edwin F. Nelson (to Universal Oil Products Co.). U. S. 2,176,354, Oct. 17. App. is described, and a process for the mixed polymerization of iso and normal butenes which comprises subjecting a mixt. contg. iso and normal butenes to the action of a solid phosphoric acid catalyst at a polymerizing temp. above 135° under conditions of time and super-atm. pressure sufficient to effect substantial interpolymerization of the iso and normal butenes, and controlling the polymerizing temp. to prevent it from increasing to a point above 163° as a result of the exothermicity of the reaction by regulating the butene content of the mixt. to approx. 10–20%.

Cleaning mica and similar materials. Francis C. Atwood (to Atlantic Research Associates, Inc.). U. S. 2,177,358, Oct. 24. App. is described, and a method of treating mica and similar laminated material to remove dirt and other foreign impurities by passing the material between relatively smooth pins or the like moving relative to each other at such a speed and so spaced as to engage the laminae at spaced points and produce essentially a snapping and flexing of the laminae accompanied by a grinding of the larger particles of the impurities from the laminae.

Wax compositions suitable for floor polishes, etc. Homer C. Brumbaugh (to Universal Chemical Corp.). U. S. 2,177,240, Oct. 24. An aq. emulsion of a wax such as yellow carnauba wax is formed, by using, as an emulsifying agent, a morpholine compd. with a fat acid of high mol. wt. such as oleic acid, holding the wax dispersed in such small particle size that it will dry bright or with substantial luster when merely applied to a surface and exposed to the atm. without rubbing (the emulsifying agent being decomposable by drying of the compn. so that the compn. loses its ability to re-emulsify with water).

Polystyrene compositions suitable for coatings. Sylvia M. Stoesser and Arnold R. Gabel (to Dow Chemical Co.).

U. S. 2,174,538, Oct. 3. Polystyrene is plasticized with the salicylate of diethylene glycol monoethyl ether or with other salicylate of the general formula $o\text{-}R'OC_6H_4COO(C_nH_{2n})_mYOR''$, where R' is H or an alkyl radical, R'' is a radical selected from the group consisting of an alkyl or alkoxyalkyl radical, Y is a carbonyl or methylene radical, and *m* and *n* are integers, to decrease the permeability and increase the adhesiveness. Cf. *C. A.* **33**, 8862[2]. 1

Adhesive sheeting suitable for sealing wrappers of lustrous cellulose, etc. Richard G. Drew (to Minnesota Mining & Mfg. Co.). U. S. 2,177,627, Oct. 31. A transparent flexible nonfibrous cellulose film backing is used with a nonoffsetting, normally tacky and pressure-sensitive water-insol. adhesive coating such as one of a rubber-resin mixt. contg. a reinforcing and coloring pigment such as ZnO, firmly united to and visible through the backing, the back surface of the backing being lustrous and inactive to the adhesive coating so as to permit winding, unwinding and rewinding of the material without substantial offsetting of adhesive. 2 3

Moistureproof coated sheets of material such as wrapping tissue. Robert B. Flint and James A. Mitchell (to E. I. du Pont de Nemours & Co.). U. S. 2,177,645, Oct. 31. A thin, flexible, slippery, nonfibrous, transparent sheet such as one with a base of regenerated cellulose is provided with a moisture-proofing coating contg. a film-forming ingredient such as a cellulose ester or ether, a moistureproofing agent such as paraffin wax, and, as a "slip agent" in a phase sep. from the main body of the coating, Zn acetylacetone or other solvent-sol. beta-diketone of the formula Q-CO-CH_2-CO-R, in which Q and R represent alkyl or alkoxy groups and which has a metal substituted for enolic H, such compd. having a soly. of at least 1% in toluene at a temp. of 25° and 0.5 g. of the compd. being at least partially insol. in 25 cc. acetone at 25° (the compd. being present in insufficient quantity substantially to impair the transparency of the sheet). Various examples are given. 4

Forming sheeting of thermoplastic material such as cellulose esters and ethers. Ernest C. Blackard (to Eastman Kodak Co.). U. S. 2,177,633, Oct. 31. Various structural and operative details are described of an app. in which material is forced through a die to form an extruded sheet which is supported, adjacent to the die orifice, by jets of compressed gas such as air. 5

Forming sheets of thermoplastic material such as plasticized gamma polyvinyl chloride. Waldo L. Semon (to B. F. Goodrich Co.). U. S. 2,176,153, Oct. 17. To produce a sheet substantially free from grain, a thermoplastic material is calendered and is floated across the surface of a liquid such as Hg which does not have a destructive effect on the material and which is heated to a temp. at which the material is plastic, suitably about 150°. 6 7

Extrusion of thermoplastic materials such as cellulose acetate, as in the manufacture of sheets. John S. Kimble and Ernest C. Blackard (to Eastman Kodak Co.). U. S. 2,177,658, Oct. 31. App. is described, and a method of extruding a continuous attenuated article of uniform d. and dimensions from an extrusion die which involves regularly injecting predetd. uniform amts. of a suitable volatile-solvent-free cellulose deriv. compn. from a pressure cylinder into a screw conveyor at least a portion of the input end of which is cooled, conveying the compn. from the cooled conveyor to a heated screw conveyor in which the compn. becomes plastic, and forcing the plastic compn. through a suitable die attached to the heated conveyor. 8

Sheeting such as that of cellulose acetate compositions. John S. Kimble, Ernest C. Blackard and John S. McLellan (to Eastman Kodak Co.). U. S. 2,177,660, Oct. 31. App. is described, and a process which involves producing a low-shrinking thermoplastic sheet by forcing a material such as a cellulose acetate compn. through an extrusion die at a const. rate and pressure, supporting the sheet near the die by a gas such as air or N, and passing the sheet through a heater while supporting and conveying it in a manner and at a rate not imposing any substantial tension upon the sheet, so that residual strains are substantially removed. U. S. 2,177,661 (John S. Kimble, sole inventor; to same assignee) relates to app. and to a continuous method of improving the phys. characteristics of thermoplastic sheeting which comprises heating the sheet, to an extent which will permit residual strains therein to equalize, in a heated conditioning chamber while supporting the sheet without substantial tension thereon, then reducing the thickness of the sheet by passing it through a calender, further heating the sheet, further reducing the thickness of the sheet by a final calendering operation, then conducting the sheet through a final heated conditioning chamber maintained at a temp. of 50–75° while supporting the sheet without substantial tension thereon whereby strains in the sheet normally releasable at room temps. are released, and cooling the sheet while under substantially no tension.

Removing paint and varnish films. Gilbert F. Hoffmann (to Pittsburgh Plate Glass Co.). U. S. 2,176,995, Oct. 24. A soln. of AcCl in Me Et ketone is applied to the coated surface and the AcCl is subsequently neutralized with a soda soln.

Products such as bristles, from synthetic polyamides. Donald D. Coffman (to E. I. du Pont de Nemours & Co.). U. S. 2,177,637, Oct. 31. For improving the resiliency and stability of articles such as fibers or films made from fiber-forming synthetic polyamides such as polyhexamethylene adipamide, the articles are treated (suitably in a dil. aq. soln. also contg. NH_4Cl) with CH_2O or a CH_2O-liberating material. Various details and modifications of treatment are described.

Extruded articles such as lead cable sheaths. Harvey A. Anderson (to Western Elec. Co.). U. S. 2,177,681, Oct. 31. Various details of app. and operation.

Forming tubes comprising cement and asbestos. John Ferla and Levi H. Blouch. U. S. 2,177,643, Oct. 31 Various details of app. and operation for applying superposed layers of material on a mandrel.

Treated paper containers for food products, etc. Melvin Wagner (to Liquid Carbonic Corp.). U. S. 2,176,370, Oct. 17. A method of forming a container, substantially impervious to gases and liquids, involves: (*a*) coating a sheet of paper with a solvent-contg. impervious varnish; (*b*) applying thereon a preformed thermoplastic medium in its cold state; (*c*) folding the sheet into container form with the thermoplastic medium adjacent to the edges of the sheet in engagement with one another; and (*d*) applying heat and pressure to the sheet to cause the thermoplastic media to adhere to one another to seal the container. Rubber hydrochlorides such as "Pliofilm" or a vinyl resin may be used as the thermoplastic material.

Rodent poisons. Paul Herzig and Hans Kükenthal (to Winthrop Chemical Co.). U. S. 2,177,598, Oct. 24. A water-sol. cellulose deriv. such as methylcellulose or a hydroxyethylated cellulose is used as a carrier for poisons to be eaten by rodents.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

The division of water, sewage and sanitation chemistry. Edward Bartow. *Ind. Eng. Chem., News Ed.* **17**, 776 (1939).—Historical and descriptive. E. J. C.

The mineral waters of Boario (Brescia). Giuseppe Bragagnolo. *Ann. chim. applicata* **29**, 402–13 (1939).—These waters are of medium mineral content, consisting essentially of alk. earth sulfates. These waters have definite diuretic, digestive, antiuric acid and anticatarrhal *medicinal value;* they are of value in diseases due to low metabolic rate. These waters have been famous from

early times under the names: Igea, Eximia and Silia waters. A. W. Contieri

Purification of the waters from peat-gas generators. V. T. Ruff and O. I. Martynova. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 10, 74–84; *Khim. Referat. Zhur.* **2**, No. 3, 102–3(1939).—In order to purify the waste waters of the peat-gas plants several schemes are proposed for the utilization of the most valuable admixts., i. e., fatty acids (up to 60 kg./cu. m.), phenols (up to 6 kg./cu. m.) and NH_3 (up to 18 kg./cu. m.). The water (which is purified from tar) is limed and evapd. to recover fatty acids as their Ca salts. The condensed vapor of the stills is passed through a layer of activated charcoal, then into an NH_3 column, where a concd. NH_3 soln. is obtained by blowing with steam. The purified water is clear (over 30 cm.), pH = 7.0–7.5; it contains phenol 1 mg./l., fatty acids traces; NH_3 up to 20 mg./l., O consumption 10 mg./l. The activated charcoal is regenerated with hot C_6H_6 followed by blowing with superheated steam. W. R. Henn

Purification of phenol waste waters by activated carbon and the regeneration of the carbon with dichloroethane. A. I. Kozko. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 11, 86–92; *Khim. Referat. Zhur.* **2**, No. 3, 103(1939).—The tarry water was settled, passed through König and coke filters, made alk., passed into dephenolizing adsorbers at normal temp. at a velocity of 2.0–3.5 m./hr. through a layer of C not less than 1.0 m. thick, chlorinated, neutralized with chalk and lime and filtered. The water thus treated conformed to all sanitary requirements. Dichloroethane is superior in all respects to C_6H_6 and gasoline as an extg. agent. The activated C and the impure dichloroethane are regenerated very simply and completely. W. R. H.

Fundamentals of water pretreatment. Frank Bachmann. *J. Am. Water Works Assoc.* **31**, 1691–1702(1939). The values of "presettling" prior to coagulation are stated. Flocculation results in grouping finely divided suspended solids into small lumps with good settling properties. Collision of the particles is necessary, brought about by mol. energy or mech. motion. Various factors such as addn. of electrolytes, addn. of solid material and flash mixing are discussed. The benefits and savings in the ensuing treatment are described. D. K. French

Coagulation of natural waters with aluminum sulfate at low temperatures. B. A. Skopintsev and M. T. Golubeva. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 10, 48–54; *Khim. Referat Zhur.* **2**, No. 3, 102(1939); cf. *C. A.* **33**, 7487. In expts. with Moscow River water at temps. of 2–4° and of 17–19°, the effects of the dose of the coagulant, alky. of water, mixing of water, presence of turbidity, addn. of lime and addn. of Muttovskiĭ alumina were investigated. Hydrolysis of the added $Al_2(SO_4)_3$ also was investigated. The most effective methods for the formation of flakes at low temp., which at the same time sufficiently purify the water, are mixing, addn. of an artificial suspension in the form of clay turbidity or of milk of lime, and the addn. of Muttovskiĭ alumina. During the introduction of the suspension it is necessary to add exact amts. of the substance since an excess of the clay turbidity causes a considerable lowering of the clearness of the coagulated water, while an excess of CaO causes an increased pH of the water and an accumulation of Al. W. R. Henn

Coagulation of soft waters with iron salts. Geo. E. Willcomb. *J. Am. Water Works Assoc.* **31**, 1703–22 (1939).—Experiences at Albany, N. Y., are described. The water has temporary hardness under 50, color, Mn and Fe. Ferric sulfate was finally used successfully. Lime was used, and when the pH was 9.0 to 9.5 Mn was removed as well. With Ferrisul costs were lower than with alum. Colloidal org. matter interferes, and floc formation is prevented. Complete soln. of the coagulant is most important for efficient results. D. K. French

Performance of upward-flow basins at St. Petersburg. Robert W. Sawyer. *J. Am. Water Works Assoc.* **31**, 1755–62(1939).—In a plant, over 4 years old, lime-treated water is carried to the bottom of the treating tank and then rises through, and is filtered by previously pptd. sludge. Results have been good and operating and maintenance costs are low. D. K. French

The aging of reservoir waters. Lee T. Purcell. *J. Am. Water Works Assoc.* **31**, 1775–1806(1939).—During storage, changes, both phys. and chem., occur which affect the quality of the stored water. Mostly these changes are good. Harmful changes usually occur in the first years of the reservoir's use. Based on observations made on different reservoirs, the nature of these "aging" changes is outlined. When the water ceases to improve the reservoir can be considered "aged." Changes in color, Fe, Mn, CO_2, dissolved O, H_2S and microörganisms, which can mostly be detd., are the guides to this aging. D. K. F.

Determination of sulfates in natural waters by nephelometric titration. Ts. I. Krasnovskaya. *Lab. Prakt.* (U. S. S. R.) **14**, No. 8, 19–20(1939).—Sulfate is pptd. with $BaCl_2$ and the ppt. compared nephelometrically with a ppt. from a known amt. of a standard soln. of $(NH_4)_2SO_4$. The detn. should be performed so that the times of the reaction in the 2 cylinders of the nephelometer are as nearly the same as possible. The method is especially suited to detns. in the field. Analyses of natural waters by the nephelometric and the gravimetric method, resp., gave in mg. SO_3/l.: 84.0, 83.98; 47.0, 47.99; 18.0, 18.92; 19.0, 18.37; 16.0, 14.26; 68.0, 68.83; 44.0, 42.37; 18.0, 17.82; 18.0, 17.55; 28.0, 27.70. W. R. Henn

Determination of the alkalinity of river water by means of a galvanometer. G. M. Vainshtein. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 8–9, 57–60; *Khim. Referat. Zhur.* **2**, No. 3, 87(1939).—An app. for the visual detn. of the elec. cond. of water is based on the measurement of the inner resistance of a Daniel galvanic element. For the half elements, electrodes are immersed in 2 wide test tubes: the Cu electrode in the test tube with a $CuSO_4$ soln., and the Zn electrode in the test tube with a $ZnSO_4$ soln. The water under investigation circulates through a straight glass tube and closes the inner chain of the galvanic element. The wires of the electrodes are connected to a galvanometer whose signals are directly proportional to the elec. cond. of the soln. and, consequently, to the alky. of the water. A formula is given by means of which the alky. in mg. equiv./l. can be calcd. The described "continuous control" of the quality of river water can be registered by lights of an automatic registering app. W. R. Henn

The use of sodium azide in the Winkler method for the determination of dissolved oxygen. G. R. Barnett. *Sewage Works J.* **11**, 781–7(1939).—The addn. of 2% Na azide to the alk. KI reagent of the Winkler method for dissolved O is recommended to eliminate the interference of nitrites. E. Hurwitz. *Ibid.*—Satisfactory results were obtained with a 1% soln. of the azide and 1.5 ml. of acid in the acidification technique. It is applicable to all plant effluents and river samples. W. D. Hatfield

Removal of dissolved oxygen from water by chemical means. D. Ya Kagan. *Teplo i Sila* **24**, No. 2, 29–34 (1939); *Khim. Referat. Zhur.* **2**, No. 3, 101–2.—The object of the expts. was the removal of O from water to prevent corrosion of boilers. The method is based on the oxidation of Na_2SO_3 to Na_2SO_4. The exptl. equipment and the methods of the expts. are described. With an equiv. amt. of Na_2SO_3 the velocity of the reaction depends on the temp. (at 40–60° it is 6–7 min., at 80–100° 1–2 min.). Increase of the amt. of Na_2SO_3 increases the velocity of the reaction (with a 70% excess the reaction is complete in 2 min. at all temps.). The amt. of the dry residue of water (up to 100 mg./l.) has no effect on the process, but is injurious to straight-run boilers. To avoid a large excess of Na_2SO_3 (which increases the amt. of the dry residue), part of the O is removed by heating before treatment with Na_2SO_3. Admixts. of org. substances decrease the velocity of the reaction (up to 80°) and a larger excess of Na_2SO_3 is required. Inorg. salts (1% of Fe salts or 0.0001% of Cu salts) act as catalysts. Therefore, it is advisable to use tech. Na_2SO_3 (OST 3511). Na_2SO_3 is added directly to the vessel or to the water. At a high temp. the process is complete in a short time without excess of Na_2SO_3. Curves show the dependence of the reaction velocity on temp. and on concn. of Na_2SO_3. W. R. Henn

Molybdenum in mineral, mine and surface waters. I. P. Novokhatskiĭ and S. K. Kalinin. *Compt. rend. acad.*

sci. U. R. S. S. **24**, 278–9(1939)(in English).—Mo has been found in the thermal waters of Russia in quantities amounting to as much as 0.27 g. per l. In mine waters it amounts to 0.3 to 0.7 g. per l. It is absent from the waters of the salt lakes of Kazakhstan and from oil waters. The presence of Mo in certain horizons of mine waters and not in others is evidently connected with H-ion concn. 2 references. A. H. Krappe

A new method for the determination of suspensions (in water). B. M. Yasnov. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 2, 48–55; *Khim. Referat. Zhur.* **2**, No. 3, 79 (1939).—An app. was devised in which suspensions in water contained in a cylinder settle into a dish connected with a float. The amt. of deposit is detd. (by the depth of the immersion of the float) directly on a scale after 1, 2 and 3 min. and then after 5, 10 and 20 and more min. Curves of the deposition of suspensions were obtained for the unchanged and for the alkalinized Moscow River water and for the slime formed from the softening of waters of different degrees of hardness by the soda-lime method with a coagulation at 60–80°. Increase of the temp. of water to 40° increased the deposition velocity. The limiting velocity, with which a definite percentage of the suspensions is deposited, is called the percentage velocity of the deposition and it is the basic element in the no. of values which are necessary for the layout of the settling tank. W. R. Henn

The correlation between the carbon dioxide and mineral content of water and its corrosivity. Willem Rudolfs and T. T. Wong. *J. Am. Water Works Assoc.* **31**, 1909–25 (1939).—Oxygen seems to be necessary for initial corrosion; thereafter corrosion seems to increase with increasing CO_2 with or without bicarbonate. Natural and distd. waters contg. CO_2 corroded readily. Above 4 p. p. m. CO_2 in distd., and above 8 p. p. m. in natural waters, the rate was retarded, probably owing to the formation of protective coatings. In the presence of sulfates, corrosion is const., regardless of concn. of sulfate, but very little iron goes into soln. In discussing the mechanism of corrosion many new factors must be considered, which the authors describe as primary, secondary and tertiary, and which include chemicals and chem. equilibria and surface or protective films. D. K. French

The permissible quantity of lead in drinking water, the daily resorption of lead in a normal man and the question of chronic lead intoxication. J. F. Reith and L. W. van Esveld. *Nederland. Tijdschr. Geneeskunde* **83**, IV, 5632–9 (1939).—The authors consider 0.3 mg. of lead per l. as permissible after the water has been kept in the pipes for about 8 hrs. Recently laid lead pipes may contain 2 to 3 times as much. R. Beutner

Deacidifying of drinking water by means of magnesite. R. Strohecker. *Z. Untersuch. Lebensm.* **78**, 184–6(1939). —The water is passed through an app. in which part of it filters through magnesite and part through $CaCO_3$ (marble). The mixed filtrate has a pH between 7.5 and 8.4. M. M. Piskur

Chemical processes of deacidifying drinking water by means of Magno. Karl Holl. *Z. Untersuch. Lebensm.* **78**, 186–7(1939).—Polemic (cf. Plücker, *C. A.* **33**, 3937⁴). H. pointed out that fresh Magno contained 15% MgO and 5% $MgCO_3$, after use there remained about . MgO which may be blocked out of the reaction by the $CaCO_3$. He claimed that the treated water gained Mg while the Ca content remained the same as that of the untreated water. The $CaCO_3$ therefore acted only as ballast. M. M. P.

A method for the neutralization of acid mine waters. A. I. Veselov. *Tsvetnye Metal.* **1938**, No. 8, 26–8; *Khim. Referat. Zhur.* **2**, No. 3, 102(1939).—In order to overcome the premature wear of the water-pumping app., of cables and of air pipes, and the pollution of water reservoirs with mine water contg. free H_2SO_4, a mechanized method for the purification of mine water is proposed. The water is treated with milk of lime which is added directly into the absorption pipe of the pump. W. R. Henn

Bactericidal action of chlorine in short contact (with water) when introduced in front of the pump. N. G. Belyaeva. *Vodosnabzhenie i Sanit. Tekh.* **13**, No. 5, 62–7 (1938); *Khim. Referat. Zhur.* **2**, No. 1, 86(1939).—An excess of 0.8 mg./l. Cl was added instead of the usual 0.5 mg./l. directly in front of the pump so as to make the time of contact 4–5 min. Although the bacteriol. analyses showed pos. results the results were unreliable because 1–3 hrs. had elapsed until the samples were analyzed. During this time the residual Cl could have completed the sterilization. Therefore, addnl. parallel analyses with planting of bacteria colonies were performed 7 min. after the chlorination. In some cases the excess Cl has been preliminarily neutralized with $Na_2S_2O_3$. No differences in results were found. The following conclusions can be made: chlorination of clear spring water with a dose of 0.8 mg./l. by passing the water with Cl through a centrifugal pump causes a satisfactory bactericidal action in 5 min., and under these conditions the bacterial colonies planted after 1–3 hrs. can serve as a definite proof of the effectiveness of chlorination. W. R. Henn

Reaction of heavy doses of chlorine in various waters. A. E. Griffin. *J. Am. Water Works Assoc.* **31**, 2121–9 (1939).—The effect of increasing doses of Cl over the quantity necessary for sterilization is described. As more Cl is added, the residuals first increase, then decrease, sometimes disappearing, and then increase in proportion to the dose. Tastes and odors decrease and disappear with the dropping of the residual. Tastes and odors appearing afterward usually disappear with dechlorination. Records from several plants are given. D. K. French

A definition of "available chlorine." L. L. Hedgepeth and A. M. Buswell. *J. Am. Water Works Assoc.* **31**, 2135–6(1939).—Available Cl is the weight of Cl given by reaction of a given weight of sample (Cl- carrying material) under ideal conditions, with an excess of HCl, the results to be expressed in %. Several equations and supplementary definitions are included. D. K. French

Superchlorination for taste and odor control. J. M. Lloyd. *J. Am. Water Works Assoc.* **31**, 2130–4(1939).—Superchlorination at Tyler, Tex. eliminated tastes and odors, partly oxidized Mn, and killed bacteria. The filter load was reduced and filter runs were lengthened. 6.2 p. p. m. Cl was used. D. K. French

Iodide technique for colorimetric determination of chlorine in water. F. W. Gilcreas and F. J. Hallinan. *J. Am. Water Works Assoc.* **31**, 1723–33(1939).—A colorimetric test, based on the liberation of I from KI by Cl, for the detn. of free Cl in water. Technique and reagents are described. As the procedure is complicated, the method will probably not be used where nitrates or Mn interferes. D. K. French

Removal of fluorine from potable waters. P. K. van der Merwe. *Nature* **144**, 668(1939). -A simple and inexpensive method for removal of F from natural waters by the addn. of superphosphate and pptg. $Ca_3(PO_4)_2$ by the addn. of lime is described. E. D. Walter

A uniform basis for activated carbon comparison. W. A. Helbig. *J. Am. Water Works Assoc.* **31**, 1931–44 (1939).—The efforts to find a basis of C comparison whereby adsorption tests on one type of odor can be correlated with tests on another type are described. The phenol value and threshold odor tests are used with many substances. A formula is suggested ($G/T.O. = Gp$) in which G is the gravimetric concn. of the odor-causing substance, $T.O.$ the odor at this concn. and Gp (a const.) the gravimetric concn. at the threshold of odor perceptibility. Results are not very consistent. Suggestions as to future work are made. D. K. French

Illinois's experiences in lime softening with short-time upward-flow clarification. H. A. Spafford and C. W. Klassen. *J. Am. Water Works Assoc.* **31**, 1734–54(1939). —The basic principles of the "precipitator" and the "accelator" involve first the bringing of the chemically treated water into intimate contact with freshly pptd. sludge and, second, using this sludge as a filtering medium, the water passing upward and the newly formed particles being trapped in, adsorbed or pptd. on the larger and heavier sludge particles. Clarification is rapid. Split treatment is often used with waters high in Mg, one portion of water

being overtreated in one basin and then in a second basin being mixed with a second portion of untreated water. D. K. French

Permutite or sodium hexametaphosphate for water softening. N. Meshcherskiĭ. *Legkaya Prom.* **17**, No. 11, 103–8(1938).—Cost data on construction and operation of water-softening installations having capacities of 2000 cu. m./day show that permutite is more economical than Na hexametaphosphate. B. Z. Kamich

Preventing internal corrosion of boilers by protective coatings and films. Edward Ingham. *Brit. Clayworker* **48**, 272–3(1939).—A small amt. of Ca scale will prevent corrosion. If the feed H_2O does not contain scale-forming materials, a coating may be formed by adding lime to the feed supply. The lime must be first slaked and it may then be added directly to the boiler. Only a very light coating should be formed so that the efficiency of the heat transmission will not be appreciably reduced. As an alternative to introducing lime into the boiler, the internal surfaces may be lime-washed at cleaning time. A cement wash may be applied. Expts. show this to be good practice as the cement is easily applied and its adhesiveness enables it to resist strongly the tendency for its removal, caused by repeated changes of temp. and pressure. Satisfactory results have been obtained with distd. gas tar and graphite. A coating of 0.02 in. is effective and such coatings will adhere firmly to the boiler surfaces. A red lead coating has sometimes been employed for protection but it soon peels off under the action of boiling H_2O. E. C. P.

Service lives of water mains. Reeves Newsom and F. H. Aldrich. *J. Am. Water Works Assoc.* **31**, 1625–54 (1939).—The Springfield, Mass., Water Works have records going back 75 years. As the transmission and distribution mains represent rarely less than 50% and often approach 80% of the total value of the complete system, data as to the life of such systems are needed. In 1864 wrought iron, cement-lined and coated pipe began to replace the original wood pipe, and the records begin. Wrought iron, cement, cast iron, steel and transite pipe are used. Cast iron pipe was rarely replaced owing to depreciation. The original cement pipe has been practically all replaced. Its av. life was 25.67 years for 2, 3 and 4″, and 31.1 years for 6, 8 and 10″. Life increases with diam. of pipe. Cast iron pipe life seems longest. D. K. French

Water and sewage works in Chili. Leonardo Lira. *J. Am. Water Works Assoc.* **31**, 1949–56(1939).—No town in Chili with over 5000 population is without its public water supply, and no city of over 10,000 lacks a sewerage system. Methods of management and control are summarized. Results are unusually good. D. K. French

Trends in sewage treatment. Wm. A. Hardenbergh. *Sewage Works J.* **11**, 803–10(1939). W. D. Hatfield

Chemical coagulation of sewage. XI. Effect of soluble matter on coagulation. Harry W. Gehm. *Sewage Works J.* **11**, 738–51(1939); cf. *C. A.* **33**, 3044[6].—Coagulation expts. with different types of sewages and groups of substances present in sewage, together with addns. of pure chemicals representing possible sewage constituents, have shown that the amt. of dispersed matter removed by a given coagulant varies in the same sewage when samples are taken at different times of the day. Org. rather than inorg. matter is responsible for the coagulant demand. However, no correlation between the gross amt. of org. matter in the Scitz filtrate and the coagulant demand is evident. A close correlation of the ammonia N content of sewage and the coagulant demand exists. Although ammonia itself plays no part it appears to be an index of the quantity of urine present. Urea, uric acid, creatinine, hippuric acid and other org. substances found in sewage have no effect on the demand. This is possibly due to transition products present in decompg. urine or formed by combination. W. D. Hatfield

Colloids in sewage and sewage treatment. I. Occurrence and role. Willem Rudolfs and Harry W. Gehm. *Sewage Works J.* **11**, 727–37(1939).—A crit. review of the literature on colloids in sewage and sewage treatment indicates that various methods of measurement produce widely varying results. 31 references. W. D. H.

The true oxygen consumption of sewage and a method for its determination. A. M. Dzyadzio. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 8–9, 117–25; *Khim. Referat. Zhur.* **2**, No. 3, 80(1939).—The different methods of Kubel, of Schulze and of Tyurin for the detn. of the O consumption of sewage and of org. substances were verified. The new method is: Pour into a flask equipped with a reflux condenser a 5% soln. of KIO_3, add some concd. H_2SO_4 soln. and 5 cc. of the liquid under investigation and 2–3 beads or a capillary. The concn. of H_2SO_4 should be 65–80% by vol. Heat gradually to 200°. The oxidation of the org. substance begins with an evolution of I vapors and can be considered completed when the evolution ceases. Cool the flask, add 40–50 cc. of H_2O, transfer the contents of both the exptl. and the control flask into larger flasks, dil. with water to 300–400 cc., add 1 cc. of a 10% soln. of KI, stopper, place for 10–15 min. in a dark place and titrate with a 0.1 *N* $Na_2S_2O_3$ soln. By this method 14 org. prepns. were investigated. The error did not exceed 2–3%. By far the most org. substances were oxidized to 100% in limits of exptl. errors. The method is superior not only to the methods of Kubel and of Schulze for the detn. of the O consumption but also to the method employing $K_2Cr_2O_7$. W. R. Henn

The use of high-rate trickling filters. C. M. Stanley and H. S. Smith. *Bull. Assoc. State Eng. Soc.* **14**, No. 4, 69–76(1939); cf. *C. A.* **33**, 3043[5].—The authors describe the high-rate filter and its loading and deal with its performance, costs, advantages and disadvantages. The patent situation is briefly discussed. J. M. Noy

Carbon and nitrogen transformations in the purification of sewage by the activated sludge process. II. Morphological and biochemical studies of zoögleal organisms. H. Heukelekian and M. L. Littman. *Sewage Works J.* **11**, 752–63(1939); cf. *C. A.* **33**, 7450[9].—A study of the morphological and cultural characteristics of 14 cultures of zoögleal bacteria isolated from activated sludges proved that they were indistinguishable from *Zooglea ramigera* described by Butterfield (cf. *C. A.* **29**, 5559[2]). Pure cultures of *Zooglea ramigera* decomp. simple and complex carbohydrates, proteins and soaps of fatty acids similar to natural sludges. The av. pure culture sludge-index was 54 under conditions which would produce extreme bulking of natural activated sludges. Pure culture sludges were stable and could not be made bulky. The chem. compn. of the pure culture sludges was 44.9% C and 9.9% N_2. W. D. Hatfield

Continuous digestion of mixtures of sludges from domestic sewage and packing-house wastes. O. J. Knechtges, Francis M. Dawson and M. Starr Nichols. *Sewage Works J.* **11**, 819–27(1939).—Twenty-five digestion expts. were run in 20-l. bottles with domestic and packing-house sludges. The sludges were fed in daily addns. of 2–18%. The digestion period was 100 days. The results show a distinct advantage obtained in the rate of digestion when packing-house sludge and domestic sludges are mixed. Comparison of results of batch and continuous digestion shows conclusively that the prediction or rates of sludge fermentation is most reliable when based on expts. in continuous digestion. W. D. Hatfield

Filtration tests with elutriated and unelutriated digested solids. Paul D. McNamee. *Sewage Works J.* **11**, 764–73(1939).—Digested sludge elutriated by countercurrent washing with 2.5 vols. of water can be coagulated with 1/3 the amt. of $FeCl_3$ usually needed. The alky. test is a convenient measure of the degree of elutriation. The HCO_3 ion and not the NH_4 ion is thought to be the cause of the $FeCl_3$ demand of nonelutriated sludge. W. D. H.

Digestion studies on paper pulp. Milton T. Hill. *Sewage Works J.* **11**, 864–76(1939).—Mixts. of paper pulp and fresh sewage sludge, when added to well-seeded sludge, digested satisfactorily in ratios of 2:13. No noticeable deleterious effects upon digestion were noticed with C to N_2 ratios from 20 to 52.6. The volatile solids in paper pulp produced more gas than sewage solids. The CO_2 content of the gas was greater than normal. W. D. H.

A unique and effective determination of the extent and degree of pollution by sewage of the west and north shores

of the city and county of San Francisco. J. C. Geiger, C. G. Hyde and A. B. Crowley. *Sewage Works J.* **11**, 811–18(1939).—Bacteriol. examn. of the water was made by collecting weekly samples from 18 carefully selected sampling stations. The presence of coli-aerogenes organisms was the criterion used to est. the degree of pollution in dilns. of 10, 1, 0.1, 0.01 ml. Samples were taken for a period of 52 weeks. Serious contamination was demonstrated at all stations. The data constituted the basis for quarantine against bathing at the beaches in question. W. D. Hatfield

Aspects of governmental policy on stream-pollution abatement. Herman G. Baity. *Am. J. Pub. Health* **29**, 1297–307(1939). J. A. Kennedy

Preventing rust formation in water-storage equipment. Geo. J. Thomson (to Rusta Restor Corp.). U. S. 2,176,514, Oct. 17. A method of preventing rust formation in water-storage equipment comprising a metallic water tank having a metallic tubular casing of relatively small diam. depending centrally from it and a water-supply pipe extending through the casing and into the lower portion of the tank involves providing a source of d. c., connecting the pos. side of the current to an electrode immersed in the water in the tank adjacent the upper end of the tank, and connecting the neg. side of the current to the exterior of the casing adjacent its lower end.

Apparatus for softening water by percolation through materials such as baked fire clay. Samuel Smith. U. S. 2,176,549, Oct. 17. Various structural and operative details of an app. into the upper portion of which the water is atomized.

Clarifying sewage. Henry P. L. Bendel. U. S. 2,177,167, Oct. 24. App. is described, and a process for mechanically clarifying sewage contg. liquid matter and suspended solid matter which tends to rise in the liquid matter; it involves conducting unclarified sewage to a clarification chamber at a relatively high velocity, feeding the sewage into the lower part of the chamber so as to allow suspended solid matter to rise, intercepting the rising matter in a part of the chamber below the surface of sewage in the chamber, withdrawing intercepted matter from the part of the chamber and withdrawing clarified sewage from the chamber.

Electrical control system for sewage pumping and ejection apparatus. Robert E. Sykes and John M. Gray (to Yeomans Bros. Co.). U. S. 2,177,083, Oct. 24. Various structural, elec. and operative details.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

The loess soils of the Beersheba region of Palestine. A. Reifenberg. *Empire J. Exptl. Agr.* **7**, 305–10(1939).—The loess territory owes its origin mainly to the dust storms of the desert. The loess is yellow and consists mainly of grains of fine quartz intermixed with chalky particles. Chem. analyses show that these soils are rich in Ca, comparatively rich in mineral nutrients, deficient in org. matter and N and poor in Fe and Al. They are easily permeable to water and air and of a texture most suitable for cultivation. The aspects of irrigation with saline water are given as well as the salt-resistance of various plants. Irrigation with water contg. 1500 mg. of Cl per l. cannot be recommended since the salts tend to accumulate in the soil, and owing to the scanty rainfall they are not leached out in the rainy season. J. R. Adams

The soils of the 3500 Farms Scheme area, Western Australia. L. J. H. Teakle. *J. Dept. Agr. W. Australia* **16**, 202–30(1939); cf. *C. A.* **33**, 8873[5].—A brief description of the general geological, vegetation, climatic and soil factors is given for that portion of the 3500 Farms Scheme area which lies south of Southern Cross and between Newdegate and Salmon Gums. The woodland and mallee soils of this area are of the solonetz type; $CaCO_3$ accumulation in the subsoil is characteristic; and, the surface horizon is typically noncalcareous except in 1 group assocd. with morrel timber. High concn. of H_2O-sol. salts in the subsoils is apparent. The soils of the woodland and mallee areas fall into 8 main groups and each of these groups is described in some detail. The virgin soils of 7 of these groups are characteristically more or less saline and the heavy-textured types of groups are generally excessively saline. The soil salinity problem is largely confined to heavy-textured soils. The incidence of soil salinity in this area is related to the permeability of the soil to moisture. J. R. Adams

A soil survey of the Denmark Agricultural Research Station, Denmark, Western Australia. G. H. Burvill. *J. Dept. Agr. W. Australia* **16**, 243–57(1939).—Fourteen soil types have been mapped principally on the basis of soil profile features. Of these, 9 are types recognized in a larger district survey (cf. Hosking and Burvill, *C. A.* **32**, 5556[2]) while the remaining 5 are new types. These soils fall into 3 groups. Group I. These soils are gray, yellow and light-brown sands more or less gravelly, with yellow to white clay subsoils. The pH of the surface soil is 5.5–6.0. Group II. These are well podzolized gray sands, with "coffee rock" or ferruginous hardpans or coffee-stained layers in the subsoil; the surface pH is 4.4–4.8. Group III. These are chocolate, dark-gray and brown loams with clay subsoils formed over basic rocks with a surface pH of 6.0. Detailed descriptions of the different types are given. In general, both total salts and chlorides occur in small quantities only. J. R. Adams

Arsenical soils of the Waiotapu Valley. Evidence of stock poisoning at Reporoa. R. E. R. Grimmett. *New Zealand J. Agr.* **58**, 383–91(1939).—Much of the soil of the district is composed of Fe and Al hydroxides and ferruginous springs occur. Detns. of As by the Reinsch test showed that arsenical soils and springs extended over 2000 acres of farming land besides an undetd. area in the Waiotapu thermal and forestry reserves. Several of the mud volcanoes gave strong tests for As and Champagne Pool contained 0.86 grains of As_2O_3 per gal. Analyses of 65 muds and soils showed that the former contained 0.0069 to 1.9% As while representative samples of soil to a depth of 9 in. in pasture lands varied from 0.0008 to 0.525% As. The As content of 39 samples of water from springs, streams and surface depressions varied from a trace to 26 grains per gal. Fresh mud deposited on farm lands by the Waiotapu River during flood contained As. Both hot and cold springs contained As in soln. which was deposited as an arsenical limonite or as sulfide in different places. In one extinct hot-spring area masses of deposited silica contain pockets of As_2S_3 and an orange-yellow crust under the surface mud of an adjacent water hole consisted of silica with 5% of orpiment and realgar. The As in farm lands is present in the water-sol., acid-insol. and acid-sol forms. The urine of cattle grazing in As-contaminated areas contained 0.34 to 5.8 mg. of As_2O_3 per 100 cc. while the milk contained 0.01 to 0.20 mg. per 100 cc. The As_2O_3 content of the urine of a cow fed H_2O-sol. As rose to 5.9 mg. per 100 cc. before death occurred but very little As passed into the milk which contained up to 0.050 mg. per 100 cc. when the animal showed evidences of As poisoning. The liver and kidney of the animal contained 15 and 29 mg. As_2O_3 per 1000 g. of wet wt., resp. The As in Fe oxide mud is readily assimilated but when fed in sublethal amts. to steers was excreted as rapidly in the urine as it was

taken in. Feeding As sulfide mud to steers caused no increase in the As content of the urine indicating that this form of As is nontoxic. In 9 cases of As poisoning the As content of the liver varied from 2.7 to 32.0 mg. and that of the kidney from 1.6 to 33.5 mg. As_2O_3 per kg. of wet wt. The As content of the urine of cattle feeding in arsenical areas was highest in Aug. and Sept. when feed was scarce and there was much surface water. No close agreement between the level of As in the urine and the condition of the animals was found. The Co content of autumn and spring pastures in As areas varied from 0.030 to 0.108 p. p. m. of dry matter, most samples being above 0.05 p. p. m. which is sufficient for cattle but below the requirement for sheep. *Ranunculus rivularis*, which grows to slight extent in the As area, was fatal when fed to sheep but is not thought to be the cause of the cattle sickness. Ten samples of pasture contained 0.6 to 23 mg. As_2O_3 per kg. of air-dry material with most samples contg 3–9 mg. per kg. Oat straw and grain from arsenical soil contained 4 and 3 mg. As_2O_3 per kg., resp., and were thus safe for stock. Poisonous diethylarsine can be produced by the action of molds on org. matter contg. As. It is concluded that As is responsible for only a small mortality, the greatest danger being to cattle having access to arsenical mud or water. Clean, growing pasture on arsenical soils is usually harmless. Colin W. Whittaker

Soil characteristics, topography and lesser vegetation in relation to site quality of second-growth oak stands in Connecticut. Herbert A. Lunt. *J. Agr. Research* **59**, 407–28(1939).—The soil samples collected in this study were analyzed for total N, loss on ignition, pH, exchangeable H, total base capacity, percentage satn., cond., moisture equiv., total colloids and sol. nutrients by Morgan's quick test method. The native fertility of the soil is an important detg. factor in stand compn., but this is a controlling factor in site quality only in those situations where other environmental influences are of minor significance. W. H. Ross

Investigation of the soil of young oak growth in the Liebenstein district of the royal domain of the house of Wurtemberg. K. Rehling. *Allgem. Forst- u. Jagd-Ztg.* **115**, 273–91(1939).—Relation of pH, phosphoric acid content, M, total protein N and phys. measurements of fine soil to growth is shown. J. McAfee

Considerations on the Bennett-Allison classification of Cuban soils. G. A. Regato. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 63–70; cf. *Soils of Cuba*, *C. A.* **22**, 2804.—The advantages of the system are pointed out O. W. Willcox

Cation-exchange properties of certain forest soils in the Adirondack section. R. F. Chandler, Jr. *J. Agr. Research* **59**, 491–505(1939).—On soils of similar geol. origin, the sugar maple-beach-yellow birch forest type produced a soil type which, in the surface layers, was less podzolized, had a higher pH value, and a larger percentage base satn. than soil profiles beneath stands of the red spruce-sugar maple-beech type, or the red spruce type. The differences between the latter 2 types were small. Evidence is submitted to indicate that the cause of these differences was assocd. with the Ca content of the foliage of the trees. A high correlation existed between total exchange capacity and percentage loss on ignition. Percentage base satn. and pH value were highly correlated when soils of similar org. matter content were compared. The apparent pK values of the various horizons indicated that the soil org. matter had a lower apparent pK value than that of the mineral soil. The values were somewhat higher for the hardwood profiles, indicating that weaker acids were involved. The lower apparent pK value of org. matter and hence the higher percentage base satn. at a given pH concn. explain why it is possible to have a lower pH value in the B_1 horizon than in the A_2 horizon of a humus podzol profile. W. H. Ross

Mineral content of pastures. Cobalt investigations at the Cawthron Institute, period 1938–39. Theodore Rigg. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 60–3 (1938–39); cf. *C. A.* **33**, 2640⁶.—In Ashburton County, the loess soils of the Plains and the recent soils of the Ashburton and Rangitata Rivers produced pastures having a satisfactory Co status (av. 0.17 and 0.23 p. p. m. Co, resp.). In Southland, pastures located on recent alluvial soils had a satisfactory Co status, whereas those assocd. with the loess soils of the Invercargill district tended to be low in Co (0.04–0.06 p. p. m.). In the Nelson-Collingwood districts, certain soils derived from granite contained approx. 1 p. p. m. Co, but the pastures assocd. therewith contained only 0.04 p. p. m. Soils derived from limestone, basic rocks and Ordivician slates were much higher in Co, but the pastures assocd. therewith were not correspondingly high in Co. Pastures located on conglomerates, sandstones and dune sands contained 0.03–0.06 p. p. m. Co. On the West Coast, the av. Co content of pastures assocd. with recent alluvial soils exceeded 0.2 p. p. m., whereas pastures located on pakihi soils, dune and recent blown sands, leached gravel terraces and limestone-country soils were low in Co. The Co content of pastures was increased from 0.04 p. p. m. on the control plots to 0.08, 0.16 and 0.37 p. p. m. on those receiving 0.25, 0.5 and 2 lb. Co chloride per acre, resp. CoO was successfully used in the manuf. of *cobaltized superphosphate* contg. 0.1% Co 90% sol. in water. Samples of early spring pasture tended to be higher in Co than those of autumn pasture. Ground limestone contg. 5 p. p. m. Co and applied at the rate of 3 tons per acre caused a marked increase in the Co content of the pasture. K. D. Jacob

The biological synthesis of ammonia in soil and water. Serge Winogradsky. *Compt. rend.* **209**, 616–20(1939); cf. *C. A.* **24**, 3072, **29**, 8203⁴.—NH_3 can be found in the distillate from a culture of *Azotobacter vinelandii* (green strain) or *A. agilis* (*Azomonas*) grown on ethanol or Na butyrate, with Ca and Mg carbonates. The sum of NH_3 liberated and fixed N of the culture exceeds the initial fixed N. Excess nutritive element decreases NH_3 evolution. J. McAfee

Effects of varying amounts of ammonium sulfate on moisture content of Lipa clay loam at wilting of rice plants. Felipe R. Lopez. *Philippine Agr.* **28**, 321–37(1939).—A study was made of the moisture contents of Lipa clay loam at the time of wilting of leaves of rice, variety Inintiw, when supplied with varying amts. of $(NH_4)_2SO_4$. There seems to be no definite relation between the amt. of $(NH_4)_2SO_4$ applied and the moisture content of the soil at time of wilting of seedling rice plants. In the vegetative and flowering stages the H_2O in the soil at time of permanent wilting seemed to increase with the amt. of $(NH_4)_2SO_4$ applied. Increasing amts. of H_2O remained in the soil of both fertilized and unfertilized pots at wilting time as the plants became older. With applications of $(NH_4)_2SO_4$ varying from 0 to 1.75 tons per hectare rice plants in the seedling stage were permanently wilted at 14.35 to 14.40% H_2O in the soil, plants in the vegetative stage at 15.73 to 16.97% and plants in the flowering stage at 17.93 to 19.54%. Colin W. Whittaker

Investigations on sugar cane on saline soils (solonchaks). Takeo Nagata and Sanziro Sasaki. *J. Sci. Soil Manure, Japan* **13**, 597–607(1939).—The facts that the alkali spots were always of lower elevation than the surrounding land and that the surface soil of the alkali spots was rich in clay fraction indicate that these spots were generally due to seepage water. The greater the distance from the alkali spot the more nearly normal was the growth of sugar cane. Juice of plants damaged by alkali was lower in Brix, sucrose content and apparent purity, and higher in reducing sugar. In the stalks total N, total ash, CaO, MgO, K_2O, Na_2O, SO_3 and Cl were high; CaO MgO: K_2O Na_2O was 2.28:4.74:54.50.38.48 and SO_3.Cl, 57.22.42.78; the ratios were independent of the degree of damage. These facts indicate that the damage was due to the high concn. of absorbed salt and of surrounding soil soln., not to the ratios of absorbed substances. Y. Kamoshita

Recent experiments with "minor" elements in Western Australia. I. A brief review of the "minor" element question in Western Australia. L. J. H. Teakle. *J. Dept. Agr. W. Australia* **16**, 116–19(1939); cf. *C. A.* **33**, 9515¹.—**II. Experiments with "minor" elements on the growth of potatoes, vegetables and pastures.** L. J. H.

Teakle and E. T. Morgan. *Ibid.* 119-28.—On the marly peat soils of the coastal swamps in the Albany district $MnSO_4$ is likely to benefit a variety of crops. Cu, in addn. to Mn, may be beneficial with some. A no. of crops are benefited by the addn. of Cu to a no. of acidic soils types, including swamp soils, soils of bottle brush flats and brown sandy soils of karri hills of the Albany district. No response is observed to the use of "minor" elements on the agricultural soils of the western coastal plain of Perth. Rates of application of 15 lb. per acre are sufficient for Cu sulfate or $MnSO_4$ and lower rates may be adequate. The residual effect of "minor" elements in the soil is observed in the growth of the crop grown the following yr. III. **Response of wheat to copper on light lands at Wagin.** A. M. Stewart and L. J. H. Teakle. *Ibid.* 135-43.—The use of Cu sulfate is beneficial to the growth of wheat on some light lands in the Wagin district. On the poorest soil type wheat fails to mature grain with superphosphate and K_2SO_4 but produces a good crop when Cu sulfate is used as an addnl. fertilizer. Cu sulfate improves the apparent health and vigor of the wheat throughout the growing period. Other "minor" elements fail to produce substantial increases in yield on any soil types. Borax and Zn sulfate interfere somewhat with germination. It can be expected that benefits from Cu will be shown in improved quality of pasture and in the health of animals grazing on the poorer gravelly sand soils. IV. **The effect of "minor" elements on the growth of wheat in other parts of the state.** L. J. H. Teakle and I. Thomas. *Ibid.* 143-7.—The use of "minor" elements for the growth of wheat on soil types at Cleary, Salmon Gums and Wongan Hills fails to improve the yield. Significant depression in yields results from the use of Zn sulfate, borax and various mixts. of "minor" elements on the acidic sandy soils of Wongan Hills. Zn sulfate is especially injurious. At Cleary, a "minor" element mixt. interferes with germination and yield of wheat but in the early growth stages causes the development of a deeper green color than in the controls. J. R. Adams

Minor elements in fertilizer practice. P. Menchikowsky. *Hadar* **12**, 47-50(1939).—A review with 15 references. Colin W. Whittaker

The effect of boron on the growth of wheat. Matuo Tokuoka and Syusm Zyo. *J. Sci. Soil Manure, Japan* **13**, 613-21(1939).—In sandy shale soils of Tertiary formation in Formosa, pH 6.7, seeds from plots to which more than 66.67 p. p. m. B was applied were not capable of germination. The growth of plants in plots treated with less than 3.33 p. p. m. B was poorer than that of the control in the beginning but was better later; more grain was produced. Slight toxic action of B was observed with 6.67 p. p. m.; notable toxic action at 20 p. p. m. Y. K.

The infiltration of potassium and phosphoric acid in the moor soils. Br. Tacke. *Ernahr. Pflanze* **35**, 307-8 (1939).—The absorption of K by high-moor soils was in agreement with that found previously (A. Konig, *Landw. Jahrb.* **11**, 1(1882)). The fixation of P in the fertilized upper layer of soil was considerably more than that of K, and the amt. of P reaching the lower layer (15-30 cm.) was proportionately smaller. The loss of K from the upper layer of tilled soils was greater than that from grass lands. John O. Hardesty

Retention of some phosphorus compounds by soils as shown by subsequent plant growth. John P. Conrad. *J. Agr. Research* **59**, 507-18(1939); cf. *C. A.* **33**, 1853⁹.—A soln. of each of a series of P compds. was allowed to percolate through a column of 3 pots contg. dry soil deficient in P. The growth of the subsequent crop of milo, whether increased or reduced according as the compd. used was beneficial or toxic, was taken as evidence of P retention. Yolo subsoil and Aiken loam soil were used in the tests. The former showed little retention of hypophosphites but somewhat more of phosphites, The P of HPO_3 reached the 2nd pot but that of the pyro- and orthophosphates was held in the top pots. Aiken soil held each inorg. compd. more strongly than did the Yolo soil. The Yolo soil retained the P of phytin in the top pot but held back the glycerophosphates only slightly. The Aiken soil retained the P of nearly all these compds. in the top pots. The phosphites and hypophosphites were toxic to milo while the meta-, pyro- and orthophosphates, if not too concd., and the glycerophosphates were beneficial when used in both soils. Phytin was beneficial on the Yolo soil and Na nucleate on the Aiken soil. The possible mechanisms by which the various compds. were retained are discussed. W. H. Ross

The solution of phosphorus and potassium in the soil. Kálmán Pallaghy. *Mezőgazdasági Kutatások* **12**, 196-9 (1939).—The contents of the same soils in P_2O_5 and K_2O were detd. by the Neubauer method in August 1936, March and July, 1937. The values are somewhat higher in the spring than in the summer. Since the deviations of parallel detns. are relatively high in Neubauer expts. the difference in the nutrient content of the soils in the various seasons may be of a considerable range. S. S. de Finály

The importance of an abundant supply of potash to German soils and plants, a contribution to the problem of "harmony of nutrients." L. Schmitt. *Ernahr. Pflanze* **35**, 301-6(1939); cf. *C. A.* **33**, 7971.—Pot expts. were carried out with spinach, tobacco and ray grass receiving N, P and K in various combinations. Symptoms of K deficiency occurred in plants receiving no K. Increasing applications of K in conjunction with increasing N showed that the K was more responsible for increased yields. Amts. of vitamin C, both in oxidized and reduced forms, and of carotene in the spinach and ray grass are tabulated for different fertilizer applications. Results with spinach are graphically represented showing the relationship between the dry matter and K contents of the plant and the dehydrogenation of the ascorbic acid. The ascorbic acid in spinach was more stable with high applications of K. With ray grass a high carotene content usually corresponded to a low residual value for ascorbic acid. John O. Hardesty

Some experiments on potassium fertilization. A. Rothenberg. *Hadar* **12**, 211(1939).—One-hundred barley plants grown 18 days in an unfertilized mixt. of kaolin and sand irrigated with well water contg. 35 mg. Cl per l. contained 30 mg. less K and 3 mg. less HPO_4^{--} than did the original seed, but contained 0.9 mg. more Na, 7 mg. more Ca and 7 mg. more Cl. When 0.1246 g. KH_2PO_4 and 0.277 g. KNO_3 were added the plants contained 39 mg. K, 0.8 mg. Na, 7 mg. Ca, 37 mg. HPO_4^{--} and 5 mg. Cl more than the original seed. In the unfertilized soil K was actually lost, but 37% of the K added as fertilizer was taken up in 18 days. A red sandy loam of the coastal belt contained SiO_2 93.68, Al_2O_3 3.23, Fe_2O_3 1.36, H_2O 0.89% and a trace of CaO. The exchangeable cations were Ca 2.5, Mg 0.9, K 0.3 and Na 2.6 mg. equivs. in 100 g. Available K and P were lacking and the soil contained only a trace of N. K fertilization of maize grown on this soil was very effective. Colin W. Whittaker

The effect of calcium arsenate upon the productivity of several important soils of the cotton belt. Clarence Dorman, Frederick H. Tucker and Russell Coleman. *J. Am. Soc. Agron.* **31**, 1020-8(1939).—Neither germination nor seedlings were injured on any of the 7 soil types tested until 400 lb. per acre or more of $Ca_3(AsO_4)_2$ was applied. The greatest injury from the heavier applications occurred in the seedling stage and the extent of this injury depended upon the nature of the soil type. Crop yields from oats, Austrian peas and hairy vetch planted immediately after the As was applied and 1 yr. later showed that yields were not affected except by heavy treatments and much of their toxicity was lost during 1 yr.'s time. Oats seemed more sensitive to As than Austrian peas and hairy vetch, but all crops grown on Norfolk, Ruston and Cahaba sandy loams were injured more than those grown on heavier soils. Large amts. of H_2O-sol. As did not accumulate in any soil until 400 lb. of $Ca_3(AsO_4)_2$ was added, and then only in the sandy soils. Those soils which were most sensitive to arsenates contained the smallest amts. of clay, Fe, Al, Ca and Mg. Houston clay loam, the soil least affected by $Ca_3(AsO_4)_2$, contained the largest quantities of these constituents. From these data it appears that the av. application of $Ca_3(AsO_4)_2$ for insect control will probably never

cause enough accumulation to injure crops usually grown on the soils used in this study. J. R. Adams

The consumption of inorganic nitrogen by the root-nodule bacteria of leguminous plants. II. Syuzi Isizawa. *J. Sci. Soil Manure, Japan* **13**, 560–8(1939); cf. *C. A.* **33**, 1628⁷.—Ammonia and nitrate N were readily utilized by broad-bean bacteria; nitrite was utilized less readily. Y. Kamoshita

Studies on control of mineral damage to plants. I. Sulfide. II. Lime and organic fertilizer. Goro Matuki and Siniti Katutani. *J. Sci. Soil Manure, Japan* **13**, 639–52(1939).—In protecting plants such as paddy rice and barley from damage by inorg. agents, Na_2S and CaS are suitable to ppt. sol. Cu, Pb and As salts. Na_2S is less suitable than CaS for protection of paddy rice, but more suitable for barley. This is attributed to differences in H-ion concn. produced by the 2 sulfides. Duration of the protecting power differs according to the kind of injurious substance and to the soil condition. CuS is easily oxidized to sulfate in the presence of air and moisture and is rather unstable, especially in water-logged soil. PbS and As_2S_3 are more stable than CuS. The soils contg. inorg. substance harmful to plants are inclined always to be acidic. Addn. of lime is considered the most suitable means of protecting the plant. For paddy rice the amount of lime must not be sufficient to produce an alk. reaction, as this hinders the plant growth. Organic fertilizer is not a suitable protecting agent, especially when Na_2S is added. Y. Kamoshita

Fertilizer requirements of sugar cane in Egypt. IV. Further phosphate experiments. Arthur H. Rosenfeld. *Ministry Agr., Egypt, Tech. Sci. Service, Bull.* No. 210, 23 pp.(1939); cf. *C. A.* **31**, 2729², 8792⁵.—$Ca(NO_3)_2$ was considerably more effective than superphosphate in increasing the yield of cane. There was no indication whatsoever of the supposed ripening effect of phosphate fertilizer on sugar cane. The trend was rather consistently toward a slight decrease in cane quality as a result of phosphate application. **V. Time and number of nitrogenous fertilizer applications.** *Ibid.* No. 213, 16 pp. K. D. Jacob

Summary of results of fertilizer experiments on black currants, raspberries and strawberries at Long Ashton, 1924 1937. T. Wallace. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 17–39(Pub., 1939).—See *C. A.* **33**, 7947⁷. K. D. Jacob

The fertilizing of cricket-bat willow trees. H. P. Hutchinson *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 249–53(Pub., 1939).—See *C. A.* **33**, 7947⁵. K. D. Jacob

The spreading ability of fertilizers and laboratory methods for determining it. N. E. Pestov and A. N. Mironova. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 33–6(1939). An app. is described for detg. the amt. of fertilizer which flows through a slit in the bottom of a jar. Comparison of the case with which a no. of fertilizers flow from this app. and from a funnel permits construction of a scale by which various fertilizers can be graded as to ease of spreading. The moisture content of the fertilizer is an important factor. H. M. Leicester

Studies on the fertilizing value of Mayon Volcano ash. II. Beneficial effects of adding ammonium sulfate. Rafael B. Espino. *Philippine Agr.* **28**, 260–70(1939); cf. *C. A.* **34**, 210¹.—Liberal addns. of Mayon Volcano ash to Lupa clay loam gave good results on radishes and tomatoes when supplemented with the correct amts. of $(NH_4)_2SO_4$. Mayon Volcano ash is not toxic to plants. It contains mineral nutritents valuable to plants when applied to a soil rich in N or to an unfertile soil if accompanied by $(NH_4)_2SO_4$. Colin W. Whittaker

Composition of superphosphate (super) and Nauru phosphate. R. A. Taylor. *Queensland Agr. J.* **52**, 549–53(1939).—A typical analysis of Nauru Island phosphate rock is total P_2O_5 39.8, $Fe_2O_3 + Al_2O_3$ 0.7, F 0.5, total CaO 50.4, loss on ignition 3.0 and free water 1.5%. A typical analysis of the superphosphate produced from this rock is H_2O-sol. P_2O_5 20.5, citrate-sol. P_2O_5 0.5, citrate-insol. P_2O_5 1.0, F 0.3, $Fe_2O_3 + Al_2O_3$ 1.0, insol. material 2.2, CaO 29.5, SO_3 28.4, free water 7.6 and combined water 4.0%. K. D. Jacob

Compost. S. D. Timson. *Rhodesia Agr. J.* **36**, 194–219, 285–316(1939).—An extension and revision of a previous paper (*C. A.* **32**, 4706²). Colin W. Whittaker

Experiments on the manurial value of sewage sludge from septic tanks. H. T. Cranfield. *Empire J. Expll. Agr.* **7**, 319–29(1939).—The great bulk of ordinary sewage sludge as produced in septic tanks and drained in lagoons has a compn. falling within the following limits: moisture 50–80, org. matter 10–30, total N 0.5–1.0, P_2O_5 0.1–0.5, K_2O 0.03–0.3 and ether-sol. matter 1–9%. Such sewage sludge has considerable value as an org. fertilizer. To obtain good results with sewage sludge adequate dressings of inorg. fertilizers must be applied. The decompn. of fresh sewage sludge may be slow during dry periods, particularly on light land, since adequate moisture is necessary for fairly rapid decompn. The heaping of sludge for a yr. or 2, or even composting with soil, materially improves the utilization of this manure by producing a more friable material which can be distributed more evenly, and in which the decompn. is rendered more rapid. On certain soils an appreciable residual fertilizing value may accrue in favor of the second yr.'s crop. J. R. Adams

The highest temperatures which occur in stored calcium cyanamide on contact with water. H. H. Franck and Carl Freitag. *Angew. Chem.* **52**, 623–5(1939).—The highest temps. observed on slow addn. of H_2O at 100° to white (19.9% N) and black (23.7% N) $CaCN_2$ and to CaO were 120–5°, 150–60° and 370–400°, resp. If highly combustible materials, such as nitrates, are not present, there is no danger of ignition. Thermodynamic calcns. of max. temps. are presented. 6 references. K. Kammermeyer

Experiments on the control of pests of apple nursery stock by means of dipping. Woolly aphid and red spider. Progress report No. I. H. G. H. Kearns and E. Umpleby. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 72–7(Pub., 1939).—The roots of lifted nursery trees were freed as completely as possible from soil and were completely immersed in an emulsion contg. grade A tar oil 3, grade A petroleum oil 3 and 40% sulfite lye 1.5%. The treatment gave high but incomplete controls of woolly aphid (*Eriosoma lanigerum* Hausm.) and red spider (*Oligonychus ulmi*). K. D. Jacob

Biology and control of Pseudococcus comstocki Kuwana on citrus in Palestine. E. Rivnay. *Hadar* **12**, 197–201 (1939).—Spraying with oil emulsions and tank mixt. (oil mechanically mixed with H_2O plus blood albumin as a spreader) did not give satisfactory results. Oil emulsions failed to pentrate the layer of wax and fumagine on the leaf. Green or yellow soft soap, dild. to a concn. of 1–1½%, softened the fumagine and in spray tests killed 85–90% but dried quickly and its effects did not last long. Thiocyanate in a sol. oil used at concns. of 0.33, 0.50 and 1% penetrated the fumagine and wax and killed over 95%. Residual oil from oil sprays leave a lasting film that is effective against the young crawlers. A S wash was entirely ineffective but gave a mortality of 70% when mixed with a sol. oil. Pyrethrum ext. in vegetable oil contg. an emulsifier gave a 60% kill when dild. to 0.33%. A combination of derris and pyrethrum was unsatisfactory as was also a product contg. derris alone when used at the rate of 1:500. Nicotine with a spreader gave a mortality of 70–80%. Colin W. Whittaker

Further experiments on control of vine moths with the help of sex scents. Bruno Götz. *Anz. Schädlingskunde* **15**, 109–14(1939); cf. *C. A.* **34**, 178⁸.—Expts. were made by which the attractant power of unfertilized females of the vine moths, *Polychrosis botrana* and *Clysia ambiguella*, was used for trapping the males. Such females were imprisoned in cages placed in the center of traps consisting of vertical surfaces covered with white paper coated with glue. The males, which usually appear earlier, are thus captured before they have fertilized the females. For comparison, glass traps baited with the best artificial attractant known, wine made from the marc of grapes with the addn. of 2% vinegar and 1% sugar, were used. The results showed that (for the resp. species) 25 and 23 times

as many moths were trapped in the male traps as by the bait, and, considering males alone, 38 and 52 times as many. The no. of moths captured depends on the weather, the direction of the wind, and the no. and age of the females. The attractiveness of the secretion is greater on the 2nd day than on the 1st, and continues throughout the adult life. This method of control will be practical only when the synthetic scents are available. E. J. S.

Tartar emetic as a control for the gladiolus thrips. W. G. Matthewman and A. G. Dustan. *Ann. Rept. Entomol. Soc. Ontario* **69**, 114(1938).—A spray composed of tartar emetic 2, brown sugar 8 oz. and water 2.5 gal. was slightly more effective than Paris green spray in controlling the thrips and caused no noticeable spotting of the foliage. The 1st application of the tartar emetic spray was made when the foliage was 6 in. tall and the treatment was repeated at weekly intervals for 6 weeks; enough spray was applied to cover the foliage with fine droplets, but not enough to wet the leaves completely. K. D. Jacob

Recent developments in cabbage-worm control on Long Island. H. C. Huckett. *Ann. Rept. Entomol. Soc. Ontario* **69**, 93-6(1938).—Pyrethrum dusts are generally more effective than derris and other rotenone-contg. dusts in controlling the insect pests of cabbage. K. D. Jacob

Control of the house cricket [Gryllus domesticus L.] L. Caesar and G. G. Dustan. *Ann. Rept. Entomol. Soc. Ontario* **69**, 101-5(1938).—In lab. tests pyrethrum powder, NaF and Na_2SiF_6 were highly effective against the house cricket. A bait composed of bran 25, NaF 1 lb., molasses 2 qt. and water 2.5 gal. is recommended for the control of crickets breeding in refuse dumps. The bait should be applied 3 times at weekly intervals, in the late evening to all infested parts of the dump. Crickets in houses can be controlled by placing a mixt. of equal parts of fresh pyrethrum powder and NaF in a ring 1 in. wide, enclosing an area about 6 in. in diam. in the center of a newspaper, and placing a small handful of dry oatmeal, as a bait, in the center of the ring. The dust ring should be heavy enough to cover the paper which is allowed to remain in a corner of the room until all crickets have disappeared. K. D. Jacob

Effective spacing of soil fumigants for field application A. L. Taylor. *Proc. Helminthol. Soc. Wash., D. C.* **6**, 62-6(1939). If k is the max. distance from the point of application of a soil fumigant to the point where it produces the desired results, the most efficient utilization of the fumigant is obtained when the application points are located in straight parallel rows 1.5 k apart and the points are 1.732 k apart in the rows. The 1st application point in the 1st and other odd-numbered rows is located on a line perpendicular to the rows and the 1st application point in the 2nd and other even-numbered rows is made at a distance of 0.866 k from this line. K. D. Jacob

A rapid method for determining k values of nematocides B. G. Chitwood. *Proc. Helminthol. Soc. Wash., D. C.* **6**, 66-70(1939); cf. preceding abstr. and *C. A.* **33**, 4683[1].—The I-type test, devised by Newton, Hastings and Bosher (cf. *C. A.* **31**, 5089[6]), is considered of value in selecting chemicals and detg. dosage rates but not for the detn. of row and hole spacing in plot or field. After a few promising dosage rates are selected, the X- or Y-type tests (described by C.) should be performed. Information so obtained should be applied only under conditions similar to those of the test. **Frames for spacing injections of soil nematocides.** *Ibid.* 70-3. K. D. Jacob

Some factors governing the success of chemical treatment of soil for nematode control. Gerald Thorne. *Proc. Helminthol. Soc. Wash., D. C.* **6**, 60-2(1939).—Granular $Ca(CN)_2$ was applied to a beet-field soil by means of a special applicator attached to the plow beam which dropped the chemical into the furrow just ahead of the plow. The plow depth was 10–12 in. and most of the $Ca(CN)_2$ was applied at that depth. After plowing, the field was harrowed down to a fine mulch and leveled. Applications of $Ca(CN)_2$ at rates as high as 800 lb./acre failed to control *Heterodera schachtii*, apparently because of failure of the HCN to penetrate into the hard subsoil where an important portion of the nematode population was present. Later applications of $Ca(CN)_2$ at a depth of 14-16 in. were also ineffective. K. D. Jacob

The effect of some halogenated hydrocarbons on the eggs of Toxocara canis (Nematoda). John T. Lucker. *Proc. Helminthol. Soc. Wash., D. C.* **6**, 51-7(1939).—Some eggs of *T. canis* became embryonated in cultures initially consisting of 1 part Chlorosol (a com. mixt. of ethylene dichloride 3 and CCl_4 1 part by vol.) or dichloropentane (a com. mixt. of isomers) and 14 parts water. Chlorosol delayed the development of the eggs. Dichloropentane prevented the larvae in embryonated eggs from reaching a normal structure to a greater extent than did Chlorosol. Practically all eggs placed on moist soil in small dishes and exposed to small amts. of Chlorosol or ethylene dichloride, under conditions minimizing loss of vapors from the containers in an initial period of 48–96 hrs., failed to become embryonated or undergo appreciable development and were evidently killed. Practically all embryonated eggs similarly exposed to Chlorosol for 96 hrs. were also killed. Under the same conditions, dichloropentane and CCl_4 were ineffective in preventing embryonation of the eggs, but development was delayed by CCl_4. Dichloropentane was not effective against embryonated eggs under similar conditions. A practical method of confining the vapors closely to the soil must be developed before Chlorosol and ethylene dichloride can be used effectively for killing ascarid eggs on runways of dog and fox kennels. K. D. J.

Progress report on vegetable diseases. X. L. Ogilvie, H. E. Croxall and C. J. Hickman. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 91-7(Pub. 1939); cf. *C. A.* **33**, 7991.—$CuCN_2$, applied to the soil at the rate of 5 cwt./acre, seemed to exert some degree of control of *asparagus rust* caused by *Puccinia asparagi*. Promising results in the control of *celery blight*, caused by *Septoria apii*, were obtained by dusting the seed with either Me Hg phosphate or proprietary prepns. contg Ph Hg acetate or Et Hg chloride. The stand of plants and yield of peas were greatly increased by treating the seed with Cu_2O or with certain org. Hg compds. Increases in germination also resulted from the Cu_2O treatment of seeds of sugar beet, tomato, cucumber and sweet pea. Germination of cabbage, turnip, radish and lettuce was increased by treating the seed with ZnO. K. D. J.

Chemical control of rust of cultivated plants K. Hasselbraluk. *Angew. Botan.* **20**, 366-73(1938), cf. *C. A.* **32**, 5572[8].—Cu sprays were only fairly effective in controlling rust of asparagus, but Bordeaux (Wacker) was fairly effective against rust of snapdragon. α-Naphthol seemed to be a promising dust in the control of rust. Materials added to the soil to render plants resistant to rust were: picric acid (I) and *p*-toluenesulfonamide (II). I and II were tested on cereal. II was tested on mint, mallow and snapdragon; the results regarding control of rust on these plants were either neg. or not conclusive. K. Longrée

Control of kernel smut of sorghum. A. F. El-Helaly *Ministry Agr., Egypt, Tech. Sci. Service, Bull.* No. 233, 22 pp.(1939).—The disease was controlled by mixing the seed thoroughly with Agrosan G at the rate of 2.5–5.0 g./kg. or by treating the seed with 1-2% soln. of Uspulun or Germisan for 15 min. Semesan used at the rate of 5–10 g./kg. of seed also gave good results. The treatments protected the seed against attack by weevils during storage and had no adverse effect on the subsequent germination of the seed and growth of the plants. Susceptibility to the disease was definitely increased by treating the seed with solns. of Cu_2Cl_2 or Cu_2I_2. $HgCl_2$ and Cu_2I_2 treatments had an adverse effect on seed germination and plant growth. Treatments with either CH_2O, $CuSO_4$, Cu nitrate, Cu chloride or Cu acetate did not protect the seed against attack by weevils. In lab. tests the toxicity of S and Cu carbonate toward spores of the causal organism was increased enormously by using soil filtrate instead of distd. water as the germination medium. Spore germination in soil filtrate alone was about half that in distd. water alone. K. D. Jacob

Systematic and automatic warm-water steeping to control loose smut of wheat. G. Howard Jones. *Ministry Agr., Egypt, Tech. Sci. Service, Bull.* No. 220, 12 pp.

(1939).—Nearly complete control of the smut, without injury to seed germination, was obtained by steeping the wheat in water at either 40° for 6–8 hrs. or 43° for 4–6 hrs. Steeping at 41.5° for 6 hrs. is most suitable for practice. An automatic machine for carrying out the warm-water treatment is described and figured. K. D. Jacob

The control of fire blight (Phytophthora infestans) of potatoes. J. K. Thompson. *Kirton Agr. J.* No. 3, 7, 9–11, 13, 15–28(1939).—Regardless of the degree of fineness, dry-mixed $CuSO_4$-$CaCO_3$ dusts contg. 10% or less of Cu did not give satisfactory control of blight. The best, though not complete, control given by dry-mixed dusts was obtained with those contg. 24% Cu. Results obtained with Cu lime dusts prepd. by different methods were inconclusive. K. D. Jacob

The control of damping-off fungi by means of chemicals applied to the soil, with special reference to weak formaldehyde solutions. L. Ogilvie, C. J. Hickman and H. E. Croxall. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 98–114(Pub., 1939).—Of the large no. of chemicals tested, CH_2O was the most effective against the fungi causing damping-off. When it was used at dilns. of 1 200 600 for watering seed boxes after the seed had been sown, it controlled the fungi to a marked extent. CH_2O was used successfully with seeds of peas, tomatoes, cucumbers and sweet peas, but it caused injury to seeds of stocks and certain other ornamentals. Twenty-six references. K. D. Jacob

Experiments with oil spray for the control of the mussel scale (Lepidosaphes pinnaeformis Bché). Y. Ben-Amotz. *Hadar* **12**, 203–6(1939).—Good control was obtained by spraying with 1½ and 2% white oil emulsions. Colin W. Whittaker

An outline of the life history of the hop-vine borer, Gortyna immanis Guenee, with notes on its control. H. A. Gilbert. *Ann. Rept. Entomol. Soc. Ontario* **69**, 107–14 (1938).—*p*-Dichlorobenzene, applied to the soil as a fumigant for control of the borer, was highly injurious to hop plants. K. D. Jacob

Treatment of lemon seeds to prevent molds. M. Zubov. *Sovet. Subtropiki* **1938**, No. 5, 120; *Khim. Referat. Zhur.* **1**, No. 11–12, 72–3(1938).—To prevent growth of *Penicillium* (green and blue mold), the following substances were investigated: borax, Solbar, aqua Laurocerasi, formalin, 40% nitrophenylboric acid, and Granosan. In wet treatment best results were obtained with 5% borax and 5% Solbar. In dry treatment best results were obtained with Granosan and 40% nitrophenylboric acid in the amt. of 5 g./kg. of the seeds. Germination of the seeds was decreased by 10–15% after the wet treatment. No decrease was observed after the dry treatment. W. R. H.

White grubs and pasture deterioration on the Atherton Tableland. D. O. Atherton. *Queensland Agr. J.* **52**, 484–522(1939).—Soils from a grub-infested area had pH values of 4.5–6.0 and patches showing poor growth of crops were assocd. with low pH values (4.4–4.6) and deficiencies of Ca, P, K and Mg. *Analyses of silage crops* (maize, soybean, rice bean, velvet bean and Groit cowpea) grown on the Tableland soils are given. K. D. Jacob

A method for determining deguelin in derris and cubé. Lyle D. Goodhue and H. L. Haller. *Ind. Eng. Chem., Anal. Ed.* **11**, 640–2(1939).—After the rotenone and aq. alkali-sol. material are removed from derris and cubé, the remaining resin is treated with dil. methanolic alkali. The resulting racemic deguelin is crystd. from CCl_4 and weighed as a 1 to 1 solvate. The purity of the solvate is detd. by the Goodhue red color test (cf. *C. A.* **30**, 2690⁹). The deguelin content, as detd. by this method, of 7 samples of derris, 5 of cubé and 1 of timbo varied from 0.25 to 3.92%. The high toxicity to insects of the noncryst. portion of derris and cubé exts., coupled with a generally low deguelin content, suggests the presence of other unidentified compds. that contribute to the toxicity. J. R. A.

Combined washes. Progress report. V. H. G. H. Kearns and H. Martin. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 66–71(Pub., 1939); cf. *C. A.* **33**, 801⁶.—Petroleum oil sprays contg. either dinitro-*o*-cresol (I) or Bu carbitol thiocyanate failed to control aphids that had just hatched from the eggs, but sprays contg. 3% or more of petroleum oil gave an appreciable control of fruit tree red spider (*Oligonychus ulmi*) eggs. When applied to plums before egg hatch, the sprays gave a high control of plum aphis (*A. padi*) and could be applied with safety just before bud burst. Sprays contg. I could not be applied to apples later than the very early green-flower stage without risk of serious injury. Black currants and gooseberries with the flower buds exposed suffered complete loss of crop, but red currants were more tolerant. Grade A tar-oil emulsions (3%) gave complete control of plum aphis and could be applied just before bud burst without causing flower injury. K. D. Jacob

Accident prevention in the use of poisonous spray materials. Hubert Martin. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 145–53(Pub., 1939).—The various methods of accident prevention are reviewed and the precautions legally enforced or voluntarily observed in different countries are compared. K. D. J.

Spray-injury studies. Progress report I. Some observations on the probable causes of lime-sulfur injury. W. E. Berry. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 124–44(Pub., 1939).—Symptoms of lime-S injury are described and the relative susceptibilities of some varieties of common fruit plants are indicated. The penetration of spray materials into the leaf is discussed with particular reference to cuticle permeability and the effect of nutritional and climatic factors. Exptl. results indicated that foliage injury from lime S may be correlated with temp., humidity and sunshine. Max. injury occurred when temp. was high, humidity low and sunshine continuous. Inasmuch as concd. sprays of sucrose and $CaCl_2$ produced little damage compared with lime S, loss of water due to the purely osmotic effect of spray deposits is not alone responsible for spray injury. Detached leaves of Lane's Prince Albert and Laxton's Superb apples exhibited rapid increases in respiration when sprayed with 2% lime S and showed symptoms similar to those observed in the field. Necrotic patches are believed to result from local penetration of spray fluid, but the increase in respiration seems to be due to a more general physiol. effect on the whole leaf. Injury from lime S of the type resulting in leaf abscission may be caused by a gaseous or volatile compd. such as H_2S. Twenty-nine references. K. D. Jacob

The anthelmintic efficiency of "Lentin" against the more important internal parasites of sheep. Grahame Edgar. *Australian Vet. J.* **15**, 172–6(1939).—"Lentin," a stable deriv. of choline, seems to possess a pharmacol. action similar to that of physostigmine. Lentin showed no anthelmintic efficiency on *Haemonchus contortus* and *Trichostronglus colubriformis*, had very little effect on *Oesophagostomum columblanum* and was toxic to sheep in poor condition. Colin W. Whittaker

The efficiency of copper sulfate and carbon tetrachloride against Haemonchus contortus in adult sheep. Hugh McL. Gordon. *Australian Vet. J.* **15**, 118–20(1939); cf. *C. A.* **34**, 159⁹.—One fluid oz. of 4% Cu sulfate soln. is not an effective dose against *H. contortus* in adult sheep but 2 oz. is very effective. Two ml. of CCl_4 in 3 ml. of liquid paraffin is very effective. Colin W. Whittaker

---

Compns. for use as insecticides (U. S. pat. 2,177,197) **26**. Alkylolaminomethylene compds. [for insecticides] (U. S. pat. 2,169,737) **10**.

Use of phenothiazone as a fungicide. Marion C. Goldsworthy (to the people for free use). U. S. 2,177,198, Oct. 24. Phenothiazone may be used with lime, bentonite, water, etc.

Insecticides. Donald L. Vivian (to the Secretary of Agriculture of the U. S. A.). U. S. 2,173,386, Sept. 19. In insecticides such as those for fruits or vegetables, use is made of hydrazobenzene or other compds. of the general formula $PhNHNHC_6H_4R$ where R represents H, methyl, ethoxy or halogen.

Insecticidal oil emulsions. Paul R. Jones (to Shell

Development Co.). U. S. 2,177,434, Oct. 24. A plant spray mineral oil is emulsified with water by use of a petroleum sulfonate and cottonseed oil from which the free fatty acids have been removed by treatment with a caustic alkali.

Insecticidal compositions. Benjamin Collie, Wm. H. Davies, Wilfred A. Sexton and Imperial Chemical Industries Ltd. Brit. 507,221, June 12, 1939. The compns. comprise as an active ingredient a *N*-alkylbenzothiazolethione. These compds., e. g., *N*-ethylbenzothiazolethione, may be prepd. by heating the corresponding 2-benzothiazyl alkyl sulfide alone or with Br, I or an alkyl bromide. The active ingredient is mixed with an inert pulverulent carrier to which a H_2O-absorbent or dust-binding agent may be added, or may be suspended or emulsified in H_2O or in H_2O and an org. liquid to which spreading, emulsifying and other agents may be added. Other insecticidal substances may also be added.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Yeasts in the production of alcohol from wood. I. A. Mazilkin. *Microbiology* (U. S. S. R.) **7**, No. 5, 611–81 (1938); *Khim. Referat. Zhur.* **2**, No. 4, 66(1939).—Yeast (the plant mash cultured 4 v) which is added to the hydrolyzate of the wood very soon shows signs of poisoning and is replaced by smaller forms of yeast by means of which the hydrolyzate is fermented. The fine yeast is a sep. form belonging to *Saccharomyces exignus*. If several races of the yeast sepd., No. 2 was the predominant kind. It ferments the hydrolyzate rapidly and multiplies rapidly, but is not sufficiently stable. The yeast 4 v belongs to *Saccharomyces cerevisiae*, it resembles the race *XII*, but its fermenting power is small. It is unsuitable for the production of alc. from wood material. The yeast of the race *L* was sepd. from the vats of continuous fermentation in which mineral salts are added to the hydrolyzate. It resembles *Saccharomyces chevalieri Guill.* In contrast to the yeast No. 2 it yields an insignificant percentage of dead cells during prolonged cultivation in the hydrolyzate. It is intermediate in rate of fermentation. W. R. H.

The traces of copper and iron in alcohol. J. Knop and J. Malcher. *Chem. Obzor* **14**, 209–12(1939).—A spectrum of the residues from raw alcs. showed the elements Al, Ca, Cu, Fe, K, Na, Mg, Mn and Si. The Fe lines exceeded those of Cu in intensity. For the Cu detns. neutralize 25 cc. of raw alc. with NaOH, mix with 25 cc. H_2O, add 5 cc. of a diphenylcarbazide reagent (0.1 g. of diphenylcarbazide in 50 cc. EtOH and 50 cc. C_6H_6), dil. to 100 cc. with C_6H_6, shake and allow the mixt. to stand quietly for several hrs. Remove the colored C_6H_6 layer and compare it to a $Cu(NO_3)_2$ in EtOH soln. contg. 0.00145 0.00029 mg. Cu per cc. In 9 specimens of raw alc. prepd. in Czechoslovakia the Cu content ranged from 0.2 to 5.2 mg. per l. Refined alc. contained 0.001 mg. Cu per l. For the Fe detns. take 25 cc. of neutralized raw alc., add 0.25 cc. of concd. HCl, 0.25 cc. of concd. HNO_3 and 5 cc. of a 10% KCNS, dil. to 100 cc. with water, and allow to stand for 1 hr. Compare the colored soln. with a standard $FeCl_3$ soln. contg. 0.002 mg. Fe per cc. In 8 specimens of raw alc. prepd. in Czechoslovakia the Fe content ranged from 0.7 to 42.9 mg. per l. Refined alc. contained 0.02 mg. Fe per l. The presence of Fe in the ratio Fe:Cu::5:1 did not interfere with the Cu detns. Elec. cond. detns. confirmed the analyses. In the residues from 9 different distilleries the Cu content ranged from 7 to 21 mg. per l. and the Fe content ranged from 3 to 12 mg. per l., the Cu content exceeding that of Fe in all residues. The method enables a study of the *corrosion of stills* and an evaluation of the *keeping qualities of motor fuel*, i. e., catalytic effect of Fe and Cu upon the formation of resins and unsatd. hydrocarbons. Frank Maresh

Formation of fusel oil during alcoholic fermentation. II. M. I. Zalesskaya. *Microbiology* (U. S. S. R.) **7**, No. 5, 546–64(1938); *Khim. Referat. Zhur.* **2**, No. 4, 66–7 (1939); cf. *C. A.* **33**, 5980[2].—The use of tech. leucine lowered the yield of fusel oil to 0.12%; with pure leucine the yield was 0.14%. The most energetic formation of fusel oil coincides with the beginning of the main fermentation of sugar, when the multiplication of yeast and the deamination of leucine are nearly concluded, in the period of from 24 to 48 hrs. The greater the amt. of the fermented sugar the greater the yield of fusel oil. On lowering the amts. of added yeast (3 million cells/cc.) the formation of fusel oil takes place slowly and continues uniformly until the fermentation is concluded, but the yield is greater (0.23%). With a larger amt. of yeast (30 million cells/cc.) the formation of fusel oil stops rapidly (in 36 hrs.) simultaneously with the main fermentation of sugar and the yield of fusel oil is smaller (0.19%). The splitting of leucine by yeast takes place very rapidly; within 12 to 24 hrs. up to 70% of the leucine is consumed.

Chemical control of distilleries. Jose Martinez Dalman. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 214–26.—Elementary. O. W. Willcox

Applications of capillary analysis. I. Detection of artificial coloring matter in red wines. Carlo Ferrari. *Ann. chim. applicata* **29**, 367–73(1939).—The method of K. Fajans depending on the adsorbing power of Ag halides is used. Twenty-five cc. of wine is acidified with 5 cc. of dil. HNO_3 (1 3), 10 cc. of 0.1 *N* $AgNO_3$ is added, and then 3–4 cc. of 0.1 *N* KI, drop by drop. If the color is natural, the AgI is yellow, whereas, if an acid dye has been used the ppt. is violet-colored. If the reaction is carried out on a filter paper, a semimicrotest can be made. A. W. C.

Application of hydrogen peroxide to brewing. I. Destruction of the odor of putrefied sake by hydrogen peroxide. Masakazu Yamada. *J. Agr. Chem. Soc. Japan* **15**, 699–700(1939); cf. *C. A.* **33**, 4368[8].—When 0.001 part of 35% H_2O_2 was added to 1 part of putrefied sake and it was kept at ordinary temp. for 4–5 days, the smell was completely removed. **II. The action of catalase at various stages in sake brewing.** *Ibid.* 700–2.—The action of catalase was strongest in the aq. ext. of koji. It decreased gradually with the progress of brewing. It declined suddenly after the pasteurization of sake. It decreased more or less by putrefaction. **III. Influence of alcohol and temperature upon the catalase of sake.** Masakazu Yamada and Syōzō Masui. *Ibid.* 702–4.—The catalase in sake could not be completely destroyed by pasteurization, while the diastase lost its activity by heating at 45–60°. The catalase in the koji ext. was destroyed by heating at 80°, while that in sake at 70°. It may be due to the presence of alc. in sake. **IV. Destruction of catalase in sake by hydrogen peroxide.** Hisao Matui and Masakazu Yamada. *Ibid.* 704–8.—Sake was prevented from putrefaction in the presence of a small amt. of H_2O_2. The catalase in sake should be first destroyed by the addn. of H_2O_2, and then the excess of H_2O_2 was available for sterilization. One thousandth part of 35% H_2O_2 was decompd. by the

catalase in sake within 24 hrs. When sake was heated at 50° and 0.001 part of 35% H_2O_2 was added, the catalase in sake was inactivated. V. **The action of hydrogen peroxide on biacetyl, acetoin and butylene glycol.** *Ibid.* 708–10.—When H_2O_2 was added to remove the smell of putrefied sake, acetoin or 2,3-butylene glycol in the putrefied sake could not be destroyed, while biacetyl was oxidized to AcOH. VI. **Effect of hydrogen peroxide on the growth or multiplication of microörganisms.** *Ibid.* 819–20.—The multiplication of sake yeast and distillery yeast was retarded in the koji ext. contg., resp., 0.028% and 0.024% of H_2O_2, while *Aspergillus oryzae* was resistant even to 0.1% of H_2O_2. VII. **Complete prevention of putrefaction of sake by hydrogen peroxide.** Masakazu Yamada, Hisao Matui and Tokuitiro Ohasi. *Ibid.* 820–5.—The catalase in sake was destroyed by heating at 55° and H_2O_2 was added. Four mg. of H_2O_2 remaining in 100 cc. of sake was sufficient to prevent the putrefaction, even when sake was dild. with H_2O. An excess of H_2O_2 spoiled the taste of sake. VIII. **Application of hydrogen peroxide to the preservation or the refining of beverages or brewages.** Hisao Matui and Masakazu Yamada. *Ibid.* 826–30.—When H_2O_2 was added to soy for preservation, it was decolorized giving a bad smell. It may be due to the oxidation of amino acids into aldehydes. H_2O_2 was gradually decompd. by catalase in the soy. Hence it was quite inadequate to use H_2O_2 as the rectifying agent or antiseptic for the soy. When H_2O_2 was added to vinegar, the smell of bacteria or biacetyl was removed. The addn. of 0.001–0.004 part of 35% H_2O_2 to "calpis," tomato catsup, syrup of coffee, soap, evapd. milk, bean curd or vermicelli was successful. Also in *Bull. Agr. Chem. Soc. Japan* **14**, 58–60(1938); **15**, 115–17(1939)(in English). Y. K.

Absorption of bromine by mash as a measure of quality. K. Sotomn. *Spirto-Vodochnaya Prom.* **1938**, No. 6, 35–6; *Khim. Referat. Zhur.* 2, No. 2, 130(1939).—Br absorption is a much more accurate measure of quality in mash than is I absorption. The two methods are described, with comparative results. W. R. Henn

Determination of reducing sugars in wort and in mash by means of photoelements A. Egorov. *Spirto-Vodochnaya Prom.* **1938**, No. 9, 38–40; *Khim. Referat. Zhur.* 2, No. 4, 82–3(1939).—In the detn. of reducing sugars, Cu^{++} is detd. photocolorimetrically before and after the reduction, by means of a Cuprox element and a yellow-orange light filter. W. R. Henn

The determination of the electrical conductivity of yeast from the viewpoint of the manufacturer. V. Jonáš, R. Briess and M. Kninek. *Chem. Obzor* **14**, 169–77, English summary(1939).—Elec. cond. detns. of yeast suspensions made in the yeast plant in the manner of Šandera (*C. A.* 33, 7326[4]) show that freshly prepd. com. yeast suspensions have a relative cond. of 12 which remains const. for 3–6 days at 18–25°, that the elec. cond. of fresh com. yeasts from other factories in Czechoslovakia ranged from 14 to 28, that water used in the prepn. and for the washing of yeasts had a relative cond. of 9, that water from the presses and water from between yeast cells had a relative cond. of 12. For 1st generation yeast cells used for cultures, the relative cond. ranged from 24 to 45. Yeasts stored in packages which dried at the terminal period showed the following relative cond. on the resp. days (1) 16, (3) 18, (6) 20, (15) 28, (24) 46 and (30) 58; for yeast which liquched during storage the relative cond. during the following days of storage was (1) 17, (3) 18, (6) 20, (15) 40, (20) 68 and (22) 161. From factory experience a low cond. value indicated a good preservation in storage, a relative cond. of 70 meant the beginning of autolysis, a value in the range 110–140 was accompanied by a smeariness, and at 160 liquefaction began. At 35° the relative cond. reached a value of 100 in 24 hrs. and ranged from 180 to 240 at the beginning of liquefaction. Yeasts with a low elec. cond. had the highest fermenting powers and produced the best doughs. A low ash content in yeast cells correlated with a low cond.; the total N content of yeast cell bore no relation to the elec. cond. At 35° during autolysis the ratio of relative cond. to the percentage of dead yeast cells was on the following days (1) 17:2, (2) 30:9, (3) 67:14, (4) 88:14, (6) 105:20, (8) 200:25, (10) 412:48 and (13) 1135:78. All electrolytes were released by boiling yeast cells for 30 min.; further boiling did not increase the cond. above the range 150–190. The elec. cond. of a sucrose soln. fermented by yeast rose from 10 to 12 during the fermentation. Yeasts with a good appearance had a low cond.; yeasts with a dark color had a high cond. For abs. units the relative cond. values should be maltiplied by 1.58×10^{-5} ohm^{-1} cm.$^{-1}$.

Concn. and examn. of bios required by English brewery top fermentation yeast (Rainbow, Bishop) **11C.**

Denaturing alcohol. Leo M. Christensen (to Chemical Foundation, Inc.). U. S. 2,176,208, Oct. 17. An arrangement of app. is described, and a method of producing a denatured EtOH to produce a power alc. fuel which involves treating a primary amine such as monoamylamine with $CHCl_3$ and with NaOH in the presence of the EtOH which is to be denatured, co-distg. and co-condensing the volatile and condensable reaction products together with the excess alc. and blending the condensate thus produced with additional quantities of alc.

Denatured alcohol. Louis J. Figg, Jr. (to Eastman Kodak Co.). U. S. 2,176,489, Oct. 17. Diphenyl ether 0.5–5% is used as a denaturant, alone or together with other denaturants. U. S. 2,176,491 relates to the use of about 0.5–5% of formamide as a denaturant. U. S. 2,176,490 (Louis J. Figg, Jr. and James W. Rhea, joint inventors; to same assignee) relates to the use of about 0.5–5% of dichloromethyl ether or dichloroethyl ether for denaturing alc. U. S. 2,176,492 relates to the use of a mixt. of $NaNO_2$ and butyl stearate for inhibiting corrosion, in alc. antifreeze compns.

Device for aerating liquids, as in yeast manufacture. James Lockey (to Standard Brands Inc.). U. S. 2,176,558, Oct. 17. Use is made of a device which may comprise a pipe having suitably disposed escape passages, and a tightly fitting enveloping pipe having a spirally running slit therein forming escape passages communicating with the first named pipe, the enveloping pipe having a coefficient of expansion differing from that of the enveloped pipe and adapted to control the discharge from the escape passages of the first named pipe as well as the discharge from the spirally running slit of the enveloping pipe, and a layer of wire wound to form a pipe about the enveloping pipe, the spirally running slit and the spacings between the windings of the wire being of a width insufficient to permit the entry of particles to the escape passages. Cf. *C. A.* 33, 4738[3].

Nails and nail changes. I. Investigation of nail lacquers and their components. Henry Silver and Bernard Chiego. *J. Investigative Dermatol.* 2, 361–74(1939).—A study of the compn. of fingernail lacquers with toxicol. and sensitization tests on guinea pigs and patch tests on human subjects. Philip D. Adams

Preparation of ampoules of calcium levulinate. Lorenzo Bracaloni. *Boll. chim. farm.* **78**, 457–9(1939); cf. *C. A.* 33, 7481[8].—Ca levulinate hydrated (I) and anhyd. contains 13.00–13.10% and 14.10–14.20% Ca and this Ca content is superior to that found in the corresponding gluconates and camphorsulfonates. A 5% soln. of I in doubly distd. H_2O has a cryoscopic p. −0.78° and pH 7.6. The addn. of 5 cc. *N* HCl to 1 l. of soln. shifts the pH to

6.2–6.6. A detailed procedure for the prepn. of 10 l. of 5% **I** as a brilliant limpid soln. suitable for hypodermic and intravenous injection is given. Sterilization of the ampouled soln. in neutral glass at 100° for 1 hr. caused no perceptible change in the properties of the soln. which gave no local or general reactions on intravenous injection in animals and in human subjects. C. R. Addinall

Italian ephedras. Carlo Alberti. *Boll. chim. farm.* **78**, 477-81(1939).—A study of the ephedras of Sardinia and Sicily showed that *E. vulgaris*, *fragilis*, *altissima* and *procera* have low alkaloidal content (0.36, 0.03, —, 0.12%) and that they contain predominantly the pharmacologically inactive pseudoephedrine. The problem of using *E. vulgaris* as a national source of ephedrine resolves itself into devising methods for the economical extn. of the alkaloid and its conversion to ephedrine. C. R. A.

Preparation of aqueous solutions of folliculin for hypodermic use. Antonio Mossini. *Boll. chim. farm.* **78**, 482 3 (1939).—A mixt. of 0.05 g. folliculin, 1 g. $N(CH_2CH_2OH)_3$ and 95 cc. of $HOCH_2CH_2OAc$ is heated with stirring to complete soln. and cooled. Diln. with doubly distd. H_2O gives a limpid soln., unstable to light and air, which is suitable for ampouling in colored ampoules under an inert gas. Such ampoules can be sterilized at 100° without loss of activity and provide solns. suitable for intravenous use. C. R. Addinall

Vitamin A and D potencies of liver and intestinal oils of halibut (Hippoglossus hippoglossus). L. I. Pugsley. *J. Fisheries Research Board Can.* **4**, 396–404(1939).—In northern British Columbia halibut, size seems to be the most important factor detg. the vitamin A content. Vitamin A varies inversely with the percentage of oil in the liver, whereas the vitamin D content appears to be unrelated to the size of the fish or to the vitamin A content. Oil from the heads and trimmings is low in both vitamins. 5 Halibut with 5.03% viscera contain 1.21% liver and 2.15% intestines, which yield 17.1% and 3.6% of oil, resp. Liver, liver oil, intestines and intestinal oil contain 4100, 35,000, 2300 and 80,000 blue units of vitamin A per g., resp. Seasonal variations of these various yields, their vitamin A and D potencies and the I no. of the oils are tabulated. C. R. Addinall

Vitamin A and D potencies of liver and intestinal oils of gray cod (Gadus macrocephalus). L. I. Pugsley. *J. Fisheries Research Board Can.* **4**, 405 8(1939); cf. *C. A* **33**, 2357[4].—A year-round study of the seasonal variations of the liver and intestinal content of *G. macrocephalus*, a species of true cod present in the coastal waters of British Columbia and Alaska, showed a definite increase in the liver content (4% in August) during the fall and winter months (prespawning period) accompanied by a rise of the liver-oil content (12.8% in October) and a decrease in the vitamin A content (1100 blue units per g. in October). A similar fall in the vitamin D content (125 international units in November) was noted. The vitamin A and D contents (6500 and 365) and the unsaponifiable matter of the liver oil were above the av. for gadids. The intestines (2.4%) yielded less oil than the liver (31.2%) but the oil was relatively high in vitamin A (16,000 blue units per g.) and low in D (35 international units per g.). Summaries of these seasonal variations are tabulated. C. R. A.

Review of Chinese materia medica during the last decade. Bernard E. Read. *Natl. Med. J. China* **25**, 3–14(1939). Wm. H. Adolph

Chemical properties of some Chinese herbs. Heng-Pi Chu. *Natl. Med. J. China* **25**, 15–54(1939).—A review of 24 important herbs used in medicine. W. H. Adolph

The preparation, toxicity and bactericidal activity of methenamine mandelate. Glenn L. Jenkins, Laurine Jack and Charles H. Drake. *Pharm. Arch.* **10**, 81-5 9 (1939).—The prepn. of the compd. is given. The compd., $C_{14}H_{20}O_3N_4$, m. 129.2–129.5°, is readily sol. in H_2O, slightly sol. in EtOH, practically odorless and has a sweetish taste, pH (10% aq. soln.) 4.5. It is toxic to rats on intraperitoneal injection and nontoxic on oral administration to rabbits and it is bactericidal in urine *in vitro* at pH levels of 5.5, 6.0 and 6.5. H. M. Burlage

Adaptation of assay methods for some N. F. preparations. IV. Ointment of mild mercurous chloride. Robert Tzucker and Wm. B. Baker. *Pharm. Arch.* **10**, 85–7 (1939); cf. *C. A.* **33**, 9542[1].—The following adaptation of the U. S. P. XI method for the assay of HgCl is offered: Place about 2.5 g. of the ointment in a 250-cc. tared, glass-stoppered flask and weigh accurately. Add 100 cc. $CHCl_3$, stopper, and shake gently until the ointment base is dissolved. Filter the mixt. and wash the residue with small portions of $CHCl_3$. Place the filter paper and contents in the glass-stoppered flask, add about 25 cc. H_2O and mix well. Add 50 cc. 0.1 *N* I_2 and 5 g. KI dissolved in 10 cc. H_2O. Stopper the flask, allow the mixt. to stand with occasional shaking until complete soln. has taken place, and then titrate the residual I_2 with 0.1 *N* $Na_2S_2O_3$, using starch test soln. as an indicator. Each cc. 0.1 *N* I_2 = 0.02361 g. HgCl. The following standard for the N. F. ointment is recommended: It contains not less than 29% and not more than 31% HgCl. H. M. Burlage

Capsicum from Italian Somaliland. (Capsicum frutescens L.) Carlo Alberti. *Ann. chim. applicata* **29**, 392-402(1939).—Two types of capsicum are generally recognized: the annual, *Capsicum annuum* L., and the perennial, *Capsicum frutescens* L. Somaliland furnishes the perennial. Its therapeutic properties are equal to those of imported varieties. A. W. Contieri

Evaluation and proper storage of some of the principal pharmaceutical preparations (tinctures, fluidextracts) János Ragettli. *Magyar Gyógyszerésztud. Társaság Értesitője* **15**, 521-67(1939).—Digitalis tincture can be stored for years without any considerable changes in the dark and cold, provided it is kept in small, dark-colored glass bottles, completely filled, and sealed with paraffin. A criterion of proper storage is const. pH. The degree of decompn. of glucosides is shown by the fluorescence of digitoxose. Infusions can be stored in a similar manner for a long time. S. S. de Finály

Evaluation of digitalis by means of Rana esculenta. Aranka Stasiak. *Magyar Gyógyszerésztud. Társaság Értesitője* **15**, 568-79(1939). —*Rana esculenta* gave values identical with those obtained on *Rana temporaria* or *pipiens*, and the curves were similar to the curves shown by English and Danish investigators. The evaluation of digitalis powders may be calcd. either on basis of the relative sensitivity test curves or by detg. the LD_{50} value according to Møller (*C. A.* **30**, 5364[4]) on basis of single investigations Parallel detns. made during the period 1937–39 showed deviations not greater than 10% in the values obtained by the 2 methods. S. S. de Finály

Aromatic Portuguese plants. II. Lavandula pedunculata Cav. Aloisio Fernandes Costa. *Noticias farm.* (Portugal) **5**, 438-56(1939). - The plant grows wild in Portugal 7 The fresh flower heads yield 0.21% of essential oil, d_4^{15} 0.9354, $[\alpha]_D^{15}$ 19°57′, n_D^{15} 1.46913. It contains ketones 59.5%, free alcs. calcd. as borneol 11.63% and esters calcd. as bornyl acetate 3.28%. Pinene, camphene, camphor and cineole are also present; thujone and linalool absent. The oil resembles oil of *Lavandula stoechas* L. L. E. Gilson

Preservation of insulin in solution and in substance and modifications during this period. Raffaele De Blasi and Umberto Gueli. *Arch. farmacol. sper.* **68**, 123-33(1939) —Various com. prepns. of insulin were kept for 6–7 yrs. and were apparently little affected during this period. Helen Lee Gruehl

Chemical evaluation of the preparations from the valerian root. S. E. Babich. *Farmatsiya* **1938**, No. 4, 7-11 *Khim. Referat. Zhur.* **2**, No. 4, 81(1939).—The quality of valerian root was detd. from the amt. of acids present To 10 g. of sample add 50 cc. of distd. water and distil with steam for 1.5 2 hrs. Titrate the distillate. For the detn. of the combined acids, after the titration add 20 cc. of a 0.1 *N* alkali, evap. to 20–30 cc., transfer to a flask, add 20–30 cc. of 70° alc., heat on a sand bath for 1 hr and titrate excess alkali. To prepare a concd. infusion, add 50 cc. to 100 g. of the finely cut root, let stand for 1–2 hrs., transfer to a percolator and percolate (according to the pharmocopeia) with an amt. of water sufficient to give

400 cc. of percolate. **Distil the residue with steam to a** 100 cc. vol. of the distillate. Add the distillate to the previously obtained 400 cc., filter through cotton and sterilize. The amt. of the acids in the concd. infusion is 2.5-2.7%. W. R. Henn

Microchemical reactions of cocaine. M. D. Shvalkova. *Farmatsiya* **1938**, No. 5, 9–12; *Khim. Referat. Zhur.* 2, No. 4, 81(1939).—Reactions of cocaine with a 5% soln. of $K_2Cr_2O_7$ acidified with HCl, with chlorauric acid, with chloroplatinic acid and with $KPbI_3$ are little sensitive or too little specific and are much inferior to the reaction for cocaine with $KMnO_4$. W. R. Henn

Determination of sulfur and chlorine in albichthol. E. I. Chukhina. *Farmatsiya* **1938**, No. 6, 21–3; *Khim. Referat. Zhur.* 2, No. 4, 81(1939).—Albichthol (cf. *C. A.* **28**, 6243[6]) has several advantages over ichthyol, in place of which it is used. It is transparent, almost colorless, has a specific odor, is easily sol. in alc., lanolin, petrolatum, and vegetable and mineral oils, and forms a fine emulsion with water. Its therapeutic action is greater than that of ichthyol. During refining it is treated with chlorinated lime and, therefore, contains about 2–3% of Cl. The content of S is 9–15%. S and Cl are detd. according to the method of Wirth and Stross (*C. A.* **27**, 2288). W. R. Henn

Essential oil in leaves of camphor basil. M. V. Tsarev. *Farmatsiya* (*Vsesoyuz. Inst. Lekarstvennykh Rastenii, Sekt. Khim.*) **1938**, No. 3, 27–33; *Khim. Referat. Zhur.* 2, No. 4, 61(1939).—Essential oil was detd. by the method of Ginzberg (cf. *C. A.* **27**, 372), in leaves cut every 2 hrs. The surface area of the leaves was 17,800 sq. m. per hectare. All essential oil can be obtained in 5–6 days. The loss of essential oil per hectare of the plantation can reach 13 kg./day, depending on the meteorological conditions. The plants do not use the essential oil for their growth. Light is not directly involved in the formation of the essential oil, but serves as a source of energy for the formation of the primary products of photosynthesis; oil formation is a secondary process. W. R. Henn

The essential oil of Trachyspermum copticum L. N. I. Ibragov. *Farmatsiya i Farmakol.* **1938**, No. 4, 33–6; *Khim. Referat. Zhur.* 2, No. 3, 133(1939).—A sample of the essential oil of *Trachyspermum copticum* L. contained approx. cymene 50%, dipentene and α-terpinene 25% thymol 24% and carvacrol 1%. Thus the oil is of high quality because the thymol contains very little carvacrol and cymene can be transformed into thymol by oxidation. W. R. Henn

Advances in thiamine research. Aaron Arnold and F. D. Baird. *Am. J. Pub. Health* **29**, 1344–9(1939).—Forty-nine references. J. A. Kennedy

Dete mination of iodine in thyroid and its preparations by cerate oxidimetry. Wayne W. Hilty and Dale T. Wilson. *Ind. Eng. Chem., Anal. Ed.* **11**, 637–9(1939).—NaI formed from thyroid gland or tablets by fusing with Na carbonate can, after filtering off carbonaceous residue, be titrated in 2 *M* HCl with 0.005 *N* ceric sulfate (*o*-phenanthroline ferrous sulfate indicator). Percentage deviation from theory of this method applied to a KI-lactose mixt. was 0.1 that of U. S. P. XI. J. McAfee

The assay of officinal diastase; the influence of various factors. The amylolytic titration. J. Langlois and Ch. Morin. *Bull. sci. pharmacol.* **46**, 353–64, 415–36(1939).—The general properties of diastase and the various methods of assay are discussed. The method of the French pharmacopea was used. When NaOAc buffer was added it was found that the optimum of activity lies between pH 5 and 6. The temp. optimum is 55°. The percentage of 10 g. starch split within 1 hr. by 40 mg. diastase is for wheat starch 42.3, corn 45, common potato starch 47.5 and pure potato starch 49.5. The time of boiling the starch may vary from 1 to 60 min. without influencing the results. Excess of starch does not modify materially the quantity hydrolyzed, but very large excess prevents liquefaction and makes the detn. impossible. The hydrolysis proceeds to about 50% at a linear rate. Hydrolyzing for 1 hr. is not excessive. **Activation by glycine or glutathione could not be observed: Cu has a strongly inhibiting action which** is noticeable at 25.4 γ, reduces the hydrolysis to ½ at 170 γ and increases in linear proportion to 250 γ; Ni must be added in quantities from 5.5 to 500 mg. to produce similar inhibition; Zn up to 50 mg. and Ca from 407 mg. to 3.82 g. Glutathione and cysteine (100 mg.) abolish the effect of Cu; glycine is not quite as efficacious. Ascorbic acid seems rather to increase the effect of Cu. The method of the French pharmacopea used with due regard to the results of these expts. gives reliable results. The ratio (starch transformed into maltose)/(diastase used) should be at least 100, a limit easily exceeded by most diastase prepns. The procedure of assay is described in detail. A. E. Meyer

The action of local anesthetics on the plant cell. II. The quantitative action of *p*-aminobenzoyldiethylaminoethanol on the cell content of Ascoidea rubescens (Brefeld). The effect of the acid. Jean Régnier and André Quevauviller. *Bull. sci. pharmacol.* **46**, 365–6(1939); cf. *C. A.* **33**, 8241[5]. A high concn. of OH ions is favorable to the action. The phenylpropionate is generally more active than the citrate, but at pH 7.4 both salts and the HCl salts have almost the same activity. A. E. Meyer

The preparation of morphine from dried poppy capsules. André Goris. *Bull. sci. pharmacol.* **46**, 376–87(1939).—A review on newer publications. A. E. Meyer

Importance of impurities in diethyl ether used for narcosis. I. Acetaldehyde. Lennart Gisselsson and Gunnar Lindgren. *Acta Chir. Scand.* **83**, 45–73(1939).—Expts. made on mice with ether to which 0.5% AcH was added revealed no effect on the time of onset of anesthesia but 1% caused a significant delay. Expts. on guinea pigs likewise showed no change in the time of onset of anesthesia when 0.1–0.5% AcH was added to the ether. Expts. with rabbits revealed no effect of admixt. of AcH to the ether, judged by the time required for the disappearance of corneal and pupillary reflexes or for the cessation of breathing. With 1% AcH the time required was prolonged. Detn. of ether in the blood 15 min. after the onset of anesthesia showed the same concn. whether pure ether or ether-AcH mixt. was used. In rabbits the rate of respiration was somewhat greater where a 0.5% AcH-ether mixt. was used, but in deep anesthesia the respiration rate was the same. With a 1% mixt. the respiration rate was somewhat lower than with pure ether. The vol. of expired air during 15 min. of narcosis was 3905 ± 318 cc. per kg. for the 1% mixt. and 4570 ± 477 cc. per kg. for the 0.5% mixt. as compared with 4450 ± 409 cc. per kg. with pure ether. No disturbances or irregularities in respiration could be observed when the AcH did not exceed 0.5%. No effect was found on the heart nor on arterial or venous pressure with mixts. up to 1%. S. Morgulis

Pharmacognostic study of the leaves of Hamamelis species II. Yutaka Yosida. *J. Pharm. Soc. Japan* **59**, 656–9(in German, 246–7)(1939); cf. *C. A.* **34**, 856[8].—The tannic acid content of the leaves of *Hamamelis* species ranged from 2.27 to 9.47%. F. I. Nakamura

The role of Burow's solution in dermatology. Frank C. Combes. *N. Y. State J. Med.* **40**, 37–41(1940).—Liquor Burowi, an N. F. prepn. of $Pb(C_2H_3O_2)_2$, $Al_2(SO_4)_3$ and water, is recommended for its beneficial buffer, astringent, antiphlogistic and antiseptic action on the inflamed integument. A revision of the N. F. VI method of prepg. this soln. is suggested, i. e., the inclusion of excess $Al_2(SO_4)_3$ to ensure pptn. of all the Pb. J. Pinchack

Tobacco products. II. Constantin Pyriki. *Z. Untersuch. Lebensm.* **78**, 162–79(1939); cf. *C. A.* **30**, 1177[3].—Results are given on content of nicotine, nicotine N, protein, ammonia, ammonia N, residue N, total N, ash, reducing substances before and after hydrolysis, polyphenols before and after hydrolysis, and resins and waxes. These materials were divided into favorable and unfavorable materials and the ratio between the 2 groups was used as a measure of quality. In general, the quality rose with the price of the product. The pH and Schmuck coeff. of the tobaccos are also tabulated. M. M. Piskur

Tobacco investigations. II. Difference between vital and nonvital harvested tobacco leaves after drying. Adolf Wenusch. *Z. Untersuch. Lebensm.* **78**, 179–84(1939);

cf. *C. A.* **33**, 7491[7].—The extn. of fine powd. tobacco with ether, alc., water, dil HCl and dil. lye yields an insight to the biol. growth state of the leaves. The amt. of aq. ext. depends upon the condition under which the tobacco is grown. Hunger-grown (Oriental) tobacco yields small aq. exts. Vital leaves contain more protein and more degradation products of proteins and less cellulose than those that have lost their vitality. M. M. Piskur

Potency of certain commercial hormone preparations. II. Fred E. D'Amour. *Endocrinology* **26**, 88–92(1940); cf. *C. A.* **32**, 5158[7].—Estrogens in oil, for parenteral use, are uniformly potent. Aq. estrogens deteriorate and do not contain the labelled potency. Estrogens for oral use should be assayed orally. Progestin prepns. in oil are uniformly potent, aq. prepns. are not. Growth hormones deteriorate on standing. Most cortin prepns. are potent and contain the expected activity. Felix Saunders

Biological potency of International Standard Chorionic Gonadotropin. Fred E. D'Amour and Marie C. D'Amour. *Endocrinology* **26**, 93–6(1940).—International Standard Chorionic Gonadotropin was assayed by 5 methods. The biol. potency of the international unit, 100 γ of this prepn., was detd. The combination of uterine wt. and vaginal cornification methods, the absence of estrin having been assured, represents the most desirable method for the use of this material in the assay of gonadotropic substance originating from human pregnancy urine. Felix Saunders

The evaluation of crude drugs. V. Microscopical examinations. T. C. Denston. *Chem. Products* **2**, 161–3, 146(1939); cf. *C. A.* **33**, 8919[8].—The use of glycerol, chloral hydrate soln., phloroglucinol soln. and HCl, Sudan red or tincture of alkanet, alk. soln. of corallin and ruthenium red soln., resp., for the examn. of a powd. drug is discussed and the general diagnostic microscopical characters are given of powd. drugs belonging to different groups. Leopold Scheflan

Analysis of chaulmoogra oils. IV. Hydnocarpus anthelmintica oil. V. Taraktogenos kurzii (chaulmoogra) oil. Howard I. Cole and Humberto T. Cardoso. *J. Am. Chem. Soc.* **61**, 3442–5(1939); cf. *C. A.* **33**, 8921[6].—By use of previously described methods the following percentage compn. of the fat acids of *Hydnocarpus anthelmintica* (I) and *Taraktogenos kurzii* (II) oils were detd.. hydnocarpic acid 67.8, 34.9; chaulmoogric acid 8.7, 22.5; gorlic acid 1.4, 22.6; oleic acid 12.3, 14.6; palmitic acid 7.5, 4.0; lower homologs of hydnocarpic acid 0.1, 0.4; loss 2.2, 1.0. The oils (I and II) showed the following characteristics: d_{25}^{25} 0.952, 0.952; free fat acid (as percentage of oleic) 2.9, 1.3; sapon. no. 203.3, 200.6; I no. (Hanus) 89.2, 101.5; α_D^{25} 49.7, 49.8; n_D^{25} 1.4772, 1.4790; unsaponifiable matter, % 0.50, 0.29. C. J. West

Analysis [of pharmaceuticals] for traces of metallic impurities (Hess, *et al.*) **7**. Enzyme investigations during drying of green tobacco (Bartá) **11A**. New products of 1939—in medical chemistry (Howe) **13**. Peroxidic products (germicides, fungicides) (U. S. pat. 2,176,407) **10**.

Therapeutic gold compounds of acylalkylglucamide disulfides. Max Bockmühl and Gustav Ehrhart (to Winthrop Chemical Co.). U. S. 2,174,412, Sept. 26. See Can. 382,217 (*C. A.* **33**, 7962[3]).

***N*-Lower-dialkyl-coumarin-3-carboxamides.** Otto Dalmer and Fritz von Werder (to Merck & Co., Inc.). U. S. 2,170,127, Aug. 22. Sedative compds. of but slight toxicity are produced by various reactions, preferably by treating coumarin-3-carbonyl chloride with a lower dialkylamine. Coumarin-3-carboxdimethylamide m. about 144–5°; the diethylamide m. about 77°; the methylethylamide m. about 108–9°; the methylpropylamide, etc., may be similarly formed.

Hydroxy halogenated benzene derivatives. Lucas P. Kyrides (to Monsanto Chemical Co.). U. S. 2,171,494, Aug. 29. Compds. are produced of high germicidal power and which have the general formula of a halogenated dihydric phenol substituted by an alkyl or acyl group, which groups have more than 4 and not more than 12 C atoms. Details are given of the production of chlorohexylresorcinol, chlorooctylresorcinol and heptylchloropyrocatechol, and general mention is made of the similar production of other Cl and Br derivs. U. S. 2,171,495 relates to monoalkyl ethers of halogenated resorcinols in which the alkyl group contains more than 3 C atoms, which have high germicidal properties. The hexyl ether of 4-chlororesorcinol is an oil, b_2 152–62°, and general mention is made of other ethers which may be similarly produced.

Bismuth carboxylates. Eli Lilly and Co., Horace A. Shonle and John H. Waldo. Brit. 506,593, June 1, 1939. Oil-sol. basic Bi salts of acids of formula $R'COCHRCO_2H$, where R is a univalent primary aliphatic radical having at least 5 C atoms and R' is an alkoxy group having not more than 4 C atoms, are obtained by causing the acid or an alkali metal salt thereof to react with a freshly prepd. Bi compd. that is sol. in an aq. soln. of glycol, e. g., the hydroxide or subnitrate. R is a noncyclic radical in which the attaching C atom is joined to only 1 other C atom of the radical, e. g., the isoamyl, 2-ethylbutyl, 2-methylamyl, 2,4-dimethylamyl, 2-ethylhexyl, decyl, dodecyl, octadecyl or 9,10-octadecenyl radical, and R' is preferably Et though it may be Me, Pr or Bu. Solns. in oil of the basic Bi salts are effective *spirocheticidal agents* and may be injected intramuscularly. Cf. *C. A.* **33**, 3077[7].

Alkyl thio-substituted benzoic acid alkamine ester salts and intermediates. John J. Donleavy (to Pitman-Moore Co.). U. S. 2,173,827, Sept. 26. Products, various of which are of relatively high effectiveness and low toxicity when used as *local anesthetics*, as when used in the form of their citrates, comprise esters (various properties and details of prepn. of which are given) such as *o*-ethylthiobenzoates: diethylaminoethyl, diethylaminopropyl, piperidinoethyl, dibutylaminoethyl; *o*-propylthiobenzoates: diethylaminoethyl, diethylaminopropyl, piperidinoethyl, dibutylaminoethyl; *o*-butylthiobenzoates: diethylaminoethyl, diethylaminopropyl, piperidinoethyl, dibutylaminoethyl; *m*-methylthiobenzoates: diethylaminoethyl, diethylaminopropyl; *m*-ethylthiobenzoates: diethylaminoethyl, diethylaminopropyl, piperidinoethyl; *m*-propylthiobenzoates: diethylaminoethyl, diethylaminopropyl, piperidinoethyl; *m*-butylthiobenzoates: diethylaminoethyl, diethylaminopropyl, piperidinoethyl; and *p*-ethylthiobenzoates: diethylaminoethyl, diethylaminopropyl.

Benzyloxyaryl aromatic sulfonates. Courtland L. Butler and Leonard H. Cretcher (to Mellon Institute of Industrial Research). U. S. 2,172,606, Sept. 12. By effecting reaction between the monobenzyl ethers of various glycols and aromatic sulfonyl chlorides, in the presence of an alk. condensing agent such as pyridine, intermediate products are obtained such as benzyloxyethyl benzenesulfonate, benzyloxyethyl *p*-toluenesulfonate, 3-benzyloxypropyl *p*-toluenesulfonate, 1-benzyloxy-2-propyl *p*-toluenesulfonate, and from these substances other products such as benzyloxyethyl phenyl ether, benzyloxyethyl (*p*-dibenzyloxyethylaminophenyl) ether and phenylmorpholine *p*-hydroxyethyl ether, benzyloxyethyl 8-quinolyl ether, hydroxyethyl 8-quinolyl ether, benzyloxyethylapocupreine, benzyloxyethylhydrocupreine, 3-benzyloxypropylapocupreine, benzyloxyisopropylapocupreine, hydroxyethylapocupreine, hydroxyethylhydrocupreine, 3-hydroxypropylapocupreine, and (1-hydroxy-2-propyl)apocupreine are obtained by reactions some details of which are given. U. S. 2,172,607–8 (Courtland L. Butler, Leonard H. Cretcher and Alice G. Renfrew, joint inventors; to same assignee) also relate to the prepn. of various of the compds. just listed, which have a highly *antipneumococcic effect*.

Organo-arsenic compounds. I. G. Farbenindustrie A.-G. Brit. 507,186, June 12, 1939. *sym*-Bis(dihydroxyalkyl)aminoarsenobenzenes are prepd. by reducing the corresponding arsonic acids. The *products possess therapeutic properties*. Among examples, 3,3'-bis[bis(dihydroxypropyl)amino]-4,4'-dihydroxyarsenobenzene is prepd. by reducing 3-[bis(dihydroxypropyl)amino]-4-hydroxybenzenearsonic acid with H_3PO_2, the arsonic acid

being used as its hydrochloride and the free base being obtained from the resulting arsenobenzene-di-HCl by neutralization with Na_2CO_3 and pptn. with EtOH.

Precipitating tannins from the air, as for hay-fever prevention. Robert R. Means and Harry E. Lederer. U. S. 2,176,592, Oct. 17. A compn. suitable for application to the nasal mucous membrane is formed of ingredients such as $Ca(OH)_2$ 0.5 grain, gelatin 1 grain and water 1 oz.

Carbonic acid derivatives of androstanolones. Karl Miescher and Hans Kaegi (to Soc. pour l'ind. chim. à Bâle). U. S. 2,173,423, Sept. 19. *Therapeutic compds.* are produced by reaction of satd. and unsatd. hydroxy ketones of the type of the androstanolones with phosgene, halogen carbonic esters, urea halides or isocyanates. Details are given of the production of the chlorocarbonic ester of Δ^4-androsten-3-on-17-ol, m. (decompn.) 139–40°; the chlorocarbonic ester of Δ^5-androsten-17-on-3-ol, m. 126–7°; the Δ^4-androsten-3-on-17-ol M_g carbonate, m. about 142°; the hydrochloride of Δ^4-androsten-3-on-17-ol β-diethylaminoethyl carbonate, m. 178–80°; Δ^4-androsten-3-on-17-ol carbamate, m. 160–1°; Δ^4-androsten-3-on-17-ol ethylcarbonate, m. 142°; and general mention is made of the possible similar production of other compds. such as Δ^4-androsten-3-on-17-ol ethyl carbonate, m. 142°; Δ^4-androsten-3-on-17-ol propyl carbonate, m. 87–8°; Δ^4-androsten-3-on-17-ol phenyl carbonate, m. 144–5°; Δ^4-androsten-3-on-17-ol benzyl carbonate, m. 156–7°; Δ^4-androsten-3-on-17-ol propylcarbamate, m. 190–1.5°, from Δ^4-androsten-3-on-17-ol chlorocarbonate and propylamine; and the Δ^5-androsten-17-on-3-ol carbamate, m. 207–8°, from Δ^5-androsten-17-on-3-ol chlorocarbonate and ammonia. In similar manner there are also obtained testosterone 17-diethylaminoethylcarbamate, Δ^5-androsten-17-on-3-ol methyl carbonate, m. 194–6°; Δ^5-androsten-17-on-3-ol phenyl carbonate, m. 170–2°; Δ^5-androsten-17-on-3-ol benzyl carbonate, m. 159–60.5°; and corresponding derivs. of the androstan-3-on-17-ol and androstan-17-on-3-ol.

Compounds of the androstane and pregnane series. Adolf Butenandt and Willy Logemann (to Schering A.-G.) U. S. 2,170,124, Aug. 22. Therapeutic or intermediate compds. are produced by treatment of unsatd. compds. of the androstane and pregnane series, which possess in a position adjacent to the C-to-C double bond a methylene group, with oxidizing agents such as CrO_3, for converting the methylene group into a carbonyl group without protection of the double bond; and reduction products of derivs. richer in O of the androstane and pregnane series are produced by a process in which reducible compds. of these series contg. at least 3 O atoms directly connected to the C atoms of the androstane or pregnane system are subjected to the action of reducing agents such as Al isopropylate (suitably in the presence of a noble metal catalyst). Details are given of the production of various compds., including: 7-oxy-Δ^5-3,17-androstenediol diacetate, m. 219–20°; 7-oxo-Δ^5-3,17-androstenediol, m. 201°; 6-oxotestosterone acetate; 6-oxotestosterone; 3,6-androstanedione-5,17-diol 17-monoacetate; androstenetrione, m. 216–17°; 3,6,17-androstanetrion-5-ol; 7-hydroxyandrostenediol diacetate, m. 241–2°; 7-oxo-androstanediol diacetate, m. 193–4°; 7-hydroxyandrostanediol diacetate; Δ^5-androstene-3,7,17-triol tribenzoate, m. 250–1°; and $\Delta^{5,8}$-androstadien-17-ol-7-one, m. 171–2°.

Therapeutic bactericidal sulfonamides of 2-aminopyridines. Carl Naegeli (to Cilag, Chemisches Industrielles Laboratorium A.-G.). U. S. 2,170,209, Aug. 22. Details are given of the production of the following compds., various of which, or their salts, are suitable for subcutaneous, intramuscular or intravenous injection: 2-aminopyridine-5-sulfonamide, m. 175–6°; 2-ethylaminopyridine-5-sulfonamide, m. 189–91°; 2-butylaminopyridine-5-sulfonamide, m. 121–2°; 2-allylaminopyridine-5-sulfonamide, m. 195–201°; 2-phenylaminopyridine-5-sulfonamide, m. 181–3°; 2-benzylaminopyridine-5-sulfonamide, m. 197–201°; 2-diethylaminopyridine-5-sulfonamide, m. 116–17°; 2-chloropyridine-5-sulfonanilide, m. 149–51°; 2-aminopyridine-5-sulfonanilide, m. 177–8.5°; 2-ethylaminopyridine-5-ethylsulfonamide, m. 139–141°; 2-benzoylaminopyridine-5-sulfonylbenzoylamide, m. 221–3°; and a mixt. of 2-(2′-amino-6′-pyridyl)-aminopyridine-5-sulfonamide and 2′,6′-bis(2-amino-5-pyridylsulfonylamino)pyridine.

Sulfonic acid amide compounds (suitable for combating streptococci infection). Robert Behnisch, Josef Klarer and Fritz Mietzsch (to Winthrop Chemical Co.). U. S. 2,169,971, Aug. 15. By treating an aromatic amino group of benzenesulfonamides which either contain a sulfonamide group in *p*-position to the amino group attached to the nucleus or several sulfonamide groups in the nucleus and which may also contain further substituents in the nucleus, with acylating agents of 5 or more C atoms, such as acid halides, esters, anhydrides or azides, products are obtained such as: 4-oleoylaminobenzenesulfonamide, m. 197°; 4-caproylaminobenzenesulfonamide, m. 201°; 4-caprylylaminobenzenesulfonamide, m. 189°; 4-caprylaminobenzenesulfonamide, m. 198°; 4-lauroylaminobenzenesulfonamide, m. 198°; 4-myristoylaminobenzenesulfonamide, m. 203°; 4-palmitoylaminobenzenesulfonamide, m. 202°; 4-stearoylaminobenzenesulfonamide, m. 201°; 4-undecylenoylaminobenzenesulfonamide, m. 199°; 4-erucoylaminobenzenesulfonamide, m. 177°; 4-behenoylaminobenzenesulfonamide, m. 171°; 4-phenylacetylaminobenzenesulfonamide, m. 201°; lauroylaminobenzene-3,5-di(sulfondimethylamide), m. 96°; 4-lauroylaminobenzenesulfonbenzylamide, m. 134°; 4-lauroylaminobenzenesulfonbutylamide, m. 113°; 4-lauroylaminobenzenesulfonic acid piperidide, m. 103°; 4-cinnamoylaminobenzenesulfonamide, m. 265°; 4-cinnamoylaminobenzenesulfondiethylamide, m. 157°; 4-oleoylamino-3,6-dimethoxybenzenesulfonamide, m. 145°; 4-oleoylamino-3,6-dimethylbenzenesulfonamide, m. 207°; 4-oleoylamino-3-methylbenzenesulfonamide, m. 138–40°; 4-oleoylamino-2-methylbenzenesulfonamide, m. 150°; 4-oleoylamino-3-methoxy-6-methylbenzenesulfonamide, m. 148°; 4-isovalerylamino-3-methoxy-6-methylbenzenesulfonamide, m. 187°; 4-isovalerylamino-benzenesulfonamide, m. 213°; and 4-isovalerylamino-benzenesulfoncyclohexylamide, m. 197°. Details are given of the production of various of these compds.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

Experiments on reducing the loss of lead in the sulfuric acid tower and chamber process. Hans Lohfert. *Chem. Fabrik* **1939**, 499–502.—The expts. consisted in coating Pb with $PbSO_4$ by pickling in acid of 9.1–65.5°Bé. before subjecting it to the action of chamber acid. It was found that the behavior of the coatings depends on their phys. properties more than on the thickness; that the weaker the acid and the longer the time of pickling the better the results, but that pickling above room temp. did not shorten the time, and that the purity of the pickle acid did not seem to be important. Considerable savings were indicated. Detailed results are tabulated. J. H. M.

Sources of natural sulfates in U. S. S. R. B. V. Yasnopol'skiĭ. *Byull. Inst. Halurgii* **1938**, No. 8, 1–26; *Khim. Referat. Zhur.* **2**, No. 4, 45(1939).—The sulfate lakes near the Aral Sea in the region of Dzhaksa-Klych lake are very important supply bases for sulfates. A preliminary estn. of the supplies of mirabilite is 3.9 million tons. When calcd. as dry substance the sulfate contains Na_2SO_4 88–96, $CaSO_4$ 4–1 and NaCl 1–1.7%. In 1938, 50,000 tons of the anhydrous sulfate were obtained. Tenardite is produced continuously, while the natural dehydration of mirabilite takes place only during the summer. Lake Chumym-Kul, which lies below sea level, is a natural reservoir in

which sea water can be evapd. naturally during the hot summer days. **New deposits of sulfates in the Aral Sea region.** S. E. Maksimov, A. A. Unkovskiĭ and M. A. Kuksova. *Ibid.* 27–31.—In the Sadir-Baĭ region to the south of the main sulfate deposits of Dzhaksy-Klych, there are 20 sulfate lakes, 3 tenardite lakes and 2 astrakanite lakes. W. R. Henn 1

The production of calcium nitrate and elementary sulfur from gypsum. S. N. Ganz. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 40–2 (1939).—$CaSO_4$ is heated with C at 900° to give CaS and SO_2. The CaS is treated under pressure with CO_2 and H_2O to give $CaCO_3$ and H_2S, which reacts with SO_2 to give S. The $CaCO_3$ is dissolved in HNO_3 and the CO_2 formed is used in treating the CaS. H. M. L. 2

The formation of gypsum incrustations in the distiller in ammonia-soda production. V. R. Terashkevich, S. S. Urazovskiĭ, R. E. Shtok and E. M. Eĭdel'man. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 12–16 (1939). SO_4 in the soln. causes pptn. of $CaSO_4$ when $Ca(OH)_2$ is added in the distiller. Above 95°, flakey $CaSO_4.0.5H_2O$ is formed; below 95°, the harder $CaSO_4$ ppts. as an incrustation. At sulfate concns. below 0.35 g. equiv. per l., no $CaSO_4$ ppts. Temps. between 85 and 105° have little effect on the amt. of pptn. The presence of $CaCl_2$ decreases the soly. of $CaSO_4$. H. M. Leicester 3

The composition of the precipitate deposited in soda-production apparatus and measures for avoiding it. II. V. E. Voronchikhin. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 17–21 (1939); cf. *C. A.* **31**, 2364[8]. The deposit in various parts of the app. consists of varying proportions of $CaCO_3$ and $MgCO_3$, mixed with NaCl and Na_2CO_3 or $NaHCO_3$. Fine crystals of $CaCO_3$ do not tend to accumulate, but may collect around dust particles to form thick incrustations. Therefore, the liquid should be covered at all times. Mg compds. cause incrustation most actively, and Mg should be removed as completely as possible. Pptd. $Mg(OH)_2$ is as bad as sol. Mg salts if it is allowed to circulate with the brine, since it redissolves and ppts. as $MgCO_3$. H. M. Leicester 4

Rationalization of the process for obtaining sodium sulfide. F. A. Romaslovskiĭ. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 51–4 (1939).—Modifications are suggested in the app. for burning Na_2SO_4 with C. H. M. L. 5

The Kerch boron problem. L. M. Zarudskiĭ and B. Ya. Rozen. *Byull. Inst. Halurgii* **1938**, No. 6, 42–53; *Khim. Referat. Zhur.* **2**, No. 4, 45 (1939).—Before the discovery of the Inder borate deposits (ascharite and hydroboracite) the Kerch deposits were the only com. source of B in U. S. S. R. The av. content of B_2O_3 is only 0.3–0.4%. The Inder deposits of borates contain 25–7% of B_2O_3. In spite of the relatively poor content of the borates in the Kerch deposits they still can be utilized under certain conditions. W. R. Henn 6

Boron in the salt lakes of the Mangyshlak Peninsula. N. B. Feĭgel'son and A. A. Kozhevnikova. *Byull. Inst. Halurgii* **1938**, No. 7, 1–7; *Khim. Referat. Zhur.* **2**, No. 4, 44 (1939).—The B content in the salt lakes of the Mangyshlak Peninsula varies from 0.202% to 0.045% (calcd. as H_3BO_3). In the Karabogaz Gulf the H_3BO_3 content is 0.25% of the total salt content, and in the Caspian Sea 0.28%; the H_3BO_3 content in sea water is only 0.005% of the total salt. The H_3BO_3 salts dissolve in pure water to a much smaller degree than $MgCl_2$ and $MgSO_4$. Therefore, it would be expected that under the conditions of the salt lakes the H_3BO_3 salts will be deposited before NaCl. This was not the case, except in the lake Krasnoe, where traces of H_3BO_3 were found in layers of NaCl. It is concluded that $MgSO_4$ may increase the soly. of the borates and that H_3BO_3 is concd. in the mother liquor during the evapn. of the solns. W. R. Henn 7

Utilization of lake brines for the production of mirabilite and magnesium compounds. V. I. Nikolaev, E. V. Gritsevich and L. S. Dynkina. *Compt. rend. acad. sci. U. R. S. S.* **24**, 338–9 (1939) (in English).—The pptn. of Na_2SO_4, $MgSO_4$ and $MgCl_2$ from the Karabogaz brines (Kalmuck Soviet Socialist Republic) is plotted in graphs on the basis of lab. expts. Cooling (in winter) to −8° of brine collected in July and August ppts. Na_2SO_4. The method of drying by the sun should be replaced by the use of Na metasilicate. After deposition of Na_2SO_4, the brines can be evapd. further to produce $MgCl_2$. A. H. Krappe 8

The probable composition of the saline water of Lake Kuchuk. O. D. Kashkarov. *Byull. Inst. Halurgii* **1938**, No. 3, 33–41; *Khim. Referat. Zhur.* **2**, No. 4, 45 (1939).—In a desire to find the probable compn. of the saline water of the Kuchuk lake at the beginning of the fall deposition of mirabilite, there were analyzed statistically the results of the 10-year investigations of the chem. compn. of the water. The results show that after 68 years the saline water will contain less than 12% Cl, which is the only factor which guarantees a fair purity of mirabilite. The ratio SO_4:Cl increases for the summer period simultaneously with an increase of the Cl content; this can be connected with the gradual soln. of the mirabilite which has been deposited during the winter. The depth and the dimensions of the lake det. the velocity of the process of soln. and at the same time limit the max. concn. of SO_4^{--} which can be reached during the summer period. W. R. Henn 9

Salts of Inder Lake. A. N. Volkov. *Byull. Inst. Halurgii* **1938**, No. 2, 20–67; *Khim. Referat. Zhur.* **2**, No. 4, 46 (1939); cf. *C. A.* **32**, 6983[7].—The main mineral component of the salt waters which feed Inder Lake is NaCl; there are smaller amts. of K salts, $MgCl_2$ and $MgSO_4$. The compn. of the water of Inder Lake is NaCl 19.6–23.9, KCl 0.10–2.1, $MgCl_2$ 1.74–4.57, $MgSO_4$ 0.35–0.49, $CaSO_4$ 0.04–0.3 and $Ca(HCO_3)_2$ 0.05–0.13%. In a crevice in the center of the lake, NaCl (varying from 88 to 99%) is the main component of the salt mass to a depth of 33 m. There are also present 0.03–0.23% of KCl, 0.002–0.04% of KBr and 0.007–0.009% of B_2O_3. The total supply of salt is estimated at 1500 million cu. m. W. R. Henn 10

Laws of solar evaporation of salt solutions from observations in the Kulundin steppe. O. D. Kashkarov. *Byull. Inst. Halurgii* **1938**, No. 6, 31–40; *Khim. Referat. Zhur.* **2** No. 4, 31 (1939).—The adaptability of the equations of Meier, Parshal and Karkentner for the evapn. of water from large reservoirs was verified by calcg. the evapn. of a no. of fresh-water American reservoirs. Most suitable for the calcn. is the Meier equation, $E = 0.707(n/2)(H-h)(1 + 0.224\ V)$, where E is the amt. of the evapd. water in kg./sq. m., n the no. of days of evapn., H the vapor pressure of water, h the abs. humidity and V the velocity of the wind in m./sec. at a height of 4.5 m. Expts. were made on the evapn. of the saline water of Lake Kuchuk from 2 reservoirs (surface 500–600 sq. m.) and from crystallizers (surface 250–300 sq. cm.). The vapor pressure of the saline water was at the exptly. detd. b. p. *in vacuo*, and the amt. of the evapd. water was calcd. from the change of the compn. of the saline water and from the detn. of the amt. of salts and ppts. of the saline water. A satisfactory accuracy (8–9%) was obtained for these reservoirs by calcn. from $E = 0.372(H-h)(1 + 0.224\ V)n$. W. R. H. 11

Annual changes in the hydrochemical conditions in the Yashalta lakes. V. I. Nikolaev and B. I. Stepanov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 334–7 (1939) (in English).—Chem. analysis of the brines of the Yashalta lakes (Kalmuck Soviet Socialist Republic) at different seasons (figures in tables) disclosed that at the beginning and end of the year the brines are dild. and unsatd. From the middle of March to the middle of May the coeff. of metamorphism becomes so high that $MgCl_2$ disappears and the ratio $MgSO_4/MgCl_2$ is replaced by the ratio $Na_2SO_4/MgSO_4$, which is explained by the inflow of spring waters. On about May 20th intense evapn. sets in (temp. 30° and more); the coeff. of metamorphism settles at about 1.4–1.5. At the end of July or in August NaCl begins to ppt. The total of salts in August 1938 amounted to 29.10%. A. H. Krappe 12

The composition of water of the Karabogaz gulf in connection with the drop of the Caspian Sea level. N. A. Shreders. *Byull. Inst. Halurgii* **1938**, No. 6, 54–68; *Khim. Referat. Zhur.* **2**, No. 4, 47 (1939).—The water level of the Caspian Sea dropped in 1937 by 103 cm., as compared with the 1929 level, which was the av. level of

the preceding 100 years. This caused a decrease of the water flowing into the Karabogaz gulf from 19.5 to 9.52 cu. km. Previously the saline water of the Karabogaz gulf became satd. with respect to Glauber's salt at 5.5 6°, when it was deposited and became of com. importance. The new concn. of salts in the water causes the pptn. not only of $Na_2SO_4.10H_2O$, but also of NaCl. New ways for preserving the purity of the Glauber's salt deposits must be found. W. R. Henn

Apparatus for keeping and transporting large amounts of liquid oxygen. S. M. Rips. *J. Chem. Ind.* (U. S. S. R.) 16, No 8, 43–4 (1939).—Equations are derived for calcg. the conditions for use of a spherical container for liquid O. H. M. Leicester

The velocity of adsorption on carbon. E. Angelescu and E. Soloviu. *Bul. Soc. Chim. Romania* **20A**, 197–223 (1938) (in French).—The adsorption of the acids (oxalic, acetic, propionic and butyric) and of mixts. of oxalic acid with these acids and with H_2SO_4 on the active carbons, *Norit* and *Pick*, was measured at definite time intervals. The observed velocities of adsorption cannot be expressed by any of the proposed simple formulas. L. E. Steiner

---

Blowing coke gases into blast furnace [blast-furnace gas for NH_3 synthesis] (Shapovalov) 9.

Aluminates. Hans Zirngibl (to I. G. Farbenind. A.-G.). U. S. 2,176,444, Oct. 17. See Fr. 839,961 (*C. A.* 33, 7969[2]).

Condensing materials such as antimony trioxide into particles of desired and substantially uniform size. Melville F. Perkins and Albert J. Phillips (to American Smelting and Refining Co.). U. S. 2,177,551, Oct. 24. App. is described, and a process for treating fluid streams carrying various sublimable materials in vapor phase, which involves introducing a fluid stream carrying such materials into the lower portion of a quenching fluid stream, such as air of substantially greater d. and at substantially lower temp. than the first-mentioned stream, so as to cause the latter to rise through the quenching stream, and maintaining the conditions of relative volumes of the streams, velocity, concn. and temp. such as to produce substantially instantaneously at the point of mixing a condensation of the materials directly into solid particles of high concn. of a predetd., closely controlled and standardized particle size and fixed crystal form.

Cadmium selenide. Neil E. Gordon and Edgar C. Pitzer (to Chemical Foundation, Inc.). U. S. 2,176,495, Oct. 17. For producing substantially pure CdSe, $CdSO_4$ is treated in an aq. medium with a substantial excess of alkali selenosulfate, the Cd selenosulfate formed is hydrolyzed to CdSe in the presence of the selenosulfate (as at a temp. of 60–100°), the ppt. is sepd. by filtration, and the filtrate is re-employed with addnl $CdSO_4$ for producing an addnl. quantity of CdSe.

Lime production from carbonate sludge. Dudley Baird (to Nichols Engineering & Research Corp.). U. S. 2,176,239, Oct. 17. See Can. 382,612 (*C. A.* 33, 7971[2]).

Ferric oxide. Urban E. Bowes. U. S. 2,176,242, Oct. 17. App. is described, and a method of obtaining Fe_2O_3 from a compn. in which it is contained, such as an ore, which involves flowing HCl through a mass of the compn. at a temp. above the temp. at which $FeCl_3$ volatilizes, to produce a gaseous mixt. of $FeCl_3$ and steam, sepg. the gaseous mixt. from the compn., lowering the temp. of the mixt. to reverse the original reaction a substantial degree and produce HCl and Fe_2O_3, and so limiting the amt. of HCl in proportion to the gaseous $FeCl_3$ formed 1 that after sepg. the gaseous $FeCl_3$ and steam from the mass a substantial degree of reversal of the original reaction is effected on the lowering of the temp. of the mixt. of $FeCl_3$ and steam.

Sodium chromate, etc. Marvin J. Udy. U. S. 2,176,685, Oct. 17. In a process involving oxidation of ferro-Cr in finely divided form at an elevated temp. below its m. p. and in the presence of CaO and Na_2CO_3, the Na_2CO_3 is employed in the amt. required to form Na chromate with 2 about half of the Cr of the ferro-Cr and the CaO is employed in an amt. in excess of that required to form Ca chromate with the remainder of the Cr of the ferro-Cr, so that an oxidized product is formed contg. about equimol. proportions of Na and Ca chromates. This product may be treated with H_2SO_4 to ppt. $CaSO_4$ and produce $Na_2Cr_2O_7$.

Removing fluorine compounds from acid bone liquors. Milton H. Merchant (to American Agricultural Chemical Co.). U. S. 2,176,464, Oct. 17. In a process of purifying, an acid bone liquor, such as that obtained by treating 3 bones with a dil. acid, such as HCl, which gives only sol. Ca salts, which liquor contains Ca, the PO_4 radical and a dissolved F compd. and in which the Ca·PO_4 ratio is not less than in tri-Ca phosphate, also contg. a sol. Ca salt other than acid Ca phosphate, and in which Ca and PO_4 are maintained in soln. by excess acid, the liquor, contg. not more than about 11% total solids, is treated with an 4 alk. Na compd., such as NaOH, and a sol. Al compd., such as $AlCl_3$, proportioned to give the liquor a pH of about 4.0–4.3 and to ppt. substantially all the dissolved F, with agitation and removal of the F-contg. ppt. to leave a liquor substantially free from sol. F compds.

Sulfur from sulfur dioxide. Gant Gaither. U. S. 2,177,707, Oct. 31. An arrangement of app. is described, and a cyclic process for prepg. S from SO_2 which involves 5 the steps of absorbing SO_2 in an alkali carbonate soln., whereby CO_2 gas and an acid alkali sulfite soln. are formed, neutralizing the soln. with alkali carbonate to form CO_2 gas and a neutral soln. of alkali sulfite, evapg. this neutral soln. and mixing it with C and subjecting the mixt. to heat to reduce the alkali sulfite to sulfide, dissolving the sulfide and recycling the sulfide soln. to react with CO_2 evolved in the process, thus forming H_2S and alkali carbonate soln., recycling the carbonate soln. thus 6 formed to the steps of absorbing SO_2 and neutralizing acid alkali sulfite soln., and treating the H_2S with SO_2 to produce elemental S and water. Cf. *C. A.* 33, 7972[4].

Use of carbon for adsorption of solvents such as ethyl acetate. Gilbert W. Brant (to E. I. du Pont de Nemours & Co.). U. S. 2,177,473, Oct. 24. A process is employed which involves submerging carbon of vegetable origin, adapted for adsorption of solvents, in water contg. sufficient HOAc to neutralize the alky. of the C, allowing the mixt. 7 to stand until the desired neutralization has taken place, removing the wash liquid and the materials dissolved therein, washing the C with about 50 times its wt. of tap water acidified in the pH range 5–6 with HOAc over a period of about 6 hrs., and thereafter passing a solvent-laden atm. over the C to recover the solvent.

Adsorbent material suitable for drying gases or treating vegetable oils, etc. Pearl H. Brewer and Henry R. Kraybill (to Purdue Research Foundation). U. S. 2,176,851, Oct. 17. A process of making an acid-reacting adsorbent agent involves passing CO_2 into an aq. soln. of Na 8 silicate sufficiently concd. to produce a gel contg. a Na carbonate, treating the gel so formed with a slight excess of acid, such as HCl, which reacts with the carbonate to liberate CO_2 and cause the gel to expand into a solid foam, washing the solid foam with water, and drying it.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Glasses, organic and inorganic. Harry Moore. *Chemistry & Industry* **1939**, 1027–37.—A review. E. H.

Role of physics in the glass industry. I. I. Kitaigorodskii. *Uspekhi Fiz. Nauk* **21**, 338–41 (1939).—K. discusses the various types of modern glasses produced in the U. S. S. R. Cf. Sullivan, *J. Applied Phys.* 8, 122 (1937). F. H. Rathmann

A new MgF_2-SiO_2 glass. Choong Shin-Piaw. *Compt.*

rend. 209, 884–5(1939).— Though usually a fused mixt. of MgF_2 and SiO_2 forms a white opaque enamel, under "favorable circumstances" (not further specified) a transparent solid is obtained. In that case there is a marked increase in density (2.73–2.82, usually 2.81, as against 2.47 and 2.20 the d. of MgF_2 and SiO_2, resp.), and the glass has no definite m. p., but gradually softens at about 1460°, or some 60° and 150° below the m. ps. of its constituents. The limit of transparency may extend to λ2620, but is less as d. decreases. C. A. Silberrad

A rapid method of analysis of aluminum-magnesium glass. O. V. Krasnovskiĭ. *Shornik "Sovremennye Metody Kontr. Proizvodstva v Stekol'noĭ Prom."* **1938**, 9 13.— In one sample of glass SiO_2 and R_2O_3 are detd. In a second sample Mg and Na are detd. The glass is decompd. with a mixt. of H_2SO_4 and HF. The excess H_2SO_4 is removed and the dry residue heated to transform $Fe_2(SO_4)_3$ and $Al_2(SO_4)_3$ into their oxides. The residue is treated with water, and Fe and Al are pptd. from soln. with NH_4OH in the presence of CH_3COONH_4. From the same soln. Ca is pptd. with an $(NH_4)_2CO_3$ soln., the soln. filtered, the filtrate is evapd. and the residue heated at 550°. The calcined residue, contg. $MgSO_4$ and Na_2SO_4, is dissolved in water, Mg is pptd. with an alc. soln. of $(NH_4)_2CO_3$, the filtrate evapd., and Na detd. as Na_2SO_4. In a third sample Ca is detd. The glass is decompd. with a mixt. of HF with $H_2C_2O_4$, the fluorides are converted to oxalates by heating them with $H_2C_2O_4$, the sol. oxalates are extd. from the dry residue with water and dil. CH_3COOH. The CaC_2O_4 residue is converted to oxide and Ca is detd. as $CaSO_4$. **A rapid semimicrochemical method of the determination of silica acid and of the sesquioxides in glass** O. V. Krasnovskiĭ. *Ibid.* **1938**, 13–16.—SiO_2 can be sepd. quantitatively from the glass melt with NaOH by treating the melt once with concd. HNO_3. R_2O_3 is detd. in the filtrate from SiO_2 by the usual method. The air bath and the water bath used for the semimicrochem. method are illustrated. Through *Khim. Referat. Zhur.* 2, No. 2, 81–2(1939). W. R. Henn

Accelerated method of analysis of lime-soda-magnesia glass. E. V. Knipovich and B. F. Ivanushkin. *Stekolnaya Prom.* **14**, No. 6, 32–3(1939).—Detn. of silica: 0.7 to 0.8 g. of powd. glass is melted with 5 g. soda in a Pt crucible. The melt is cooled and transferred to a porcelain cup. It is dissolved in a HCl soln. and heated to dryness. The silica sediment is treated with HCl soln., some distd. water is added and stirred, then a gelatin soln. is added and given a 2- or 3-min. rest. It is then filtered and washed with hot water. The filtrate is carefully heated to redness. It is weighed and the percentage content of SiO_2 detd. Detn. of alkalies: To 0.5 g. powd. glass 1.0 to 1.5 g. of strong H_2SO_4 and 5 ml. HF are added; it is heated; the glass dissolves, the surplus HF evaps. first then the H_2SO_4. The dry sediment is calcined and cooled. Some hot water is added. The soln. is boiled and a soln. of hydrate of Ba oxide is added. The soln. is boiled, filtered and washed with hot water. An ammonia soln. is added. Then it is filtered. The sediment is washed and evapd. to dryness; then heated to eliminate NH_4 salts. Two or 3 drops of methyl orange are added and then titrated. Alkalies can be obtained by weighing as chlorides or sulfates. The oxides of Al, Fe, Ca and Mg are detd. in the usual way with the usual reagents. M. V. Condoide

Reply to the remarks of W. Biltz and Fr. Weibke (on my work) on the molar refraction of glasses. Ernst Kordes. *Z. anorg. allgem. Chem.* **241**, 418–20(1939); cf. *C. A.* **33**, 5139[7].—Recently taken refraction curves of simple binary glass systems (with one exception) are definitely bent and therefore do not agree with the simple summation formula of B. and W. (cf. *C. A.* **33**, 5140[3]). Their contention that K. required 4 equations for the calcn. of the molar refraction of binary glass series is based on a misunderstanding. **Reply.** Wilhelm Biltz and Friedrich Weibke. *Ibid* 421–3.—The 4 equations used by K. in his calcns. are restated; they may be contracted if desired. The contribution of K. makes use of the authors' principle and meaning and is supplementary to them. M. McM.

Factors influencing the formation of bubbles and seeds in aluminomagnesia glass melted in a sulfate soda batch. G. Yu. Zhukovskiĭ, V. V. Pollyak and M. P. Orlova. *Stekolnaya Prom.* **14**, No. 6, 26–30(1939); cf. *C. A.* **33**, 1894[7].—The results of expts. show that (1) The addn. of sulfate to the batch of an aluminomagnesia glass (corresponding to 0.5% Na_2O in the glass) improves purification. (2) The addn. of sulfate and coal at first affects purification but later improves it. (3) The increase of the concn. of SO_3 in the furnace atm. hampers purification. (4) Severe cooling lowers the no. of bubbles. (5) Repeated heating of sulfate glass after cooling produces "secondary" bubbles whose quantity is proportional to the sulfate content in the glass batch. (6) The increase of the concn. of SO_3 in the furnace atm. increases the amt. of the sulfate dissolved in the glass. M. V. Condoide

Effect of alumina on the quality of bottles worked on semiautomatic machines. V. Sh. V. E. Leonov. *Stekolnaya Prom.* **14**, No. 5, 13–14(1939).—Chem. compn. of the glass has a great effect on its working in semiautomatic machines, producing various defects in the bottles. The reduction of the alumina content of the glass from 5% to 3% eliminated the majority of defects. M. V. C.

Chemical heterogeneity of lead glasses. M. M. Skornyakov. *Optiko-Mekhan. Prom.* **9**, No. 6-7, 11–13 (1939).—Expts. showed that no liquation takes place in lead glasses. The chem. heterogeneity of glasses is accounted for by the evapn. from the surface of the glass of individual components, and the differentiation in sp. gr. of raw materials forming glass during their melting. Chem. heterogeneity of glass can be prevented by energetic stirring with a specially shaped device which prevents air bubbles from mixing with the melt. M. V. Condoide

Colloidal graphite, excellent coating for molds. Ernst Grüter. *Glashütte* **69**, 713–14(1939). The disadvantages of coatings such as oil, soap or beeswax, which have been used heretofore for lubricating molds in the production of cast glass are discussed. The use of colloidal graphite as a protection against corrosion, and methods of applying aq. colloidal graphite suspensions are explained. Its advantages are summarized as follows: Molds and machines remain cleaner; the thinness of the coating keeps the shape of the glass more accurately and improves luster; wear on molds from cleaning is minimized; the refractoriness of colloidal graphite coatings protects the metal surface of the molds and prolongs their life. M. V. C.

Classification of sand used for grinding plate glass. P. Torlin. *Stekolnaya Prom.* **14**, No. 6, 16–21(1939).— Tables give the granulometric compn. of sands used for grinding plate glass. M. V. Condoide

Window glass with a lowered alkali content. I. I. Kitaigorodskiĭ, V. I. Bokunyaeva and T. N. Keshishyan. *Stekolnaya Prom.* **14**, No. 5, 29–34(1939).—From expts on 1000 different glasses it is concluded that glasses contg. 14% Na_2O melted well when they contained RO equal to 9, 10, 11, 12, 13 and 14% Glasses contg. 16, 18, 20% RO melted well only when the ratio of CaO to MgO was 4 :1. Glasses contg. 13% Na_2O melted badly when RO was 13 or 14% and Al_2O_3 was 5%; other glasses melted well. Glasses contg. 12% Na_2O had a strong tendency to crystallize when RO was 12–18%. Glasses having RO over 18% melted satisfactorily. Glasses contg. 10% Na_2O melted satisfactorily only when RO was 16%. The best results in regard to crystn. were obtained with glasses contg. 1.5% Al_2O_3, and with RO 12, 13, 14, 16%; in glasses with RO 12 and 13%, the best were those with a ratio CaO:MgO of 4 :1; while with RO 14 and 16%, the best results were obtained with a ratio of CaO to MgO 3:1. Lower SiO_2 content gives lower viscosity at 1200° and 1100°; at 1000° and 900° glasses contg. less SiO_2 were more viscous. A table gives the recommended compn. of window glasses manufactured by the Fourcault method. M. V. C.

Milky flash glass on an apatite base. L. M. Blyumen *Stekolnaya Prom.* **15**, No. 6, 21(1939).—Attempts to use Murman apatite contg. about 40% P_2O_5 and only 1% Fe_2O_3 for opacification are discussed. The chem. compns. of glasses produced are given in a table. M. V. C.

Effect of some factors on the silvering of glass. V. M. Vinokurov and B. N. Moskvin. *Optiko-Mekhan. Prom.*

9, No. 6–7, 17–19(1939); cf. *C. A.* **33**, 8371.—(1) Expts. showed a marked difference in the behavior of reducers obtained through inversion of sugar with HNO_3, H_2SO_4 and AcOH. The concn. of the acid is of great importance for the inversion of sugar with HNO_3. With a greater concn. of acid in sugar solns., compds. are formed which accelerate the process of sugar reduction; this leads to the formation of such layers and to a lowered coeff. of utilization of the silvering soln. When sugar is inverted with H_2SO_4 or AcOH, the concn. of the latter and that of the sugar in the soln. do not affect the reducing properties, and the reducers obtained are identical with regard to their properties. The reason for the specific effect of HNO_3 is based on its oxidizing properties. Therefore, the inversion of sugar with HNO_3 is undesirable. (2) The presence of some compds. and ions in the silvering solns. and their effect on the silvering process were studied. Hydrate of Ca oxide has a retarding effect on the reducing process in the soln. and thickens the silver layer; however, this does not lower the coeff. of refraction of the silvered surface which is probably due to the structure of the layer. Na silicate also lengthens (to a definite concn. of the silicate) the silvering process and promotes a more complete deposition of silver as a metallic silver layer. However, this increase in the thickness of the layer lowers the coeff. of refraction of the silver layer which is apparently due to the formation of a coarser cryst. deposit. Because of this, Na and K silicates should be considered harmful and should not be added. The introduction of small amts. of Ca oxide into silvering solns. may be recommended. (3) The presence of ions of Al^{+++} and Ba^{++} in the silvering soln. has no effect on the silvering process. The increase in the concn. of nitrate ions lengthens the silvering process. The presence of sulfate ions has no effect. (4) The presence of up to 25% potash in the KOH soln. has no marked effect on silvering. If a greater quantity of it is present, reduction is retarded. M. V. Condoide

Classification of ceramic facing materials. I. A. Kovelman. *Keramika* **1939**, No. 6, 56–67.—A new classification based on the nature of the body and of the decoration is suggested. E. E. Stefanowsky

Causes and elimination of efflorescences on ceramic ware. P. N. Grigor'ev. *Keramika* **1939**, No. 4, 1–6.—The following corrective measures are suggested: weathering of the clay; sedumentation with very pure weakly mineralized water; substitution of weakly mineralized water for hard water, substitution of fuel lower in S; increasing the time of drying; drying with pure air, especially with hot air from Hoffmann kiln chambers; firing at higher temps. and for longer times, beginning if possible with reducing and ending with oxidizing conditions; addn. of org. materials; chem. addns., especially $BaCO_3$; washing the ware with water (art ware only). E. E. Stefanowsky

Krivoi Rog Pre-Cambrian metamorphous quartzites and vein quartzes as a raw material for silica brick. M. I. Ozhegova, S. V. Potapenko and I. S. Soloninko. *Ogneupory* **7**, 415–26(1939). E. E. Stefanowsky

Effect of steam on silica brick for coke ovens. S. L. Herman. *Ukrain. Nauch.-Issledovatel. Inst. Ogneuporov i Kislotouporov* No. **45**, 120–2(1939).—Expts. showed that steam had little or no effect at 700–1150°. M. V. C.

Occurrence of wax-like substances in peaty fire clay. V. L. Bosazza. *Nature* **144**, 835–6(1939).—Waxy substances have been extd. with Ac_2O, EtOH and C_5H_5N in 0.03 to 0.72% yield from fire clays. The substance oxidizes readily and m. about 90–100°. Attempts to ext. the pigmenting material from the clay have failed. Rachel Brown

Plasticity. I. F. Ponomarev. *Keramika* **1939**, No. 7, 1–7.—A new theory of plasticity is suggested based on the following: The ceramic mass should be considered as a heterogeneous system. Under the influence of an applied stress the plastic mass flows. The plasticity of a heterogeneous system is characterized by the mass in g. flowing in a unit of time over 1 sq. cm. of cross section of the stream. The plasticity of a heterogeneous system is affected by applied stress, temp., compn. and properties of the solid and liquid phases, and the gas phase. E. E. Stefanowsky

Experience in the production of hollow sand-lime brick. A. S. Razorenov and V. F. Abashkina. *Keramika* **1939**, No. 6, 40–4.—An ordinary sand-lime batch with 6–8% active lime can be used. Lime must be finely ground (1–2% retained on a screen, 144 meshes per sq. cm.). The moisture content of the batch must be 4–5.5%. The batch fed to a special mixer must be moistened beforehand. E. E. Stefanowsky

Rational construction of mouthpieces for molding siphon brick and tubes. I. Sh. Shvartsman. *Ogneupory* **7**, 435–7 (1939). E. E. Stefanowsky

A rapid method of determination of working properties of casting slurry. E. A. Ulatov. *Keramika* **1939**, No. 7, 41–3.—An areometer is introduced for 3 min. into a cylinder contg. the slurry, whose sp. gr. has previously been detd. by pycnometer. The difference characterizes the inner friction of the slurry ($Q = \gamma - \gamma_1$). The addn. of electrolytes decreases the friction and improves the property of giving off water, which is best when Q approximates zero. E. E. Stefanowsky

Improving saggers. P. F. Romodan. *Keramika* **1939**, No. 8, 20–7.—Durability can be improved by adding talcum or gypsum. The latter decreases shrinkage, but increases water absorption. E. E. Stefanowsky

Some defects of underglaze colors and majolica glazes for whiteware. A. Z. Barabanova and O. V. Tyzhnova. *Keramika* **1939**, No. 7, 33–6. E. E. Stefanowsky

Causes of shrinkage of decalcomania after burning and ways to correct it. P. F. Romodan. *Keramika* **1939**, No. 7, 31–3. E. E. Stefanowsky

An instant-hardening refractory cement for patching coke ovens during operation. I. L. Movshevich. *Vestnik Inzhenerov i Tekh.* **1939**, No. 1, 53; *Chem. Zentr.* **1939, II**, 2140.—The setting requirements in a hot oven, of a satisfactory cement composed of 75% "marshalite," 20% quartzite (grain size under 0.7 mm.), and 5% clay with 1–1.5% graphite and 1.25% Na_2O (in the form of water glass) are discussed. This mixt. has a porosity of 25%, a vol. shrinkage of 3.9% and a refractoriness of 1630° (beginning of deformation at 1130° under a load of 2 kg. per sq. cm.). M. V. Condoide

Refractory cement containing barium aluminate. R. Matveev. *Novosti Tekhniki* **1939**, No. 23/24, 33–4.—Three methods are suggested for prepg. refractory cements contg. $BaAl_2O_4$: (1) Bauxite, or other material contg. Al_2O_3, is fired with a mixt. of Ba salts which decomp. upon being heated or with a mixt. of Ba salts and coal. (2) Soln. of $NaAlO_2$ and Ba salt, such as BaS, is treated with CO_2; the ppt. is washed, dehydrated, fired, and ground. (3) Bauxite is fired with barite, $BaAl_2O_4$ is extd. or the mixt. is treated in an autoclave with BaS. The $BaAl_2O_4$ is treated with CO_2, dehydrated, fired and ground. The Ba cement is mixed with 20–30% of water for use. B. Z. Kamich

Sintering process of highly refractory materials. I. G. V. Kukolev and E. I. Dudavskiĭ. *Ukrain. Nauch.-Issledovatel. Inst. Ogneuporov i Kislotouprov* No. **45**, 1–37 (1939).—(1) A method of sintering highly refractory materials (contg. silicates of Ca and Mg) at lower temps., for a shorter time, and with a smaller flux content (3.5–4% R_2O_3) in the mixes, was developed. It was called "method of active components." The method was used in 3 ways: (*a*) introduction into the mix of a dispersing material consisting chiefly of γ-$2CaO.SiO_2$; (*b*) introduction of natural silicates of Mg; (*c*) introduction of double silicates of Ca and Mg. Five types of highly refractory materials were produced: (*a*) calcareous refractory (consisting chiefly of $3CaO.SiO_2$) based on CaO and sand as raw materials and dispersing product γ-$2CaO.SiO_2$; (*b*) lime-dolomite refractory (consisting chiefly of $3CaO.SiO_2$ and MgO) based on CaO, sand and dolomite and the same dispersing product; (*c*) a refractory composed chiefly of $3CaO.SiO_2$ and MgO produced from a raw material called "zmeevik" (a silicate of Mg) and dolomite; (*d*) a refractory composed chiefly of $2CaO.SiO_2$ and MgO based on dolomite and sand

and synthetic diopside as an active component, contg. Fe in solid soln.; (*e*) a refractory composed of $3CaO.SiO_2$ and MgO on the base of dolomites and sand and the same active component. The refractories obtained possess a high d. and high indexes of incipient and final softening. Especially high indexes were shown by the "zmeevik"-dolomite refractories (incipient softening under load at 1620°, 4% shrinkage at 1700° and 14% shrinkage at 1750°). M. V. Condoide

Corrosion and destruction of refractory materials in Martin furnaces. A. M. Ruban. *Sovet. Met.* **10**, No. 1, 38-44(1938); *Chem. Zentr.* **1939, II**, 1737-8.—During the first 20 melts in Martin furnaces a crystn. and further tridymite formation occurs; this contributes to the phys. and chem. stability of the lining. The destruction of the blocks by the formation of porous spots is divided into 2 stages: (1) the impregnation of the gray zone by particles of coal dust and (2) a washing out of the tridymite by fluxes. These occur simultaneously and are intensified by high temp. The assumption that a temp. of 1470° exists in the boundary between the gray and black zones was not confirmed by R. Blocks with a gray zone measuring 160-180 mm. are employed at the Kirov Works and with the smallest temp. gradation of only 3° for 1 mm. block length, a temp. of 1950° must prevail on the side of the crown next to the fire, which is not likely. The mech. destruction of Dinas and magnesite blocks can be greatly reduced by the use of suitable heat insulators. Moreover, heat insulation permits a more complete crystn. of tridymite and also a widening of the black and brown zones. The corrosion and zone structure are similar in Dinas and magnesite blocks. The structure and extent of the diffusion of the fluxes (e. g., CaO and SiO_2) are explained not only by the temp. conditions which exist in the different zones, but also by the chem. behavior of the refractory toward one or more of the diffusing oxides. While the strongly basic CaO reaches the greatest concn. in the 3rd zone of refractory Dinas material, the acid flux (SiO_2) diffuses most deeply into magnesite blocks and also reaches its greatest concn. in the 3rd zone. It is assumed that physicochem. processes which also include reactions in a solid state take place during the formation of the zones in magnesite and Dinas materials. M. V. Condoide

Slag movements in refractory bricks. Th. Schauer. *Sprechsaal* **72**, 553-4(1939).—Expts. are described to define the movement of slag into magnesite bricks and especially the Fe pickup by the refractory. A blast-furnace slag high in SiO_2 and CaO ("half acid") was allowed to react for 1 hr. at 1450° with electro-magnesite. Three zones resulted with the $CaO.SiO_2$ penetrating rather deep and causing a middle zone between the original material and the Fe-rich surface. Magnesite and fire brick in contact resulted in corrosion of the fire brick with $2MgO \cdot 2Al_2O_3.5SiO_2$ penetrating deep into the brick and an Fe-rich surface forming next to the hole caused by the corrosion. Cases are mentioned where the decrease of porosity due to solidifying slag made the brick more resistant against continued attack by slag. J. M. Noy

Spinel refractories. A. S. Berezhnoĭ and E. Z. Slonimskaya. *Ukrain. Nauch. Issledovatel. Inst. Ogneuporov i Kislotouporov* No. **45**, 78-119(1939).—Fused spinel made under lab. conditions from Al_2O_3 and $Mg(OH)_2$ has valuable properties, such as high temp. of deformation (above 1800°) under load (2kg./sq. cm.). The production process has been developed. Deformation under load begins at 1600-1650°; destruction occurs at 1660° or over. Refractoriness is over 1920. Thermal stability (air quenching) is about 30-40. The resistance to slag is not as high as mentioned in the literature. It is affected, although little, by SiO_2, CaO, Martin slag and some other materials at 1600°. The introduction of some admixts., especially of chromite, accelerates the formation of spinel. Spinel refractories can be used in contact with magnesite and even highly aluminous and chromite refractories, but contact with olivine, and especially with grog and SiO_2 refractories should be voided. Tests of spinel refractories in the crown and arch of elec. steel melting furnace XT3 showed resistance far superior to that of SiO_2 refractories. It was found possible to replace Al_2O_3 by bauxites for spinel refractories where a [illegible] ruation temp. of 1500-1550° and a refractoriness of 1825° is satisfactory. M. V. Condoide

Manufacture of chromite refractories. A. S. Berezhnoĭ and K. N. Repenko. *Ukrain. Nauch.-Issledovatel. Inst. Ogneuporov i Kislotouporov* No. **45**, 38-57(1939).—A review. Tables and diagrams are given. M. V. C.

Selection of refractory materials for the bottom of furnaces. A. I. Kramarenko and L. A. Tseitlin. *Ukrain. Nauch.-Issledovatel. Inst. Ogneuporov i Kislotouporov* No. **45**, 73-7(1939).—Russian metallurgical plants use SiO_2 semiacid grog, magnesite, talc and chromite refractories as the linings of furnace bottoms; they are unsatisfactory. In attempts to develop suitable refractories it was found that: (1) Chromite mix is not affected by slag and does not soften, but it does not sinter and slag penetrates the porous structure and soon destroys it. (2) Chrome magnesite mix does not soften and is not affected by slag. Its surface sinters and is resistant to shock and wear. There is little reaction between chrome-magnesite and slag M. V. Condoide

Glass-tank refractories. W. J. Rees. *Brit. Clayworker* **48**, 291-2(1939). E. C. Petrie

Pouring pit refractories. Everett C. Hite and Gilbert Soler. *Brick & Clay Record* **95**, No. 5, 54-6; No. 6, 52-4(1939). E. C. Petrie

Tests on the viscosity of slips. Pierre Brémond. *Rec. commun. congr. tech. ind. céram.* Apr., **1938**, 155-65; *Chem. Zentr.* **1939, II**, 1739.—Tests were made on the viscosity of suspensions of pure clay, 50% clay and 50% finely powd. quartz, 33% clay and 67% quartz, and pure quartz; and on its dependence upon the quantity of dry substance, particle form, pH of the liquid and temp. The results are given in graphs and tables. M. V. C.

Modern ground enamels. L. Vielhaber. *Emailwaren-Ind.* **16**, 241-2(1939).—Batch compns. for ground enamels with min. borax content are given M. V. Condoide

Mat enamels. L. Vielhaber. *Emailwaren-Ind.* **16**, 228-9(1939).—When mat enamel is desired, as for blackboards in schools, the mat effect can be obtained on glossy enamels by sand blasting, salt treatment, etching with HF, stamping with a printing color or burning. A batch for a mat enamel in which the borax content is almost entirely replaced by ZnO and Na_2O and which retains practically the same expansion and fusibility is: feldspar 29, quartz 16, cryolite 10, soda 12.5, saltpeter 4, fluorspar 4, Sb_2O_5 5, ZnO 9.5, with 5% clay added to the mill. M. V. C.

Manufacture of acid-stable enamels. L. Vielhaber. *Emailwaren-Ind.* **16**, 221-2(1939).—Acidproof enamel batches are given (Andrews) which were defective when fired on metal. Conclusion: Tests for acid stability are important only for enamels whose value for enameling work has already been established. M. V. Condoide

Determining the physical properties of enamels. L. Vielhaber. *Emailwaren-Ind.* **16**, 205-6(1939).—When enamel is fused to metal it assumes an entirely different structure. The enamel layer is permeated with small bubbles which change many properties, such as the thermal cond., which varies with the size and no. of bubbles, which in turn are dependent chiefly upon the grinding fineness of the enamel. The expansion due to heat of iron which has been enameled is less than that of iron alone before enameling, but greater than that of the enamel alone; this is also explained by the presence of the small bubbles. It is therefore obvious that tests on heat expansion, elasticity, resistance to pressure, etc., of enamels must be made on enameled ware instead of on the enamel alone. Other factors, such as the duration of firing, may influence the formation of bubbles. The control of the size of bubbles is possible by microscopic study. M. V. Condoide

State of the enamel melt. R. Aldinger. *Glashütte* **69**, 749-51(1939).—The type and method of fusing are very important for subsequent treatment. It is here that the expression "state of the melt" of enamels arose. Fusing various types of enamel is discussed. M. V. Condoide

Spraying equipment. L. Vielhaber. *Emaillieren-Ind.* 16, 207–8(1939). M. V. Condoide

Cast iron, pottery, and sanitary wet enamels past and present. H. Kerstan. *Glashütte* 69, 714–15(1939).—The compn. and chem. analysis of wet ground enamels for pottery and sanitary ware are given. In batches used in the past the low B_2O_3, high Al_2O_3 and relatively high expansion coeff. are notable. Cryolite was first used in 1890. Manuf. of enamel in past times is described. M. V. Condoide

Enameling defects and their origin. R. Aldinger. *Glashütte* 69, 589–92(1939); cf. *C. A.* 33, 6013⁴.—Two types of defects are discussed, the bursting off of enamel at edges and dark points in enamel. M. V. Condoide

Fine cracks in enamel. R. Aldinger. *Glashütte* 69, 738–9(1939). M. V. Condoide

App. for luminescence analysis and its use for examn. of silicates (Shvetsov, *et al.*) 1.

Searle, A. B.: Refractories. London: Crosby Lockwood. 102 pp. 3s. 6d. Reviewed in *Blast Furnace Steel Plant* 28, 104 (1940).

Glass vessels such as baking dishes. Wm. W. Shaver and Harold K. Martin (to Corning Glass Works). U. S. 2,177,336, Oct. 24. Vessels are formed with surface layers under compression and an inner tension zone the max. degree of tension of which per sq. mm. does not exceed 2.6 kg. Such vessels are not subject to "explosive fracture." 4

Apparatus for feeding articles such as bottles or other glassware to lehrs for annealing. Norman R. Beck (to Carr-Lowrey Glass Co.). U. S. 2,176,241, Oct. 17. Various structural, mech. and operative details.

Bending glass sheets. Robert A. Miller (to Pittsburgh Plate Glass Co.). U. S. 2,176,999, Oct. 24. App. is described, and a method of bending a glass sheet which involves supporting it at opposite extremities in a horizontal position with the intermediate portion unsupported, heating the entire sheet to a high temp., but below the softening temp. of the glass, applying radiant heat to each face the intermediate sheet portion along a narrow band only extending across the sheet to heat such band to a bending temp. so that the sheet bends by gravity, and limiting the bending movement to produce a predetd. contour. 6

Coated glass sheets. Arthur D. Nash (to Pittsburgh Plate Glass Co.). U. S. 2,177,000, Oct. 24. App. is described, and a method of making a glass sheet which involves withdrawing a sheet continuously from a molten bath of clear glass in such manner that the surface glass in the bath moves forwardly relative to the body of the bath as the sheet is formed, and applying continuously to such surface a layer of unfused vitreous glazing material which is fused on the surface of the bath and remains thereon and forms the surface layer of one side of the sheet. 7

Apparatus for producing ground and polished glass strip. Frederic B. Waldron and Frank Slocombe (to Pilkington Bros. Ltd.). U. S. 2,176,480-1, Oct. 17. Various structural, mech. and operative details.

Tempered glass articles such as sheet glass for windshields. Bernard Long (to American Securit Co.). U. S. 2,177,324, Oct. 24. In order to divide a tempered glass article such as a sheet into several pieces, there is produced along the periphery of each piece to be obtained a band in which the glass is untempered and the fragmentation of the glass is effected in the zones of tempered glass outside these pieces.

Composite interlayer for cementing together plates of laminated safety glass. Herman R. Marini (to Pittsburgh Plate Glass Co.). U. S. 2,176,997, Oct. 24. A layer such as a plasticized polyvinyl acetal resin of tacky character is used between layers of unplasticized nontacky synthetic resin of normally nonadherent character but which can be bonded with plates of glass by heat and pressure. 3

Improving the properties of sheeting such as that of a cellulose acetate composition for use in laminating glass. John S. Kimble and John S. McLellan (to Eastman Kodak Co.). U. S. 2,177,659, Oct. 31. App. is described, and a continuous method of improving the phys. characteristics of a thermoplastic sheeting of cellulose org. deriv. which comprises heating the sheet in a heating chamber while supporting the sheet without substantial tension being exerted thereon, reducing the thickness of the sheet in a series of calenders, heating the sheet between the calenders to facilitate calendering, and cooling the sheet while it is under substantially no tension.

Laminated glass. Carleton Ellis (to Ellis-Foster Co.). U. S. 2,176,837, Oct. 17. At least 2 panes of light-transmitting glass are bonded together by a composite light-transmitting mixt. such as glass fiber and a resinous compn. such as a synthetic resin having substantially the same n as the glass. Cellulose esters also may be used with glass fiber. 5

Hermetic, electrically conductive seals suitable for use with tungsten and quartz. Cornelis Bol, Gottfried B. Jonas and Hendricus J. Lemmens (to General Elec. Co.) U. S. 2,177,685, Oct. 31. For sealing, a glass is used substantially free from alkali and having a coeff. of expansion less than that of W, such as one contg. SiO_2 88.3, B_2O_3 8.4, Al_2O_3 2.9 and CaO 0.4%.

Checkerwork for regenerators such as those of open hearth or glass-tank furnaces. Henry Tanner (to Chicago Retort and Fire Brick Co.). U. S. 2,176,157, Oct. 17. Various structural details.

Abrasive sheets and disks, etc. Lawrence V. Redman (to Behr-Manning Corp.). U. S. 2,176,942, Oct. [illegible]. A flexible base such as paper or cloth carries abrasive grains held by a binder including a phenol-oil resin reaction product such as may be formed from tung oil, phenol and $(CH_2)_6N_4$, etc.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Development of portland cement. E. M. Schroder. *Soc. Chem. Ind. Victoria, Proc.* 39, 202–16(1939). E. H.

Calcium diborate hexahydrate from a mortar of portland cement and colemanite. M. A. Peacock and V. A. Vigfusson. *Univ. Toronto Studies, Geol. Ser.* No. 42, 113–21 (1939).—Portland cement briquets made from 1 part cement and 4 parts colemanite ($Ca_2B_6O_{11}.5H_2O$) were prepd. in the usual manner. After 14 months large clear and transparent crystals were attached to the briquet surfaces. The compn. of these crystals is $CaB_2O_4.6H_2O$ and their formation may be expressed in the reaction: colemanite + $Ca(OH)_2$ + H_2O = $CaB_2O_4.6H_2O$. Two g. of this latter compd. dissolves in 1 l. water at 10° and gives an alk. soln. It is stable toward atm. CO_2 but rapidly loses its hydration at 80°. The crystals are colorless, sp. gr. 1.881, are biaxial, neg., with low refringence and moderate birefringence. X-ray measurements gave the lattice parameters a_0 = 7.97, b_0 = 6.614, c_0 = 7.977 A and β = 104°25′. The unit cell consists of $Ca_2B_4O_8.12H_2O$. H. E. Messmore

Increasing the activity of Roman cement. G. Aristov. *Keramika* 1939, No. 6, 54–6.—The activity of Roman cement can be increased by adding about 2% by wt. of slaked lime. The mechanical strength of activated cement is higher. E. E. Stefanowsky

Hydrotechnical cements. V. N. Yung. *Tsement* 6, No. 6, 20–33(1939).—As a most appropriate cement for hydrotechnical construction is suggested a three-component sand-pozzuolanic cement consisting of 50% of clinker

and 50% of addns. Its silica content amounts to 55–60%. E. E. Stefanowsky

Corrosion of cements under the action of gases of waste waters. V. P. Makhaev and P. S. Kaverin. *Vodosnabzhenie i Sanit. Tekh.* **1938**, No. 11, 81–6; *Khim. Referat. Zhur.* **2**, No. 3, 101(1939).—The stability of different cements to CO_2 and H_2S was investigated. The smallest gas permeability was shown by samples (from 1·3 solns.) prepd. with portland cement and the max. permeability by samples prepd. with the acid-resisting KTsV cement. CO_2 had a greater effect on the compressive strength than did H_2S. The samples prepd. with the acid-resisting cement were destroyed by the action of CO_2. Most of the other samples, after 28 days increased in strength under the action of CO_2. W. R. Henn

Cast blocks from aluminous slag for lining cement kilns. A. I. Zhilin and L. P. Ignat'eva. *Tsement* **6**, No. 6, 41–5(1939).—Blocks from aluminous blast-furnace slags contg. not over 39% of CaO are resistant to the effect of clinker, but have low spalling resistance. E. E. S.

Chromite-alumina [cement-kiln] lining. N. I. Levin and E. G. Kanovich. *Tsement* **6**, No. 8, 10–14(1939).—The use of chromite-alumina linings is effective at plants with average burning conditions. E. E. Stefanowsky

Properties of hydraulic blast-furnace slags. G. Mussgnug. *Arch. Eisenhuttenw.* **13**, 193–200(1939).—Because wide variations have been obtained in tests of slags that are almost identical physically and chemically, the more recent testing methods are reviewed and a modified method was developed. Setting-accelerators were investigated. Hydrated lime is the most important economically. KCl as accelerator gives the highest compression strength and KOH the highest bending strength in water; KCl increases shrinking considerably. Ability to set is greater, the higher the temp. at which the slag was blown. With increasing ratio of SiO_2 to Al_2O_3 the waterproofness increases, airproofness is unchanged, and shrinking decreases. A decreasing ratio favors setting of the slags in water and in air. A higher Mn content decreases setting power of the blast-furnace slags. The ratio $CaO:SiO_2$ has no practical effect on the mech. properties. A higher Al_2O_3 content favors in general the reactivity of a slag. Acid slags set less readily than do basic slags. M. H.

Lime paste from calcium carbide waste. I. Yu. Belyavskiĭ. *Keramika* **1939**, No. 4, 45.—Waste from acetylene generators, contg. up to 76% of CaO, gives in 28 days a strength exceeding that of usual lime-sand mortar (1:3 ratio). It contains no acetylene or H_2S NH_3 and very small amounts of PH_3 are present. E. E. Stefanowsky

The preparation of mortar from activated kaolin. Rudolf Barta. *Chem. Obzor* **14**, 212–13(1939).—Kaolin heated at 600–700° released a reactive form of SiO_2 which had the capacity of combining with the free lime in cements and improving their quality. The behavior of this kaolin is used to explain why flours prepd. from bricks—especially from bricks fired at low temps.—added to mortars gave such lasting qualities to Roman cements. The relation of this activated kaolin to the mortar "Ladco Bondo" of Cartersville, Ga., is discussed. F. Maresh

Method for estimating mixing water in the determination of mortar strength of sands. Horace A. Pratt. *Maine Tech. Expt. Sta., Univ. Maine*, Paper No. 26, 15 pp.(1939).—The proper amt. of water required for mixing mortars made with com. sands for the Maine State Highway Commission was at first obtained by trial and error within the approx. range of 10 to 14%. Multiple correlation studies showed that the amt. of mixing water was a function of the proportion of granitic grains present, the surface area of the grains, the percentage retained on the 28-mesh sieve and the fineness modulus. With the 3 regression equations developed, it is possible to est. with a considerable degree of accuracy the amt. of mixing water required for any Maine sand to produce a mortar of the required consistency. A. W. King

Laboratory tests of concretes and mortars exposed to weak acids. Dalton G. Miller, Philip W. Manson and Charles F. Rogers. *Agr. Eng.* **20**, 427–30(1939).—See *C. A.* **33**, 7069⁸. J. R. Adams

Testing the efficiency of concrete-curing methods. Henry D. Dewell. *Western Construction News* **14**, 403–5 (1939). George Ayers

Gas concretes from Moscow district coal ash. L. A. Kislyakov and N. N. Gureeva. *Keramika* **1939**, No. 4, 41–4.—Gas concretes were made by autoclaving, with an addn. of 0.1–0.2%, of aluminium powder, (*a*) lime, cement and ash and (*b*) lime and ash. The first was fairly strong and air-stable, the second less so. Floor blocks can be prepared from cementless gas concrete containing 3% of $CaCl_2$ as filler. The frost resistance is low. E. E. Stefanowsky

Portable apparatus for determining the relative wear resistance of concrete floors. Louis Schuman and John Tucker, Jr. *J. Research Natl. Bur. Standards* **23**, 549–70(1939)(Research Paper No. 1252).—The paper describes a portable abrasion machine and an optical gage for measuring the depths of wear. Abrasion tests were made on 138 slabs of portland cement mortars and concretes ranging from 1:2 to 1:3.6 mixts. with cement-water ratios from 1.33 to 2.50. The effects of other factors such as aggregate types, grading, finishing procedures, dust coats, liquid surface treatments, metallic hardeners, cement dust coats, delayed trowelling and increased wear resistance were also studied. Dry mixes, coarsely graded aggregates and adequate wet curing helped increase wear resistance. High early-strength cement mixts. required much shorter periods of damp curing without decreasing the wear resistance. A. W. King

The evaluation of fillers for tar and other bituminous surfacings. J. G. Mitchell and A. R. Lee. *J. Soc. Chem Ind.* **58**, 299–306(1939). Data are given showing that the bulk d. of a filler which has been allowed to settle in C_6H_6 gives a quant. measure for proportioning it as a constituent of a bituminous surfacing. For fillers which are not sol. in bituminous binders, the addn. of equal bulk vols. of different fillers to the same quantity of bituminous binder gives products having the same viscosity, irrespective of the nature of the filler. M. and L. also give data showing that adsorption between filler and binder causes removal of the resinous constituents from the binder and tends to reduce the viscosity of the product. Results from mech tests and early observations on full-scale road expts. also show that the bulk d. of a filler is its significant property in relation to bituminous road-surfacing materials, and that failure may easily occur through neglect to adjust the filler-binder ratio on this basis. M. and L. advocate the inclusion of a clause defining the relation between the bulk d. of the filler and the binder content in existing specifications for bituminous surfacings. H. Mare

Gypsum of the Porkhovo deposits. A local source of raw material for the building industry of Leningrad. I. G. Sandomirskiĭ. *Keramika* **1939**, No. 8, 33–6. E. E. S.

Gypsum and anhydrites of Bashkiria. S. P. Zorin. *Keramika* **1939**, No. 8, 37–41.—Characteristics are given of several kinds of gypsum and anhydrite and of anhydrite cement and slag blocks made from it. E. E. S.

Cellular gypsum from alabaster. A. B. Getselev. *Keramika* **1939**, No. 6, 45–50.—The process is similar to the production of froth concrete from portland cement. E. E. Stefanowsky

The methods of testing antiseptics in the control of house fungi. B. P. Karakourtin. *Sovet. Botan.* **2**, 57–65 (1939); *Rev. Applied Mycol.* **18**, 720.—The growth of *Merulius lacrymans* and *Coniophora cerebella* on wood was completely arrested by doses of anthracene oil of between 1 and 2% of the wt. of the wood, while 5% carbolineum (the largest concn. used) only retarded it slightly. Oden E. Sheppard

Minimizing shrinkage and swelling of timber. H. E. Desch. *Wood* **4**, 19–21(1939).—Impregnation of wood with chemicals reduces shrinkage and swelling in special circumstances, but the cost is too high for general application. For many uses, sufficient protection is obtained by protective coatings that merely offer mech. resistance to moisture movement. Leopold Scheflan

A new preservative. J. Bryan. *Wood* **4**, 161–2(1939).—In lab. tests, with 2 parts of $K_2Cr_2O_7$ to 1 part of $HgCl_2$

the chloride was fixed in the wood to the extent of 99%. The fixative action of the dichromate does not adversely affect the toxicity of $HgCl_2$. The soln. contg. 2% $K_2Cr_2O_7$ and 1% $HgCl_2$ while not so corrosive as $HgCl_2$ soln. alone is still too corrosive for use in ordinary metal containers. This corrosive action can be reduced by the addn. of reducing salts. Best results were obtained with $NaNO_2$. By the addn. of 5% of $NaNO_2$ the corrosion of Fe and steel was kept within normal limits experienced with water-sol. preservatives so that steel equipment can be used; however, Cu and brass vessels are attacked. The reduction of the dichromate by the nitrite is prevented by the addn. of 0.5% NaOH; excess base will cause pptn. The max. concn. suitable for industrial operation is $NaNO_2$ 1.25, $K_2Cr_2O_7$ 0.5, $HgCl_2$ 0.25, NaOH 0.125, H_2O 97.875 lbs. To prepg. this mixt. the alk. $NaNO_2$ soln. should be added slowly to a soln. of $HgCl_2$ and $K_2Cr_2O_7$. The same effect can be achieved by eliminating NaOH and using K_2CrO_4 in place of $K_2Cr_2O_7$. To obtain permanent protection from the use of this new preservative it is necessary to impregnate the timber under pressure. L. Scheflan

Fluorine compounds as wood preservative. D. Steinberg. *Can. Chem. Process Inds.* **23**, 601(1939).—A review of methods of application. NaF and some of the natural fluosilicates are the most important F compds. used as wood preservatives. Solns. of F compds. are generally applied in closed containers in which wood is treated with the soln. under pressure. W. H. Boynton

Pentachlorophenol for wood preservation. T. S. Carswell and Ira Hatfield. *Ind. Eng. Chem.* **31**, 1431–5 (1939); cf. C. *A.* **32**, 5531[2].—Lab. tests show that small amounts of pentachlorophenol in nutrient agar kill transplants of 21 different wood-destroying fungi while wood blocks treated with a 0.5% soln. of the chemical are resistant to 3 test organisms used. Its low soly. in water (8 parts per million at 50°F.) and its low vapor pressure (0.0017 mm. Hg at 20°) promise a high degree of permanence. Service tests have so far yielded favorable results. Its soly. in 26 org. solvents is given as well as a discussion of suitable methods of application. R. H. B.

Testing of timber preservation by laboratory methods. K. Rubanus. *Angew. Botan.* **19**, 579–86(1937).—The effectiveness of Basilit N extra, Basilit U and Basilit U A as wood-preserving materials was tested. In Basilit N the fungicidal ingredients are NaF and dinitrophenol. In Basilit U a Cr compd. is added, while Basilit U A contains, in addn., an As compd. The theory is that with Basilit U the Cr compd. is reduced in the wood and together with the fluoride will form new, complex salts not easily sol. in water; with Basilit U A, Cr-As compds. will form which are still more resistant to the dissolving action of water. The 3 materials were tested in the lab. In addition, these materials were tested out of doors, under every day conditions. Basilit U and Basilit U A proved superior to the older prepn. Basilit N extra. K. L.

Bleeding from creosoted sleepers treated by the Rueping process. A. D. Dhall. *Indian Forester* **65**, 349–55 (1939).—Deodar, fir and chir treated by the Rueping process lost on the first day an av. of 28, 20 and 4%, resp., of the material originally injected; 4, 3.5 and 0%, resp., on the 2nd day; 2, 0.7 and 0% on the 3rd day; 1, 0.7 and 0% on the 4th day; and 0.5, 0 and 0% on the 5th day. In summer deodar, fir and chir lost by bleeding as high as 15, 35 and 6%, resp., while in the winter as little as 25, 10 and 1% were lost, resp. The mechanism of bleeding and possible means of reducing it are discussed.

Colin W. Whittaker

App. for luminescence analysis and its use for examn. of silicates (Shvetsov, *et al.*) **1**.

Cement mixture. Henry H. Morcton. U. S. 2,176,862, Oct. 17. A mixt. of Portland cement, ground silica sand, pumicite, and a natural silicate product native to the Mojave Desert (which is a gel-forming colloidal material contg. approx. 14% of magnesia, of high water absorptiveness, and of an inherent alumina content of about 0.8% which is so low that the quantities of any aluminates or alumina-silicates which may be formed within the mixt. will be negligible) is suitable for making a cement of relatively low shrinkage and high strength.

Solidifying permeable rock and concrete layers, etc. Tore G. Malmberg. U. S. 2,176,266, Oct. 17. A process for tightening and consolidating rock formations, sand and gravel layers, porous concrete, dam structures, shafts and drill holes, etc., involves the step of prepg. an aq. mixt. of an alkali silicate and a water sol. acid salt of a weak acid, injecting the mixt. into the material to be treated prior to any appreciable coagulating reaction having taken place in the mixt., and letting the reaction between the alkali silicate and the acid salt proceed with a formation of silica gels in the injected material. Salts such as $NaHCO_3$ or borax, etc., may be used, also $NaHSO_3$, etc.

Bituminous paving material. James M. Johnson. U. S. 2,177,568, Oct. 24. A method of prepg. a bituminous paving material comprises segregating a mass of paving aggregate, adding thereto a mixt. of Al oleate, free oleic acid and light lubricating oil, in sufficient amt. thoroughly to coat the particles of aggregate therewith, while maintaining the mass in agitation, and, when the soap mixt. is uniformly distributed, adding the amt. of bituminous material required for the pavement and continuing the agitation until the bituminous material is evenly distributed over and around the particles of aggregate.

Aging calcined gypsum. Frank L. Marsh and Dudley C. Chads (to National Gypsum Co.). U. S. 2,177,668, Oct. 31. Calcined gypsum is agitated, exposed to a moisture-carrying gas such as air having a predetd. relative humidity, and this treatment is continued until rehydration to the hemihydrate is effected.

Saturating web materials as in treating roofing material with asphalt. Donald A. Cumler (to United States Gypsum Co.). U. S. 2,176,835, Oct. 17. App. is described, and a method for effecting optimum satn. which involves periodically exerting oppositely directed forces transversely of and substantially parallel to the broad surface of a web to cause alternately loosening and compacting of the fibers of the web while it is passing through a satg. medium.

Colored granular material suitable for use on asphalt roofing. Carl E. Hillers and Horatio L. Small (to Blue Ridge Slate Corp.). U. S. 2,177,389, Oct. 24. Granules such as those of slate are coated with Ba fluosilicate, an aq. dispersion of alkali metal silicate and a coloring material, and are heated (suitably to about 140–150°), soaked in water, rinsed and dried.

Flooring and roofing material, etc. James P. Burke (to Vermiculite Corp. of America). U. S. 2,177,092, Oct. 24. A fabric base such as burlap is provided with a layer of a substantially densified compn. of exfoliated vermiculite and a varnish binder applied to the base and having an exposed surface. U. S. 2,177,093 describes app. and the manuf. of a roof covering comprising a metallic base, a layer of exfoliated vermiculite and a varnish having a relatively high percentage of voids therein and a superposed layer of waterproof material such as an asphaltic compn.

Tiling suitable for flooring. Herbert A. Winkelmann (to Marbon Corp.). U. S. 2,177,413, Oct. 24. Tiles of substantial thickness are formed with fillers and a binder including a rubber-HCl and a soap such as Ca stearate, etc.

Wall plaster. Walter A. Troy. U. S. 2,176,938, Oct. 24. A plastered wall highly resistant to cracking when subjected to stresses of compression or tension and by freedom from spalling under impact or when nails are driven into or withdrawn from it comprises a tough, resilient, nail penetrable plaster compn. composed essentially of a hydraulic cement, sand and a fibrous material and having the outer surface portion impregnated with a solidified re-enforcing agent comprising Chinawood oil.

Light weight calcium sulfate plaster. Winfield W. Heckert (to E. I. du Pont de Nemours & Co.). U. S. 2,177,254, Oct. 24. Crushed gypsum rock calcined to a state of

hydration not higher than the hemihydrate, is mixed, in the presence of an acidic agent adapted for decompg. reaction with impurities in the gypsum, with a considerable excess of water over that required to rehydrate the hemihydrate and sufficient to form a slurry with the sulfate, the wet mixt. is agitated until the calcined material has crystd. in a finer particle size and in the dihydrate form, and the material is recalcined to an anhyd. dead burned form. Various crystal growth restraining agents may be used.

Floor-covering material. John J. Bradley, Jr., and Arthur R. Cripps (to Bird & Son, Inc.). U. S. 2,177,634, Oct. 31. A hard-surfaced floor covering is produced by a method which involves first forming an aq. mixt. including finely powd. wood, an aq. gel-forming emulsifying agent such as clay, soap or casein, and a substantial quantity of water, the gel-forming agent being present in sufficient quantity to hold practically all of the water, the mixt. having lubricating character, then applying to a flexible base such as asphalt-satd. felt a layer of the mixt. of substantial thickness, drying off the water from the layer to provide a smooth-surfaced though porous firm and adherent layer consisting mainly of the powd. wood and emulsifying agent on the base, and then applying coloring and binding material such as a lacquer compn. to fill the pores through at least the major portion of the depth of the layer.

Bleaching wood veneer. Russell Fortune. U. S. 2,176,763, Oct. 17. Wood veneer such as that of American maple is treated with an aq. alk. soln. contg. Cl, to remove natural pigment color without disturbing the fiber organization of the wood.

Treating veneers prior to gluing. Frank V. Tischer (to Anna M. Tischer). U. S. 2,177,160, Oct. 24. For rendering contained hygroscopic matter nonhygroscopic, both sides of a veneer are coated with a compn. including a neutralized oxidizing agent such as $K_2Cr_2O_7$ with Na_2CO_3, NaCl and glue, the coated veneer is dried, and then separately subjected to heat and pressure to cause the oxidizing agent to penetrate the veneer and act upon the hygroscopic matter.

Colored fiberboard. Joseph W. Gill (to United States Gypsum Co.). U. S. 2,176,854, Oct. 17. A colored fiberboard which is suitable for building purposes is formed of ingredients such as vegetable fibers, *e. g.*, those of cottonwood 1000 lb., size 5–15 lb., Brilliant Paper Yellow dye 6.5–8 oz., Brilliant Crocein dye 5–5.5 oz., nigrosine 2.5–4 oz., red oxide of Fe 4–15 lb., carbon black 3–3.5 lb. and alum 20–40 lb.

Wood-preservative composition. Howard B. Carpenter (to Penola, Inc.). U. S. 2,177,448, Oct. 24. See Brit 498,336 (*C. A.* **33**, 4402[8]).

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE SIERN

Spectral analysis of fuels. A. S. Elinger. *Tekhnika Vozdushnogo Flota* **1938**, No. 12, 71–5; *Khim. Referat. Zhur.* **2**, No. 4, 81(1939).—A short description of the general principles of the methods used for the detn. of hydrocarbons by means of infrared and of combination spectra. These methods developed by E. Cotton, Ober, Lecompte, Andant, Barshevits and Freiman are especially suitable for the analysis of gasolines. They make possible the detn. of all isomers of the individual hydrocarbons. Definite references to the chem. literature are not given.
W. R. Henn

Use of gas as a fuel for motor vehicles. J. S. Clarke. *Gas J.* **228**, 614, 617–18, 623(1939).—The compressor is 6
the essential mechanism in the compressed gas system. Up to 5000 lb. per sq. in. a 4- or 6-stage compressor may be used. The 4-stage is cheaper in cost, but absorbs about 35% more power. Tests on a single-cylinder Tangye engine with a direct injection combustion chamber have shown that a high brake mean effective pressure can be maintained with accompanying high thermal efficiency with a min. quantity of oil, the remaining part of the charge being town gas, without unduly high max. pressures being 7
developed. P. J. Wilson, Jr.

High octane aviation fuel by the sulfuric acid alkylation process. S. H. McAllister. *Refiner Natural Gasoline Mfr.* **18**, 494–503(1939); *Natl. Petroleum News* **31**, R-512–16 (1939).—Olefins from C_3 to C_5 inclusive and isobutane or isopentane are mixed with H_2SO_4 and thoroughly agitated. The important variables are the isoparaffin-olefin ratio, 8
contact time, acid strength, temp., acid-hydrocarbon ratio, olefin concn. of the feed, and agitation. Standard com. equipment may be used. The acid loses titratable acidity by the absorption of hydrocarbons, but may be recouped by conventional methods. The products are of a completely isoparaffinic nature and have a high octane no. (82 to 93), high lead susceptibility, very low S content and high calorific value. The product boils in the gasoline range and is good blending stock for 100-octane no. aviation fuel. The process produces 2½ to 5 times as 9
much 87-octane no. aviation fuel as do the polymerization processes when operating on a C_4 fraction from cracking. 5 references. C. H. Brooks

Thermal alkylation and neohexane. G. G. Oberfell and Fred E. Frey. *Refiner Natural Gasoline Mfr.* **18**, 486–93, 503(1939); *Natl. Petroleum News* **31**, R-502–9(1939).—With much the same charging stock, alkylation produces a more volatile material than does polymerization. Thermal alkylation is less selective as regards charging stock than is acid alkylation. In the manuf. of neohexane, an ethane-propane mixt. is cracked at low pressure and 1425°F. to give the max. amt. of ethylene. The ethylene is absorbed in liquid isobutane and distributed to 10 points along a pipe coil, through which more isobutane is pumped. A temp. of 950°F. and a pressure of 3000 to 5000 lb. per sq. in. are maintained in the reaction zone. The liquid products are sepd. by conventional fractionation. The lead susceptibility of neohexane is better than that of synthetic isooctane. Data are included on volatility and lead susceptibility of neohexane, and blends of isooctane-heptane, neohexane-isooctane, and isopentane-isooctane, as well as data on aviation-fuel blend. 18 references. C. H. Brooks

Engine combustion and pressure development. Effects of mixture ratio, spark position and throttle opening on flame pictures and pressure cards. Gerald M. Rassweiler, Lloyd Withrow and Walter Cornelius. *S. A. E. Journal* **46**, 25–48T(1940); cf. *C. A.* **30**, 5774[8]; **32**, 6033[3].—Values of either vol. or mass fraction of charge inflamed at any time as calcd. from the pressure record are in close agreement with the same values calcd. from analysis of 38 different high-speed motion pictures of the flames. A 900-r. p. m. single-cylinder L-head engine with unheated intake was used, with 3 spark locations, 2 spark advances and full or part throttle opening, at 4.6–4.8 compression ratio and 13–19 air/fuel ratio, and with gasoline or isooctane as the fuel; no knock was observed. The effects of these variables on the combustion process and pressure development are pointed out. Even under the engine conditions used, there appears to be no marked stratification of the charge, and it is likely that the method of calcn. can be applied to automobile engines. H. A. Beatty

Dangerous swelling pressures in carbonization practice G. E. Foxwell. *Gas World* **111**, No. 2887 Coking Sect., 141–2(1939); cf. *C. A.* **34**, 239[9]. P. J. Wilson, Jr.

Problems which deserve consideration. W. H. Bristow. *Gas J.* **228**, 288–90(1939).—The production of some *coal products* which are important to the fuel and heavy industries are briefly reviewed. P. J. Wilson, Jr.

Chemical research and coal. Jessie V. Sullivan. *Mfrs. Record* **108**, No. 10, 30, 52(1939).—A survey. L. S.

The coal production of Hungary. István Vitális. *Math. naturw. Anz. ung. Akad. Wiss.* **58**, 619–35(1939); cf. *C. A.* **33**, 4764[8].—The output of coal was 159,604 metric tons in 1851, 737,140 in 1867, 4,894,353 tons in

1896, 10,274,052 tons in 1913 and 9,359,704 tons in 1938. The total output from 1841 to 1938 amounts to 386 million tons, 18% of which was black coal and 82% brown coal. The proportion of black coal decreased in 1938 to 11.1%. S. S. de Finály

The thermal behavior of coal. I. The behavior of coals in heating to incipient softening. Horst Brückner. *Angew. Chem.* **52**, 671–6(1939).—A comprehensive summary with data, diagrams and 50 references. K. K.

Hydrogenation of typical North American splint coals. Abner Eisner, Geo. C. Sprunk, Loyal Clarke, C. H. Fisher and H. H. Storch. *Ind. Eng. Chem.* **32**, 73–8(1940), cf. *C. A.* **33**, 9587⁸.—American splint coals are similar to European splint coals in being less suitable for hydrogenation than bright coals. The liquefaction yields of 12 splint samples were found to be inversely proportional to both the C and opaque matter contents. The hydrogenation residues were opaque, which indicates that spores, resins and other translucent constituents had been liquefied. Joseph H. Wells

The ash constituents of Hungarian coals. Elemér Vadasz *Bányász. Kohász. Lapok* **72**, 387–90(1939).—The ash components of coal are detd., not by the ash of the plant from which the coal was formed, but by the components of the sedimentary rocks and the neighboring substances, and are thus independent of the geological age of the coal. Numerous analyses of Hungarian coal ash are given. S. S. de Finály

The determination of the fusibility of coal ash. G. E. Hall *Gas World* **111**, No. 2887 Coking Sect., 134–9, 1939). H. discusses methods of detn. and evaluates factors affecting the results. Conclusions: A direct test is the only means available for detn. of the fusion point or softening interval of the ash; analysis gives no indication of the probable values. Most authorities consider a cone method to be the most satisfactory. The control of atm. in the test furnace is of paramount importance. A mildly reducing atm. in which the ratio of the vols. of oxidizing to reducing gases falls between the limits 20 80 and 80 20 is generally considered most satisfactory. P. J. W., Jr.

Cracking tars and distillates from coal. Gustav Egloff, Jacque C. Morrell, G. B. Zimmerman and W. E. Lemen. *Ind. Eng. Chem.* **32**, 39–47(1940).—Coal tars, creosote oils, lignite tar fractions and distillates from the low-temp. carbonization of coal-oil mixts. are cracked under conditions to produce gasoline, gas and coke or fuel-oil residues. The boiling phenols are produced from higher-boiling tar acids. Com. products include finished gasoline, cresylic acid, fuel oil, domestic coke, electrode C and polymer gasoline. In comparison with petroleum cracking, greater corrosion is encountered and lower plant capacities are obtained. The finished gasoline has a greater heating value per unit vol. with good antiknock value. The gas is lower in mol. wt. and heating value than that from petroleum cracking. Joseph H. Wells

Oil dehydration of North American lignites. E. P. Schoch *Ind. Eng. Chem.* **31**, 1489–96(1939); cf. *C. A.* **33**, 7990⁸.—The lignite was dehydrated by covering with naphtha (b. 160°), heating to 210° in a closed vessel and allowing the liberated H_2O to escape slowly. The oil was then removed by drainage followed by a brief reduction of the pressure to 15 mm. This treatment did not disintegrate the original lumps. The product (4% moisture) had a heating power of 11,000 B. t. u. A. M. Collins

Gasoline from peat tar. N. S. Semenov and M. K. Kompanets. *Motor* **16**, No. 4, 24–8(1938).—A graphical comparison is given of the behavior of gasolines from oil and peat tar in an automobile engine. The octane no. of the petroleum gasoline was 63 while those of the peat-tar gasolines were 70.5 and 63.0 while their initial b. ps. were 90° and 120°. At 1000 r. p. m. the first peat gasoline developed 0.2–0.3 more h. p. than the oil gasoline while the second gasoline developed a lower h. p. It is necessary to add about 10–12% of ordinary gasoline to the peat gasolines to bring their starting properties up to satisfactory standards. B. Z. Kamich

Dry purification of gas. M. G. Kazhdan and V. G. Bocharov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 54–6(1939).—When coke gas is passed through finely divided coke at 18–33°, the H_2S and tar droplets in it are removed. H. M. Leicester

Purification of [fuel] gases. Kenzi Nakamura. *J. Fuel Soc. Japan* **18**, 843–52(1939).—A general discussion. F. I. Nakamura

Wood gas. G. H. Donald. *Wood* **4**, 80–2(1939).—An illustrated discussion of the production of producer gas from wood and its application in the driving of automobiles. Leopold Scheflan

Yield of chemical substances during the gasification of wood in a Siemens gas generator. N. V. Chalov. *Lesokhim. Prom.* **6**, No. 2, 26–8(1938); *Khim. Referat. Zhur.* **2**, No. 3, 124(1939); cf. *C. A.* **32**, 5187⁴.—At the gas-generating station of the Bytoshev glass plant (hardwood logs are used for fuel) samples of the steam-gas mixts. were analyzed for tars, HCOOH, CH_3COOH, C_2H_5COOH, aldehydes, CH_3OH, ketones, esters and unsatd. alcs. The yield of all products (excepting the tar) was only one-half of that usually obtained during dry distn. The insides of the logs burn before they are decompd. In the gasification of chips in the generator AVG the yield of the products was much higher. W. R. Henn

Induced pyrolysis of methane. W. J. Hessels, D. W. van Krevelen and H. I. Waterman. *J. Soc. Chem. Ind.* **58**, 323–7(1939); cf. Fischer *C. A.* **27**, 2016; Peters and Meyer, *C. A.* **24**, 484; Tropsch and Egloff, *C. A.* **29**, 7355⁷.—The pyrolysis of CH_4 in the presence of foreign substances, such as halogens, aliphatic hydrocarbons (I) and halogen, S or O compd. of I as inductor, is studied. The primary reaction in the pyrolysis is the formation of radicals which react with each other and with undecompd. CH_4. The same radicals are also formed by the action of halogens on CH_4 or by the thermal decompn. of I which are less stable than CH_4 itself. I, such as C_3H_8 or C_4H_{10}, can be used for the production of the radicals necessary to demonstrate the induction effect on the CH_4 pyrolysis. By applying the inductor effect of foreign substances CH_4 is transformed into unsatd. hydrocarbons such as C_2H_4, C_2H_2, C_6H_6 and naphthalene under conditions where CH_4 alone passes the heating zone unchanged. The ratio of CH_4 to inductor is important and the effect is more marked if the concn. of the inductor is low in comparison with the CH_4 concn. Aromatic compds. such as C_6H_6 and naphthalene have very little or no induction effect. When the gases are passed through the furnace several times, high yields of conversion products are obtained and unsatd. I formed in the first passage through the heated tube act as inductor in the next passage. The induced pyrolysis can be applied to CH_4 present in natural gases which usually contain substances capable of acting as inductors. It has been shown that by the decompn. of the higher I in natural gas, CH_4 can be partially involved in the decompn. under conditions in which pure CH_4 undergoes no decompn. F. E. Brauns

Dry quenching of coke. A. Furman. *Novosti Tekhniki* **1939**, No. 23/24, 50–1.—In the first expts. on dry quenching of coke in the Soviet Union the porosity, true and apparent sp. gr., and elec. cond. of the dry-quenched coke were the same as those of wet-quenched coke. The dry-quenched coke had a greater content of large fractions, more moisture, less S, and less volatile compds. than wet-quenched coke. B. Z. Kamich

Optimum dimensions of the newest-design coke ovens. A. S. Vodyanoi. *Coke and Chem.* (U. S. S. R.) **1938**, No. 7, 43–5; *Khim. Referat. Zhur.* **2**, No. 2, 133–4(1939).—The construction and the dimensions of coke ovens in different countries are compared and discussed. In the new project of coke ovens of the "Giprokoks" system the thickness of the brick wall along the whole height is 110 mm.; this can be reduced to 100 mm. W. R. Henn

Hot repair of coke ovens. V. A. Bron. *Ukrain. Nauch.-Issledovatel. Inst. Ogneuporov i Kislotouporov* No. **45**, 58–72(1939).—Attempts to produce suitable mixes for hot repair of coke ovens are discussed. The most suitable mix was found to be that composed of natural dust-like quartz rock (called marshalite), as a basic component and

addns. of 20% finely ground quartz and 5% Chassov Yar clay, and 1.0% to 1.5% graphite and 1.25% sol. glass. M. V. Condoide

Siberian petroleum--brown coals of Krivorog District (Naida) **22**. Detn. of compn. diagram for liquid-gas system CH_4 N H [calcns. for fractionation of coke gas] (Shtekkel, Tain) **2**. Traces of Cu and Fe in alc. [keeping qualities of motor fuel] (Knop, Mahler) **16**. Effect of steam on silica brick for coke ovens (Herman) **19**. Purification of phenol waste waters by activated C (Kozko) **14**. Purification of waters from peat-gas generators (Ruff, Martynova) **14**. Organic acids from oxidation of coal, coke, etc. (U. S. pat. 2,176,343) **10**. Removing gyp scale from gas wells (U. S. pat. 2,177,345) **22**. Removing volatiles from coal (U. S. pat. 2,177,665) **22**.

Motor fuel mixtures. Helmuth G. Schneider and Wm. H. Smyers (to Standard Oil Development Co.). U. S. 2,176,717, Oct. 17. A motor fuel of high octane no. contains about 75% of a light hydrocarbon liquid such as petroleum naphtha and about 25% of methyl propyl ketone or other ketone having not more than 10 C atoms, and a small amt. of a tetraalkyl or tetraaryl Pb compd. serving as an antiknock constituent. Cf. *C. A.* **33**, 5644[9]. 3

Motor fuel from normally gaseous hydrocarbons. Wm. M. Stratford (to Texas Co.). U. S. 2,177,421, Oct. 24. An arrangement of app. is described, and a process which involves preheating a hydrocarbon gas predominating in paraffinic hydrocarbons to a temp. short of active conversion thereof while at an elevated superatm. pressure, substantially instantaneously heating the preheated gases to a sufficiently elevated temp. while under elevated superatm. pressure rapidly to convert paraffinic hydrocarbons to olefinic hydrocarbons, cooling the resultant gaseous products, polymerizing olefinic hydrocarbons thus produced and cooled while under elevated superatm. pressure to liquid hydrocarbons contg. motor fuel, and sepg. and recovering motor fuel from the products of polymerization. 4

Diesel fuel. Wm. H. James, Robert C. Moran and Edwin M. Nygaard (to Socony-Vacuum Oil Co.). U. S. 2,177,719, Oct. 31. A hydrocarbon fuel oil is mixed with about 1 5% of bis (diamylamine) disulfide to decrease the ignition delay period of the fuel. 5

Diesel engine fuel. Frederick H. MacLaren (to Standard Oil Co. of Ind.). U. S. 2,177,732, Oct. 31. A method of increasing the pour point susceptibility of a narrow-cut high-speed Diesel engine fuel oil having an initial b. p. of about 200–260°, an end point of about 315–270°, and characterized by a difference in temp. between the 50% distn. point and the 90% distn. point of less than about 30°, the pour point of which is normally not materially reduced by the addition of a pour-point depressor, involves adding to such fuel oil about 0.2–2% of a pour-point depressor such as a condensation product from naphthalene and chlorinated paraffin wax and about 0.2–0.8% of an amorphous waxy material such as petrolatum or wax tailings, by which the pour point is materially reduced. 7

Diesel engine fuel production by cracking petroleum residues. Jacque C. Morrell (to Universal Oil Products Co.). U. S. 2,176,353, Oct. 17. An arrangement of app. is described, and a process for producing Diesel engine fuel and fuel for spark ignition engines from paraffinic and mixed base residues heavier than gas oil, which comprises subjecting such residue to a temp. of from about 510° to 590° for a cracking time of the order of less than 5 sec., sepg. resultant vapors from unvaporized oil, fractionally condensing the vapors to form a condensate of hydrocarbons heavier than gasoline and removing this condensate from the process, subjecting the unvaporized oil to a temp. of about 455–510° for about 10 to 40 sec. to convert a substantial portion thereof into gasoline, fractionating the vapors formed by the last-named cracking treatment to condense fractions thereof heavier than gasoline, and finally condensing and collecting the fractionated vapors. 8

Apparatus for gasifying liquid or plastic fuels such as hydrocarbon fuels. Chester A. Killmeyer and Geo. L. Reichhelm (to Frank A. Kane). U. S. 2,176,305, Oct. 17. Various structural and operative details. 9

Fuel-conditioning and -burning apparatus for conjoint use of pulverized and liquid fuels. Webster I. Salley. U. S. 2,176,824, Oct. 17. Various details of app. suitable for conjoint use of pulverized, liquid and gaseous fuels.

Tunnel furnace for distillation, coking and drying purposes. Peter Scheloumow (to Eesti Patendi Aktsiaselts). U. S. 2,176,825, Oct. 17. Various structural and operative details of a furnace suitable for distg. bituminous materials.

Coating solid fuels such as coal with petrolatum, etc. Harvey R. Fife. U. S. 2,176,128, Oct. 17. App. is described, and a method of protectively coating solid fuel susceptible to dusting and degradation which comprises forming a mixture of petrolatum and water, applying an extraneous mech. pressure to the mixt. of petrolatum and water, heating the mixt. while it is subjected to such pressure to a temp. adequate to liquefy the petrolatum and above the b. p. of the water for conversion of the water to steam upon release of the pressure, and passing the mixt. through a spraying nozzle under the combined extraneous mech. pressure and the vapor pressure of the heated liquid, while the hot spray is directed on the coal. U. S. 2,176,12[9] relates to a method of protectively treating coal with oily petroleum material which comprises atomizing an oily petroleum material into a fine mist by subjecting it to extraneous mech. pressure at a spray nozzle, and while the coal to be treated is passed through a treating zone of the finely atomized mist, steam is added independently at low velocity and low temp. to the finely atomized mist, to supply to the coal independently of the mist heat for flowing the oily petroleum material of the mist over the coal and to apply moisture at the surface of the coal.

Coating coal with oil, etc. Harvey R. Fife. U. S. 2,176,127, Oct. 17. A petroleum blend for dust-proofing and otherwise protectively treating coal and coal-derived particulate fuel consists substantially of petroleum oil, having in application to the fuel a fluidity corresponding to that of a Pennsylvania petroleum-derived oil within the approx. viscosity range of 50 Saybolt sec. at 38° and 15[0] Saybolt sec. at 38°, charged with a substantial content of amorphous petroleum wax, the petroleum oil constituting not less than 75% of the blend, and the blend having a viscosity below 38 Ford cup sec. at 58°.

Apparatus for separating crude coal, slate, etc., by water currents. Frank E. Smith (to E. I. du Pont de Nemours & Co.). U. S. 2,176,107, Oct. 17. Various structural and operative details.

Removing gaseous weak acids such as H_2S and CO from gases such as coal hydrogenation waste gases. Heinrich Ulrich, Reinhold Fick, Hans Baehr and Wilhelm Wenzel (to I. G. Farbenind. A.-G.). U. S. 2,176,111, Oct. 17. The gas is scrubbed with a soln. of Na diethylenetriamino-diacetate or other salt of an alkali, alk. earth or strong org. base with an aminocarboxylic acid contg. at least 2 N atoms and derived from ethylenediamine or a polymer (the salt used having an alk. reaction).

Gas from finely divided fuels such as oil or pulverized coal. Claude C. Van Nuys (to Air Reduction Co.). U. S. 2,177,379, Oct. 24. App. is described, and a method of producing gas of high calorific value from finely divided fuels which involves projecting the fuel and O in opposed co-axial jets, the fuel being in excess of the amt. which will react with the O supplied, maintaining combustion at the zone where the opposing jets collide and exclude steam, and simultaneously introducing steam in the region surrounding the jets for reaction with highly heated surplus fuel which is not burned with O.

Removing moisture and acid gases from natural gas, etc. Arthur J. L. Hutchinson (50% each to The Fluor Corp., Ltd. and Lone Star Gas Co.). U. S. 2,177,06[8], Oct. 24. An arrangement of app. is described, and a process of purifying a gas contg. water vapor and H_2S or CO_2 as impurities, that includes bringing the gas into contact with an absorbent composed of a liquid polyhydric alc., an aliphatic amine, and water, the amt. of polyhydric

ale. being substantially in excess of the amt. of aliphatic amine, and regenerating the fouled absorbent by heating it sufficiently to sep. the absorbed water vapor and acidic gases therefrom.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STEWART S. KURTZ, JR.

Siberian petroleum. V. M. Senyukov and A. A. Shmelev. *Soviet Geol.* **9**, No. 8, 83-4(1939). **Petroleum content of the Upper Paleozoic deposits of the Eastern European Platform.** M. M. Tolstikhina. *Ibid.* 85-6. **Brown coals of the Krivorog District.** M. I. Naida. *Ibid.* 86-90. **Crystalline shales of the Main Caucasus Divide and their origin.** S. P. Solov'ev. *Ibid.* 90-1.
F. H. Rathmann

Desulfurization of Kalin petroleum. Sh. B. Aliev. *Izvest. Azerbaĭdzhan. Filiala Akad. Nauk S. S. S. R.* **1938**, No. 2, 75-9; *Khim. Referat. Zhur.* **2**, No. 3, 108(1939).—The treatment of the Kalin petroleum (0.31-0.39% of S, 7% of water) with pyrite slags for 24 hrs. on a water bath did not give pos. results. The S content was lowered by 33% in the preliminarily dried petroleum which was treated with roasted slags for 8 hrs. at 160-70°. It was not possible to obtain a complete desulfurization of the Kalin petroleum. W. R. Henn

A solid naphthenic acid from Iranian petroleum. Thomas Kennedy. *Nature* **144**, 832(1939).—From the caustic washing liquors used in removing traces of acid from a kerosene SO_2 ext. derived from Iranian petroleum, there was obtained a cryst. naphthenic acid. After repeated crystns. the acid m. 82°, 70.9% C, 10.74% H (calcd. for $C_{10}H_{18}O_2$, 70.52% C, 10.66% H), mol. wt. by titration 173. A polymethylcyclopentyl structure such as

$CH_2.CMe_2.CHMe.CH_2.CMeCO_2H$

is suggested for the acid. It was obtained in 3.3% yield of the original acid mixt. from the caustic washing liquors. Rachel Brown

Synthetic fats from petroleum suitable for grease making. A. W. Burwell and J. A. Camelford. *Natl. Petroleum News* **31**, R-424-7(1939).—Saponifiable materials, ranging from C_6 to C_{24}, were prepd. by the controlled oxidation of petroleum distillates and waxes. They consist of a mixt. of acids, esters, lactones, alc. ketones, and primary, secondary and tertiary alcs. The soaps of Na, Ca, Al, Pb, K, Mg and Ba and the corresponding greases, were prepd., following the conventional outline, with only minor exceptions. C. H. Brooks

Condensers containing mineral oil and chlorinated aromatic compounds. M. G. Gertsenshtein and S. L. Sokolova. *Elektrichestvo* **60**, No. 3, 35-9(1939).—Data are given on the performance of condensers contg. mineral oil and Sovol (chiefly pentachlorodiphenyl). With rising temp. the tangent of the angle of dielec. losses in condensers contg. Sovol decreased and reached a min. of about 0.1 at 30-35° and then increased to 0.35 at 90°. For mineral oil the tangent was also at a min. at 30-35° but slightly higher (0.15) and at 70° it was 0.2. At 15-20° both condensers showed nearly the same tangent. The elec. properties of Sovol were reduced by the presence of rubber. After 8 months' use the Sovol condensers showed no change in the curves of tangent of angle of losses to voltage whereas for mineral oils the curves were U-shaped with the min. corresponding to the operating voltages. B. Z. Kamich

Improved equipment reduces water requirements at refineries. James M. Augustus and David S. Frank. *Natl. Petroleum News* **31**, R-454-6(1939).—The use of cooling towers or spray ponds may reduce the water requirement for a refinery to 25-30% of that formerly needed. All the water should be treated for use as a cooling medium. The quantities needed for special purposes, such as steam generation, can be drawn from the general system and treated. Examples, with analyses, of typical waters and their treatment are given. C. H. Brooks

Measurement of metal temperatures of cracking still tubes. O. G. Kaasa. *Natl. Petroleum News* **31**, R-478-80(1939).—A No. 8 constantin wire is peened into the surface of the fire side of the heater tube. A 1/2 in. calorized steel protecting tube, with the end shaped for welding to the heater tube, is insulated from the wire with asbestos cord covered with high-temp. shellac. The advantages are the ability to use standard iron-constantin calibrated instruments, the self-supporting nature of the installation, and complete protection from flue gas. The life of the installation is a year or more. C. H. Brooks

Catalytic reforming for the production of aviation gasoline. A. G. Peterkin, John R. Bates and H. P. Broom. *Refiner Natural Gasoline Mfr.* **18**, 501-8(1939); *Natl. Petroleum News* **31**, R-517-19(1939).—Gasolines or naphthas boiling up to 500°F. may be catalytically reformed to give aviation naphthas. The equipment and operation are similar to those of the Houdry catalytic cracking process (cf. *C. A.* **33**, 4005[1]). Installation costs are given. The operating costs compare favorably with those for thermal reforming. The product has a high octane no., good lead susceptibility, and stable antiknock properties under severe engine conditions. The same equipment can be used to produce aviation or motor fuels from naphthas, and aviation or motor fuels from gas oils. The yields are, resp., 30 to 60%, 83 to 94%, 35 to 40% and 50 to 56%. C. H. Brooks

Production of motor fuel from Udino shale oil. Domenico Costa. *Chimica e industria* (Italy) **21**, 609-12 (1939).—These shales contain high amts. of S, making it impractical to produce motor fuels by simple distn. However, on hydrogenation, the light fractions yield oils of low I_2 no., almost free of S; they give promise as motor fuels. A. W. Contieri

Combustion in the gasoline engine. T. A. Boyd, Lloyd Withrow and Gerald M. Rassweiler. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 566-77(1937)(in English).—In a summary of the phases of research conducted on combustion in gasoline engines, the app. and methods used in obtaining data on motor-fuel combustion within the engine are briefly described. A more detailed explanation is given of velocity of flame propagation, detonation, effect of antiknock agents, etc. 19 references. E. J. Mahler

Stoichiometric calculations of exhaust gas. G. W. Gleeson and F. W. Woodfield, Jr. *Natl. Petroleum News* **31**, R-461-4(1939); cf. *C. A.* **30**, 3204[6].—Equations are developed for calcg. the compn. of the exhaust gas from a motor. These include the equil. consts. for the water-gas reaction and the dissocn. of H_2O vapor, the air-fuel ratio, and the C, H and O in the fuel, as variables. Calcd. and exptl. results with pure octane and a blend of 20% EtOH and 80% isoöctane agree within about 20%. 10 references. C. H. Brooks

Ten-year trial shows success of inert-gas system. M. G. VanVoorhis. *Natl. Petroleum News* **31**, R-441-7 (1939).—The use of flue gas is superior to other methods of preventing the formation of explosive mixts. in refinery equipment and tank ships. Illustrations of some equipment are given. C. H. Brooks

Cylinder lubricating oils for locomotives operating under high heat conditions. Guillermart, P. Woog, J. Givaudon, Chmelevsky and Schmitt. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 536-56(1937)(in French).—Fourteen cylinder lubricating oils for locomotives operating under superheat conditions were tested in the lab. for stability. Locomotive tests were also run on those lubricating oils ranking high, and those ranking low in stability. High lab. stability was no indication of stability in practice. The I no. of lubricating oils is a good index of the lubricating quality, an oil with a low I no. being emulsified quickly on the hot cylinders without being previously satd. with water, and remaining stable. Tabulated results are given.
E. J. Mahler

The significance of vegetable oils as lubricants. István Thamm. *Anyagvizsgálók Közlönye* **17**, 57-77(1939).—High cohesion of vegetable oils diminishes friction and retards wear. This explains why the addn. of small amounts had good effects in practical lubricating expts. Vegetable oils are much less stable than mineral oils. The oxidation of lubricants contg. vegetable oil was investigated by a special Thamm-Freund app. The increase of viscosity at the end of the expts. was 7–12% in mineral oils, 26% in rape oil and 41% in castor oil which had been previously treated by chemical agents to make it sol. in mineral oils. Motors cannot be operated for more than 40–60 hrs. with lubricants contg. 30% vegetable oil. Addn. of suitable chemical inhibitors preventing rapid oxidation increases this period somewhat. S. S. de Finály

Influence of lubricants on the starting of motors. K. Schwaiger. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 529–35(1937)(in German).—The factors detd. by the lubricating oil were first established by motor research and the values obtained were compared with those resulting from cold viscometer tests. The tests show good agreement. It was shown that change in viscosity of many lubricants in the temp. range below 10° does not correspond to the accepted formulas. Graphs, illustrations and a diagrammatic representation of the cold viscometer are given. E. J. Mahler

Electroconvective vortexes in insulating liquids. Douchan Avsec. *Compt. rend.* **209**, 750–2(1939); cf. *Ibid.* **204**, 757(1937) and Hofmann, *C. A.* **29**, 2038⁶.—The electroconvective vortexes that appear momentarily in a film of lubricating oil (e. g., Shell B. 14), 2–35 mm. thick and spread over the glass bottom of a vessel 18 cm. diam., the sides of which are of paraffin, when subjected to a strong elec. field, are figured and described. C. A. S.

New method of purifying lubricating oils. Douchan Avsec. *Compt. rend.* **209**, 830–2(1939); cf. preceding abstr.—The production of instantaneous electroconvective vortexes in a film of lubricating oil (e. g., Shell B. 14, which is black, viscous and contains many particles) spread on glass and not confined by paraffin boundaries, on application of a strong elec. field by means of a pointed electrode charged at 50,000 v., and situated above the film causes the film to spread. At the same time the suspended particles are given to the periphery of the film leaving the oil in the center clear and transparent. On removing the field the particles diffuse back as they were. If the film rests on an earthed metal plate the vortices continue while the field is applied but interposition of a nonconducting substance between the charged point and the film causes the vortexes to cease over the shaded portion the extent of which is exactly as though the point were a source of light, while the particles accumulate, at the edge of the shadow next the "illuminated" portion, which remains free of particles. C. A. Silberrad

Insulating oils of high stability and low dielectric losses. R. M. Sitskaya, L. N. Aleksandriĭskaya, Yu. V. Koritskiĭ and V. V. Skipetrov. *Elektrichestvo* **59**, No. 12, 34–6(1938).—The Sligh nos. of Baku and Emba insulating oils which were refined with 9% H_2SO_4 and brought into contact with Zikeev earth at 90–95° were reduced to 13.6 and 14.0, resp. For Baku oil the lowest value of the tangent of the angle of dielec. losses (tg δ) was obtained after an acid wash with 14% H_2SO_4, the tangent changed very little at 20–80° and at 80° it was not over 0.0003, for the Emba oil the min. value of the angle of losses was obtained with 9% H_2SO_4. Some of the original oils were refined with selective solvents and brought into contact with Zikeev earth at 95°. For Baku oil, treatment with 200% furfural gave a Sligh no. of 7.7, acid no. of 0.005 and tg δ at 80° of 0.0009 while for Emba oil the resp. values were 12.0, 0.017 and 0.0007. Nitrobenzene gave better results when used in amts. of 300%, giving a tg δ of 0.0002 and a Sligh no. of zero for Emba oil. B. Z. Kanich

The flow properties of asphalts and their measurement by the penetrometer. Charles Mack. *J. Soc. Chem. Ind.* **58**, 306–10(1939).—After discussing the flow properties of asphaltic bitumens and their influence on the penetration detn., M. gives an equation, based on exptl. data, which presents depth of penetration as a function of time: $P = At^c$, where P is the depth of penetration in decimillimeters under a given load, A a const. representing the penetration at $t = 1$ sec., and c is another const. which is said to express numerically the flow properties of asphaltic bitumens as well as to evaluate viscous and plastic flow, thixotropy and elasticity. Further data show that c remains const. at all normal temps. for viscous asphalts, but varies for plastic asphalts. If the consistencies of asphaltic bitumens are expressed in terms of sec. for a given penetration with the aid of the above equation, they refer to the same shearing stress, and the consistencies of bituimens of various flow properties are comparable. H. M.

The utilization of cracked gases for deasphaltization. A. V. Druzhinina, T. F. Margolina and E. E. Pisarevskaya. *Neftyanoe Khoz.* **1938**, No. 11, 27–9; *Khim. Referat. Zhur.* **2**, No. 3, 110(1939).—Expts. with the deasphaltization of the Koschugal concentrate with the C_3H_8 and the C_3H_8-C_3H_6 fractions gave best results with C_3H_8. For C_3H_8 the optimum temp. was 25° with a 1:4 dilu. An increased temp. lowers the yield of oil, increases the yield of asphalt and sharply increases its penetration. A vapor was obtained whose yield and quality were better than when refined with H_2SO_4. To obtain the C_3H_8-C_3H_6 fraction the gases were led away from the upper plate of the stabilizing column. The gases (b. 17–27°) contained 87% of C_3H_8-C_3H_6 and 13% of C_4H_{10}-C_4H_8. This fraction gives vapors with standard properties in a yield higher than 70%. The optimum temp. was 40°, the dilu 1.6:1 with a 1 hr's. settling. The products of deasphaltization possessed a pungent odor. W. R. H.

Asphalt lute for tube joints. A. Gladkov. *Novosti Tekhniki* **1938**, No. 3, 27.—An asphalt waterproofing lute for tube joints is prepd. by heating a mixt. of natural or petroleum bitumens and finely ground asphalt at 180° until the mass is uniform and completely dehydrated. Total amt. of bitumens in the mixt. is 25–27%. The compn. should have a sp. gr. of 1.7 at 20°, tensile strength not less than 10 kg./sq. cm., elongation of the briquet not less than 15 mm., a temp. of softening at 95–105°, mobility at 130–140° and no moisture. The extd. bitumen should have a penetration of 20–40, ductility not less than 3 cm., no moisture and a softening temp. of 65–75°. B. Z. K.

Acid-resisting materials for the wood-chemical industry. K. V. Kudinov. *Lesokhim. Prom.* **6**, No. 1, 16–17(1938), *Khim. Referat. Zhur.* **2**, No. 3, 140(1939).—The metallic and the nonmetallic acid-resistant materials which can be utilized in the wood-chem. industry are reviewed. Expts. are being conducted for the utilization of acid-resistant enamel coating on app. made of Fe. The enamel is very stable not only to AcOH, but also to boiling concd. HCl. W. R. Henn

The maximum concentration of acetic acid obtained by extraction according to the method of Brüster. A. N. Brik and V. P. Sumarokov. *Lesokhim. Prom.* **6**, No. 1, 7–10(1938); *Khim. Referat. Zhur.* **2**, No. 3, 124–5(1939).—In fractional extn. with ether of AcOH from the tar-contg. liquid the first ext. (with a small amt. of solvent) contains most of the impurities (phenols, aldehydes, ketones and the higher homologues of AcOH). A comparatively pure acid is obtained in the second extn. By this method in the Ashin plant was obtained an 84% acid. The diagram H_2O–AcOH–Et_2O indicates a max. concn. of 68% the acid in the ether soln. in the presence of water. The observed higher concn. can be explained by the formation of the azeotropic mixt. ether-water. The azeotropic action increases with the decrease of the concn. of the acid in the ext. Increase the velocity of the liquids in the extractor decreases the concn. of AcOH because of the formation of ether-water emulsions and of the diln. of the acid. The use of hydrophobic solvent (pentane) is not recommended because, although it produces glacial AcOH, too large an amt. of the solvent is necessary. It is recommended to use a solvent which, according to its hydrophobic properties, is intermediate between ether and pentane. Since the coeff. of distribution of the acid between such a solvent and water is smaller (as compared with ether and water) the amt. of the solvent must be in-

creased. From the weak exts. obtained (low in water) it is possible to obtain 98-100% AcOH by distg. off the solvent. W. R. Henn

The concentration of acetic acid by means of triethylamine. P. P. Leonov. *Lesokhim. Prom.* 6, No. 2, 33 4 (1938); *Khim. Referat. Zhur.* 2, No. 3, 126(1939).—During the rectification of black acid a considerable amt. of 10-20% AcOH is obtained. The acid is mixed with triethylamine, most of the water is distd. off *in vacuo*, the unstable salt is decompd. by increasing the temp., and the acid (which has a strength of about 60%) is distd. off. The regenerated amine can be again utilized. The yield of the acid reaches 96%. Triethylamine can also be used to ext. tar water contg. 7.5% acetic acid. The yield of the 60% acid in this case is about 88%. W. R. H.

Increase of the yields of flotation oil in the rosin-extraction plant Vakhtan. S. A. Gordon. *Lesokhim. Prom.* 6, No. 1, 23(1938); *Khim. Referat. Zhur.* 2, No. 3, 125 3 (1939).—In distn. of flotation oil from rosin oil, the distn. is discontinued before all valuable terpene alcs. enter the distillate. If the distn. is permitted to continue the acids begin to go over and flotation oils are obtained which do not comply with the specifications. Since the residue is transformed into drying oils the residual alcs. are not usually utilized. It is proposed to distil still residues further and pass the vapors through a trap contg. alkali. Lab expts. showed that from 1 ton of residues it is possible 4 to obtain an addnl. 0.25 ton of the 50% flotation oil.

W. R. Henn

Production of 2-furaldehyde from hardwood. S. O. Skvortsov, G. A. Kan and D. I. El'kin. *Lesokhim. Prom.* 6, No. 1, 18 20(1938); *Khim. Referat. Zhur.* 2, No. 3, 126. Finely divided wood, e. g., sawdust, is autoclaved with 10% H_2SO_4 soln. in an amt. equal to 30–50% of the wt. of the dry substance at 4 5 atm. For each ton of the 2-furaldehyde there are obtained as by-products 0.8 ton of acetate powder, 0.1 ton of volatile substances (CH_3OH, CH_3OCH_3) and 40 tons of the hydrolyzed residue contg. 75% moisture, which can be utilized as a fuel. The cost of the furaldehyde is less than that from waste products of agriculture. W. R. Henn

Petroleum Facts and Figures. 6th ed. New York: Am. Petroleum Institute. 192 pp. $1.00. Reviewed in *Chem. & Met. Eng.* **46**, 643(1939).

Refining petroleum oil in propane solution. Claude P. McNeil (to Standard Oil Co. of Ind.). U. S. 2,177,734, Oct. 31. An arrangement of app. is described, and a 8 method of refining petroleum oil in propane soln. which involves treating the soln. with H_2SO_4 and sepg sludge, neutralizing the acid-treated oil with aq. caustic alkali soln. and sepg. the caustic wash, recovering propane mixed with acidic gases from the acid sludge and scrubbing the propane and acidic gases with the caustic wash in a closed system whereby any propane entrained in the caustic wash may be combined with the propane recovered from the sludge and whereby the unspent alky. of the caustic alkali 9 in the wash may be utilized to neutralize the acidic gases admixed with the propane.

Petrolatum mixture. Clarence M. Loane (to Standard Oil Co. of Ind.). U. S. 2,177,729, Oct. 31. A petrolatum characterized by a lower m. p. for a given penetration comprises a petrolatum characterized by relatively high m. p. for a given penetration and 1 to 10% of an isobutylene polymer resin having a mol. wt. of about 1500 to 8000.

Breaking natural petroleum emulsions. Charles M. Blair, Jr. (to Petrolite Corp., Ltd.). U. S. 2,171,328, Aug. 29. A process for breaking oil-field emulsions of the water-in-oil type involves subjecting the emulsion to the action of a demulsifying agent, such as may be formed from castor oil, glycerol, maleic anhydride and methylethanolamine or the like, comprising a sol. polymeric subresinous product having a mol. wt. of less than 100,000. Cf. *C. A.* **33**, 8978[2].

Resolving petroleum emulsions of the water-in-oil type such as "roily oil." Melvin DeGroote, Bernhard Keiser and Charles M. Blair, Jr. (to Petrolite Corp., Ltd.). U. S. 2,176,702, Oct. 17. A demulsifying agent is used derived by reaction, under substantially anhyd. conditions between a blown oil and a nonaryl hydroxyamine having at least one amino H atom, within the molal ratio of 1:1 and 1:3, at a temp. above the b. p. of water and below the point of decompn., the reaction being conducted in a manner to yield a substantial quantity of basic material in which the blown oil fatty acid radical is attached to the basic N atom through a C chain, with the added proviso that the ratio of the acid radical to amino N atom shall be at least 1.1 and not more than 2:1; the basic material being further characterized by absence of amide and polyamino radicals. E. g., blown castor oil may be treated with diethanolamine or ethanolamine. U. S. 2,176,703 relates to the like use of a demulsifying agent derived by an esterification reaction between phthalic anhydride or maleic acid or other polybasic carboxy acid and the hydroxylated product derived by reaction, under substantially anhyd. conditions, between a blown oil and triethanolamine or other nonaryl tertiary hydroxy amine, within the mol. ratio of 1:1 and 1:3 at a temp. above the b. p. of water and below the point of decompn.; 5 the last mentioned reaction being conducted in a manner to yield a substantial quantity of basic material in which the blown oil fatty acid radical is attached to the basic N atom chain; the first mentioned esterification reaction involving a polybasic carboxy acid and being conducted so as to react with the blown oil fatty acid radical which is a part of the same mol. contg. the basic N atom. U. S. 2,176,704 relates to the like use of a demulsifying agent comprising the products derived by esterification reaction 6 between (*a*) a polybasic carboxy acid, and (*b*) the hydroxylated product derived by reaction between a blown oil and a nonaryl hydroxylamine having at least one amino H atom, within the molal ratio of 1.1 and 1.3, at a temp. above the b. p. of water and below the point of decompn.; the last mentioned reaction being conducted in a manner to yield a substantial quantity of basic material in which the blown oil fatty acid radical is attached to the basic N atom chain; the first mentioned esterification reaction involving a polybasic carboxy acid and being conducted so 7 as to react with the blown oil fatty acid radical which is a part of the same mol. contg. the basic N atom. Cf. *C. A.* **33**, 8979[3].

Recovery of solvents such as cresylic acid or phenol used in solvent treatment of petroleum. Wheaton W. Kraft and Merle A. Zimmerman (to Lummus Co.). U. S. 2,177,183, Oct. 24. An arrangement of app. is described, and a method of recovering a solvent from a soln. of an org. material therein, the solvent being of a character to form with water an azeotropic mixt. condensable in a water layer contg. a small proportion of solvent and a solvent layer contg. a small proportion of water, which involves circulating the material of the water layer in a closed cycle by vaporizing the material and utilizing it as a stripping medium to strip solvent from the original soln., fractionating the stripped vapors of solvent and water substantially between dry solvent as residue and the azeotropic mixt. as distillate, and condensing and cooling the distillate vapors to form the solvent layer and water layer and to complete the closed cycle of the water layer. Cf. *C. A.* **33**, 8978[1], 9617[7].

Scrubbing petroleum distillation vapors for purification. Clayton M. Beamer and John Hooton (to Standard Alc. Co.). U. S. 2,176,196, Oct. 17. An arrangement of app. is described, and a process for the treatment of petroleum

hydrocarbon vapors from crude oil sources contg. S compds and used in the manuf. of products involving a hydrocarbon H_2SO_4 reaction, which involves initially scrubbing the petroleum hydrocarbon vapors contg. S compds. with an alk. soln. (such as a NaOH soln.) forming an alk. S compd. soln. and a substantially S-free petroleum hydrocarbon vapor, then treating the vapor with H_2SO_4 under conditions involving the formation of SO_2 in the vapors, scrubbing the SO_2-contg. vapors with the alk. S compd. soln. from the initial scrubbing operation and completely removing the SO_2 from the unreacted petroleum hydrocarbon vapors and forming H_2S and an alk. S compd. soln without the pptn. of free S.

Distilling and cracking petroleum oils. Charles H. Angell (to Universal Oil Products Co.). U. S. 2,176,320, Oct. 17. An arrangement of app. is described, and a conversion process which comprises topping crude petroleum to form topped crude oil and a distillate contg. the low antiknock straight-run gasoline components of the crude oil, subjecting the distillate in a heating coil to cracking conditions adequate to enhance the antiknock value of the gasoline components, introducing the resultant products into a reduced-pressure vaporizer, passing the major portion at least of the topped crude oil, without prior cracking thereof, directly from the topping step into the reduced-pressure vaporizer and therein vaporizing a substantial portion thereof, sepg. vapors from residue in the vaporizer and fractionating the vapors to sep. relatively heavy and light reflux condensates therefrom, subjecting such heavier reflux condensate, unadmixed with residual portions of the crude oil, in a second heating coil to independently controlled cracking conditions of temp. and pressure and subsequently discharging the same into the reduced-pressure vaporizer, supplying lighter reflux condensate formed by the fractionation to the first-mentioned coil for retreatment therein together with the straight-run distillate, and finally condensing the fractionated vapors.

Cracking hydrocarbon oils. Wm. B. D. Penniman (to Ellis-Foster Co.). U. S. 2,176,655, Oct. 17. An arrangement of app. is described, and a process which involves feeding liquid hydrocarbon material such as crude oil, gas oil or fuel oil and air to a passage heated to about 200-400°, refluxing vaporous products, then removing the vapors and condensing them, and treating the resultant condensate with alkali to remove a portion of its constituents such as phenols, etc.

Cracking hydrocarbon oils such as topped crude oils, etc. Joseph G. Alther (to Universal Oil Products Co.). U. S. 2,176,318, Oct. 17. An arrangement of app. is described, and a conversion process which comprises heating hydrocarbon oil in a heating coil to cracking temp. under sufficient pressure to maintain a substantial portion thereof in liquid phase and discharging the resultant vaporous and liquid product into a reaction chamber, also introducing charging oil for the process to the chamber, sepg. vapors from unvaporized oil in the chamber and separately removing the same therefrom, subjecting such withdrawn unvaporized oil, including liquid products discharged from the coil into the reaction chamber, to further vaporization in a second chamber, heating hydrocarbons removed as vapor from the reaction chamber to higher cracking temp. than the oil in the coil and introducing resultant heated products into contact with the unvaporized oil in the second chamber to assist in further vaporization, and fractionating and condensing the vapors from the second chamber. Cf. *C. A.* **34**, 2533.

Cracking hydrocarbon oils such as gas oils. Peter J. Wiezevich (name changed to Peter J. Gaylor) (to Standard Oil Development Co.). U. S. 2,176,234, Oct. 17. An arrangement of app. is described, and a method which comprises passing a stream of oil through a cracking zone and subjecting it to cracking therein, thereafter sepg. the cracked products into vapors contg. unsatd. gases and residue, fractionating the vapors in a fractionating zone to condense insufficiently-cracked constituents as reflux condensate, bringing the vapors in the fractionating zone into contact with a catalyst capable of causing the unsatd. gases to react to form higher-boiling hydrocarbons, removing vapors remaining uncondensed in the fractionating zone, further cooling the vapors to sep. the same into a desired distillate fraction and a normally gaseous fraction contg. satd. and unsatd. constituents, sepg. the gaseous fraction into a satd. component and an unsatd. component and passing the unsatd. component to the fractionating zone.

Polymerization and cracking of hydrocarbon gas-mineral oil solutions. Percy A. Maschwitz (to Pure Oil Co.) U. S. 2,177,146, Oct. 24. An arrangement of app. is described, and a method for cracking a hydrocarbon oil and for converting gaseous hydrocarbons into products of higher b. p. which involves heating the oil and gas in the same stream to a temp. sufficient to cause cracking and conversion under pressure in excess of 500 lb. per sq. in., subjecting the oil and gases to the conditions of temp. and pressure for a sufficient time to bring about the desired amt. of cracking, sepg. the reaction products into liquids and gases at substantially reaction pressure, subjecting the resulting gases in a sep. zone to suitable temp., without material reduction in pressure, for converting further quantities thereof to higher-boiling hydrocarbons, mixing the products from the last mentioned conversion with the liquids, and sepg. the normally gaseous from the liquid hydrocarbons resulting from the process. The mixed products may be treated to produce a finished gasoline.

Refining mineral oils with selective solvents. Merrell R. Fenske and Wilbert B. McCluer (to Pennsylvania Petroleum Research Corp.). U. S. 2,176,396, Oct. 17. The oil is extd. with a solvent for the more naphthenic portion, with resultant formation of a raffinate phase and an ext. phase, each of which contains selective solvent; the phases are sepd. and contact is effected between the ext. phase and an org. wash solvent substantially completely miscible with the selective solvent and at such temp. and in such amt. that there separates from the ext. phase a layer predominantly oil which is of different compn. from the oil in the ext. phase being treated, and this layer is sepd. App. and various operative details are described.

Removing sulfur from mineral-oil distillates. Everett C. Hughes (to Standard Oil Co. of Ohio). U. S. 2,177,343, Oct. 24. The liquid distillate is brought into contact with MgO in nascent form (suitably as produced from $MgCO_3$) at a temp. below the vaporizing point of the liquid but above 150° (suitably about 315° under pressure) and then washed with NaOH soln.

Treatment of hydrocarbon oils with solvents such as furfural. Wynkoop Kiersted, Jr. (to Texas Co.). U. S. 2,176,429, Oct. 17. App. is described, and a countercurrent treatment of hydrocarbon oil with a solvent to ext. from the oil undesired constituents, the method comprising passing the oil through a vertical tower provided with a plurality of sections of packing spaced vertically apart, one above the other, and contg. collecting means between succeeding sections for separately collecting ext. and raffinate phase liquids, moving a solvent through the tower countercurrently to the oil, withdrawing ext. and raffinate phase liquids accumulating in the spaced portions between succeeding sections of packing, mixing the liquids in proportions such that the ratio of extn. solvent to oil is substantially greater than that existing between the fresh solvent and oil entering the terminals of the tower, adjusting the temps. thereof, and returning the thus conditioned mixt. to the same spaced portion of the tower from which withdrawn.

Hydrocarbon oil conversion. Lincoln Clark, Jr. (to Lincoln Clark). U. S. 2,176,453, Oct. 17. An oil-conversion app. is used comprising walls of refractory material forming an elongated gas chamber and an elongated mixing passage having an inlet leading from the chamber at one end thereof, the passage extending in a direction transversely of the axis of the chamber, the length of the passage being a plurality of times its transverse mean cross sectional dimension, an enlarged reaction chamber communicating with passage, means for generating hot combustion gases within the chamber toward the end thereof opposite the first mentioned end, and means for projecting a high-velocity stream of hydrocarbon vapors through an

opening substantially smaller than the mixing passage inlet and thence in a straight path through an open portion of the chamber occupied by the combustion gases directly into the inlet, so that the projected vapor stream draws combustion gases from the gas chamber into the mixing passage and maintains a relatively low differential between the pressures in the gas chamber and reaction chamber.

Apparatus for heating hydrocarbon oils to effect conversion and distillation. Clive M. Alexander. U. S. 2,177,296, Oct. 24. Various structural details of an app. in which oil in tubes may be heated by oil or gas burners.

Solvent extraction of nonparaffinic fractions from hydrocarbon oils such as naphthas. Oldrich S. Pokorny and Geo. W. Gurd (to Standard Oil Development Co.). U. S. 2,176,746, Oct. 17. Nonparaffinic constituents are dissolved with a selective solvent such as a mixt. contg. β-phenoxyethyl alc. and triethylene glycol.

Removing volatiles from oil shale, coal, etc. Carl T. Loughrey. U. S. 2,177,665, Oct. 31. An arrangement of app. is described, and a method which involves confining a mass of the material in granular form and causing a hot fluid such as combustion gas to pass through the mass without pulsation to remove volatiles from the solids, and causing the fluid, with entrained vapors, to enter a body of liquid by creating vortices within the liquid and directing the fluid and vapors into the folds of the vortices so that they become temporarily occluded in the liquid and at least a portion of the vapors are condensed in the liquid which, initially, may be oil or water).

High-boiling oils from asphaltic materials. Mathias Pier, Walter Simon and August Eisenhut (to Standard I G Co.). U. S. 2,177,376, Oct. 24. An arrangement of app. is described, and a process for the production of high-boiling oils from materials, such as those of a German crude oil, by catalytic destructive hydrogenation with hydrogenating gases under pressure, which involves carrying out the hydrogenation under such mild conditions that no considerable formation of gasoline takes place and in the presence of a halogen or a H halide or substance splitting off H halide under the reaction conditions, the asphaltic substances subjected to the hydrogenation having been sepd. from hydrocarbon oils contg. them by treatment of the oils with aliphatic hydrocarbons of low b. p. such as liquefied C_3H_8.

Apparatus for pumping emulsions of oil and water such as those from oil wells. Antum E. Cuthrell. U. S. 2,177,517, Oct. 24. An app. used includes a reservoir for the emulsion, a chamber carrying a float arranged below the reservoir, a conduit connecting the bottom of the reservoir with said chamber, a heater in the conduit, a source of high pressure gas connected to the upper end of the chamber, a valve controlled by the float adapted to control the feed of gas to the chamber in such a way as to admit gas into the chamber when the liquid therein reaches a predetd height and to shut off the supply of gas when the liquid in the chamber drops to a predetd. level, a conduit for returning fluid from the chamber to the reservoir and an outlet for oil arranged adjacent the top of the reservoir.

Recovering liquefiable hydrocarbon constituents from distillate type wells. Jay P. Walker and Edwin V. Foran (to Eureka Process Co.). U. S. reissue 21,239, Oct. 17. A reissue of original patent No. 2,080,351 (*C. A.* **31**, 3151).

Rotary drum and screening apparatus suitable for separating shale from muds from well drilling, etc. Frederick L. Coogan and Earl O. Houx. U. S. 2,177,560, Oct. 24. Various structural, mech. and operative details.

Removing gyp scale from oil and gas wells. Albert G. Looms, Harold T. Byck and James F. Fidiam, Jr. U. S. 2,177,345, Oct. 24. A mixt. of HCl 55–65 and acetone 45–35% is introduced.

Apparatus for separating emulsified gas such as air from fuel oil or other liquids. Ralph B. Pressler (to S. F. Bowser & Co.). U. S. 2,177,330, Oct. 24. Various structural, mech. and operative details.

Catalytic condensation of normally gaseous hydrocarbons to form gasolinic liquids. Roderick D. Pinkerton and Wm. Mendius (to Sinclair Refining Co.). U. S. 2,177,579, Oct. 24. A process for the catalytic condensation of normally gaseous hydrocarbons including saturates and unsaturates to produce normally liquid hydrocarbons of gasoline boiling range, involves passing a mixt. of such hydrocarbons consisting predominantly of C_4-hydrocarbons contg. not less than about 40 mol % of ethane, propane and butanes and a substantial proportion but not more than about 25 mol % of normal butylene and isobutylene on its total content of C_4- hydrocarbons in contact with a phosphoric acid catalyst at a temp. of about 95–225° under a pressure upward of about 500 lb. per sq. in., whereby substantial alkylation is effected.

Metallurgical coke from petroleum coke. Earl W. Rice and Walter J. Buchele (two-thirds to Courtney W. Kimler, Sr., and Harry Hall). U. S. 2,177,226, Oct. 24. Petroleum coke breeze or fines are mixed with pitch derived from the by-product coke or coal industry 5–50% in a fine state and the mixt. is heated to a coking temp. in a vertical by-product coke oven until coking is completed, producing a metallurgical coke of the approx. analysis: 99.19% F. C., 0.37% ash, 0.44% volatile and 0.65% S.

Dewaxing mineral oils. Merrell R. Fenske (to Pennsylvania Petroleum Research Corp.). U. S. 2,176,623, Oct. 17. A process for the removal of normally solid wax components from liquid soln. in a mineral oil, the normally solid wax components being of a character such that the total vol. occupied by wax and oil when the wax is in soln. in the oil is greater than when the wax and oil exist as sep. phases, involves subjecting the solution of wax and oil to a sufficiently high pressure to cause the normally solid wax components to sep. as a sep. solid phase from soln. in the oil due to the high compressive stresses set up throughout the wax and oil by the applied pressure, removing at least a part of the latent heat of fusion which is liberated as the result of the solidification under these conditions of the normally solid wax components, and removing the sepd. solid wax components from the oil.

Dewaxing mineral lubricating oils. Robert E. Manley (to Texas Co.). U. S. 2,176,432, Oct. 17. An arrangement of app. is described, and a method of dewaxing wax-bearing mineral lubricating oil by continuous centrifugal sepn. wherein the wax is sepd. as a heavier phase and the oil as a lighter phase, comprising dilg. the oil, chilling the dilute mixt. to ppt. wax, passing the chilled mixt. to a centrifuge, centrifugally sepg. the charge into an oil phase and a wax phase heavier than the oil phase within the bowl of the centrifuge, disposing a film of hot furfural over the interior wall of the centrifuge bowl thereby providing a carrier liquid for the sepd. wax phase, moving the sepd. wax phase by flotation upon said film of carrier liquid to the point of discharge from the bowl, separately withdrawing the phases from the bowl, and discharging the sepd. wax from the centrifuge bowl in the presence of a further quantity of hot furfural.

Mineral lubricating oils treated to avoid corrosion. Frederick W. Sullivan, Jr. (to Standard Oil Co. of Ind.). U. S. 2,174,019, Sept. 26. A mineral lubricating oil such as one for automobile engines is used in mixt. with diethyl isoamyl thiophosphinite or other org. P compd. of one of the general formulas $R'_aP(XR'')_b$, $R'_aP(:Z)(XR'')_b$, $R'_aP(:Z)(XR'')_b(XH)_c$ and $R'_aP(XR'')_b(XH)_c$ in which R' and R'' represent alkyl, aryl, aralkyl, alkaryl or halogen-substituted alkyl, aryl and aralkyl groups; Z is O, S or Se; X also is O, S or Se; a and b are 1 or 2; c is 0 or 1; and in which $a + b + c$ is always equal to 3, said org. P compd. being added in small quantities to inhibit corrosion by said mineral lubricating oil (suitably about 10% or less of the amount of the oil). Numerous substances are listed which may be used.

Stabilizing mineral lubricating oils against decomposition by heat. Louis A. Mikeska and Eugene Lieber (to Standard Oil Development Co.). U. S. 2,174,248, Sept. 26. Stabilization is effected by the addn. of about 1% or less of diamyldiphenol disulfide or other alkyl phenol polysulfide of the general formula $4R\text{-}2OH\text{-}C_6H_3S_nC_6H_3\text{-}2OH\text{-}4R'$ in which R and R' are alkyl groups having at least 2 C atoms each and n is 2, 3 or 4.

Lubricating compositions. Paul L. Magill (to E. I. du

Pont de Nemours & Co.). U. S. 2,176,632, Oct. 17. A lubricating oil such as a "cutting oil" or high-pressure oil is given greater load capacity by admixt. with a reaction product of a dihydronaphthalene dimer and S. U. S. 2,176,633 relates to the use of a lubricating oil with a homogeneous, mono-phase liquid reaction product of dihydronaphthalene and S.

Hydrocarbon lubricating oils. John G. Butz and Leonard N. Leum (to Atlantic Refining Co.). U. S. 2,176,884, Oct. 24. In order to improve film strength, etc., a hydrocarbon oil contg. lubricating components is treated with a reagent comprising $PSCl_3$ at a temp. of from atm. temp. up to about 200°, and any resulting insol. reaction products are sepd.

Solvent extraction of hydrocarbon lubricating oils. Geo. Thayer (to Sinclair Refining Co.). U. S. 2,176,982 3, Oct. 24. A centrifugal countercurrent contacting app. is described, and a process which involves introducing a selective solvent such as phenol into the central portion of a centrifuge, introducing an addnl. selective solvent such as a light naphtha into the outer portion of the centrifuge, introducing the oil to be treated into the centrifuge at a point intermediate the points of introduction of the 2 selective solvents, subjecting the oil and solvents to the action of centrifugal force to produce an ext. and a raffinate phase, and separately withdrawing these phases.

Lubricating alloy bearings. Elmer W. Cook (to Tide Water Associated Oil Co.). U. S. 2,177,561, Oct. 24. Bearings such as those of internal-combustion engines, and which have substantially the corrosion susceptibility of Cd-Ag, Cd-Ni and Cu-Pb alloys, are lubricated with a mineral oil normally tending to corrode the bearing surfaces but which has its corrosive action inhibited by the incorporation of (suitably about 0.2% of) triphenylstibine.

Apparatus (with a motor, shaft and bearings) for testing the load-carrying ability of lubricating oils. Barrett E. Sibley (to Continental Oil Co.). U. S. 2,177,293, Oct. 24. Various structural, mech. and operative details.

Insulating oils. Leo J. Berberich (to Socony-Vacuum Oil Co.). U. S. 2,176,952, Oct. 24. A mineral oil suitable for impregnating cable and capacitor materials, etc., has a low tendency to loss of dielec. stability, given to it by the addn. of about 1 5% its wt. of diphenyl, dibenzyldisulfide, benzophenone or the like.

Solid and semisolid lubricants. Geo. L. Neely, Frank W. Kavanagh and Bruce B. Farrington (to Standard Oil Co. of Calif.). U. S. 2,176,509, Oct. 17. Lubricants which are suitable for use under high loads are formed of a hydrocarbon material such as an oil and tallow mixt. with an admixt. of about 2% or more of a solid, water-sol., oil-insol. carbohydrate such as sucrose, dextrose or dextrin dispersed in solid form.

Lubricants for use under high pressure. Gus Kaufman and Samuel R. Philson (to Texas Co.). U. S. 2,176,426, Oct. 17. A process for the prepn. of lubricants for use under high-pressure conditions involves forming a sulfurized lubricating oil by heating an oil such as a heavy mineral lubricating oil with S to about 175–190° for a sufficient time (suitably about 3 hrs.) to combine the S with the oil in a loosely bound form, and then incorporating Pb naphthenate in the sulfurized oil at a temp. of about 105–120°.

Electric indicating and recording apparatus suitable for use in pressure tests on greases. Paul McJunkin (to Texas Co.). U. S. 2,176,433, Oct. 17. Various elec. and operative details.

Graphite dispersion suitable for use with fuel for internal-combustion engines, etc. Floyd E. Bartell (to Acheson Colloids Corp.). U. S. 2,176,879, Oct. 24. A dispersion of colloidal graphite in nonflocculated form in an organophilic and substantially nonpolar water-insol. org. liquid such as a gasoline or kerosene is prepd. contg. a stabilizing agent such as lecithin or a mineral oil sulfonate which is strongly adsorbed to the graphite and remains adsorbed when in contact with the org. liquid and prevents flocculation of the graphite by lowering the interfacial tension between the graphite and the org. liquid.

Distillation of materials such as wood chips, peat or peat moss. Hilding O. V. Bergstrom and Karl N. Cederquist. U. S. 2,177,557, Oct. 24. An arrangement of app. is described, and a method of transforming woody material into alcohols, ketones, oils and salts of org. acids comprising heating the woody material together with sufficient added water (to prevent carbonization) and $Ca(OH)_2$ under a pressure higher than that of satd. steam in an autoclave to 220 360° by means of steam introduced into the same, so as to decompose substantially all of the woody material, the amount of $Ca(OH)_2$ being sufficient to react with the products formed by the pressure heating of the woody material to form Ca salts, withdrawing volatile substances from the autoclave and condensing the same, sepg. oily products from the aq. soln. of the condensate thereby obtained, recovering ales. from the soln., exposing the solid residue consisting principally of Ca salts from the autoclave in a sep. operation to dry destructive distn. at such a temp to form ketones from the Ca salts, condensing the escaping distn. gases and sepg. the oily products from the aq. soln., recovering ketones from the soln. and recovering from the distn. residue metallic oxides to be used for the treatment of fresh raw materials.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Physicochemical studies of the distribution of the degrees of polymerization in cellulose. I. The method of fractional solution of cellulose. Hans Dolmetsch and Friedrich Reinecke. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 219 27(1939).—The various methods of fractionation are described in detail with exptl. results and diagrams. Staple rayons from refined textiles are extremely low in low-mol. celluloses or sol. noncelluloses; normal viscose cellulose manufd. from ordinary raw materials, high in constituents of poor textile quality, contains much low-mol. cellulose. The chain length of the nitrocellulose fractions is detd. viscometrically. The chain-length diagrams give a good picture of the distribution of the cellulose mols. of various sizes in the fiber exaind. The degrees of polymerization of the fractions extd. with the same solvent from different celluloses are not the same, although the soly. of cellulose is a function of the chain length. Therefore, for an unknown cellulose it is necessary to det. for each diagram the degree of polymerization of the individual fractions. **II. The investigation of the distribution of the degree of polymerization of some natural and commercial celluloses.** *Ibid.* 299-307.—The degree of polymerization of crude cotton is 3000-4000, of ramie treated with NaOH 2000, of ramie treated and bleached 1000, of refined cellulose contg. over 96% α-cellulose 1200–1600, of paper cellulose contg. 85 92 α-cellulose 800–1300, of rayon fabrics contg. 85 92% α-cellulose 800–1300, of cuprammonium staple rayons 500–600, of special viscose staple rayons (Schwarza-Lanusa process) 450–800, of normal viscose staple rayons (W and B types) 250 350, of viscose foils 250 350, of nitro rayon 200 350, and of acetate rayon 250-300. Degradation below 200 results in a decompn. of the cellulose fiber. Soln. and chain-length diagrams showed that untreated cotton cellulose is composed of mols. of various sizes and that it does not contain low polymer constituents. The nitration takes place without degradation, but in soln. in ammoniacal copper soln. degradation can hardly be avoided. Alkali treatment and bleaching of cotton linters does not produce low-polymer constituents. The best raw materials for artificial textile fibers are cotton linters and wood cellulose. Chem. purity and uniformity of ordinary celluloses is not sufficient for acetylation (rayon), and nitration (gun cotton), or the manuf. of cuprammonium spinning soln.;

it is necessary to use refined cellulose for these processes. This refinement is carried out with alk. baths which dissolve to a large extent the low-polymer constituents of cellulose and the contaminants. After the extn. of the low-polymer constituents the chain-length diagram of a refined cellulose becomes similar to the characteristic diagram of cotton linters. The soln. diagram of linters differs from that of refined celluloses, in the region of high degree of polymerization, owing to a higher packing density of the cotton. The chem. changes that occur during alkali refinement are demonstrated by soln. and chain-length diagrams. The degree of polymerization of the first fraction is higher for the refined celluloses than for the original products. The soln. of cellulose by NaOH is accompanied by an expansion of the crystal lattice, which increases the reactivity and effects due to mol. size of the cellulose. This is due not merely to the effect of the base but also to an oxidizing cleavage by air, which cannot be excluded in large scale com. operations. The change in the soln. diagram and the chain-length distribution which occurs in 1 hr. in a com. alkalization is illustrated. In a process of wet alkalization with chem. ripening, cellulose is mixed with NaOH to a thick fluid pulp and the viscosity is lowered very rapidly by the addn. of oxidizing agents. When the proper degree of ripeness is reached the base is removed and alkali cellulose suitable for xanthation is immediately isolated. In this process the long mols. are decompd. and the low-mol. constituents are extd.; thus the product is more uniform in compn. The observation that the decompn. of cellulose in the viscose process takes place primarily before the xanthation and that the xanthate is highly stable against oxidative cleavage was confirmed by chain-length diagrams for normally ripened alkali cellulose, viscose staple rayon made therefrom, and special staple rayon Schwarza. The distribution of the chain length is shown to be due chiefly to the preripening and not to the afterripening or the spinning process. After the removal of the alkali the degree of polymerization of the first fraction is nearly const. during the viscose process. An alk. process was developed which yields a product of α-cellulose content 98.8%, Cu viscosity 175, mean degree of polymerization of 850 (as nitrate) and pentosan content of about 3%. It is more like linters than is ordinary wood cellulose. Soln. diagrams of the nitrates of fiber grades of staple rayon show great variations of the mean degree of polymerization and alkali soly. at initial stages but parallel behavior at the end of the curve; however, the chain length distribution curves differ greatly from the corresponding soln. curves, owing to differences in the degree of crystn. or packing density. Cellulose products of variable tear resistance, nearly identical titer and equal mean degree of polymerization yielded practically identical soln. and chain-length diagrams and alkali soly. There was a remarkable agreement between wet resistance and the orientation angle detd. by x-ray methods; hence the resistance to tearing of a fiber spun from normal viscose is related to the parallel structure of the crystallites in the fiber. The special staple rayon Lanusa (manufd. from linters) has a mean degree of polymerization of 700 (detd. as nitrate), high wet resistance and low alkali soly. Leopold Scheflan

Enzymic decomposition of polymeric carbohydrates. III Behavior of linden wood toward ethylene diamine-copper oxide solution and the enzymic degradation of the main fractions. Theodor Ploetz. *Ber.* **72B**, 1885-9 (1939); cf. *C. A.* **34**, 1039⁹.—Treatment of the finely ground wood (C 49.59, H 6.37, MeO 6.51%) of *Tilia tomentosa*, after exhaustion with benzene-alc., with the Hilpert reagent (I) (*C. A.* **33**, 5178⁹) left 61% undissolved, and from the soln. acids pptd. 12.7%. The insol. residue (C 49.62, H 6.55, MeO 7.20%) hardly differed in compn., except in MeO content, from the original wood, but a better idea of the change it had undergone was given by the detn. of its chief constituents: Cross-Bevan cellulose (pentose-free) 60.5, pentoses 8.67, lignin (detd. as Klason lignin) 20.55%, as against 45.5, 26.1 and 18.0% resp., for the original wood. Hence 18.9% of the cellulose, 79.7% of the pentoses and 30.5% of the lignin had dissolved in I. The soln. of 30% of the lignin is to be considered as a fractionation, for the lignin (C 61.32, H 6.04, MeO 20.91%) obtained from the residue insol. in I differs from that (C 64.60, H 5.50, MeO 19.86%) obtained from the original wood. The fraction pptd. from the soln. in I by acids was a yellowish powder with C 45.98, H 5.91, MeO 7.23, pentoses 49.6, lignin 26.14% (the lignin contained C 61.40, H 5.25, MeO 15.64%). This fraction therefore consists of lignin and an MeO-contg. substance which does not go over into Klason lignin. Neither the fraction insol. in I nor that pptd. by acids contains N. The enzymic degradations were effected with various purified prepns. from the digestive juice of the Weinberg snail (*Helix pomatia*), which contain cellulase, lichenase and cellobiase. The original wood is quite resistant to enzymic attack. A not very active enzymic prepn. which degraded cuprophan only 23% in 6 days dissolved only 3.8% of the wood in the same length of time, and the most active prepns., which completely dissolved cuprophan in 2-3 days, degraded the wood only 14% in 8 days. Of the sugar going into soln., 35% consisted of pentoses. This proportion remained quite const. on repeated treatment with different enzyme prepns., indicating that both classes of carbohydrates, pentoses and hexoses, from the beginning dissolve in about the same proportions in which they are present in the wood. The residue insol. in I showed no increased sensitivity to enzymic attack. Even after long treatment and with repeated renewal of the enzyme, only 18.6% could be brought into soln. The sugar detns. and the loss in wt. gave entirely concordant results on the extent of degradation; 42.5% of the sugar consisted of pentoses. On the other hand, the fraction pptd. from I by acids was relatively easily degraded, 51.4% in 2 stages; 70% of the dissolved sugar consisted of pentoses. The degraded solns still contained MeO. The residue now had C 51.77, H 6.36, MeO 9.07%. At this stage the hitherto smooth degradation suddenly became very halting with even the most active enzymic prepns., but after 13 days a further 9.8% degradation was obtained; the dissolved sugar contained 92% pentoses. Although these degradations, which in the last stage are very time-consuming, have not been completed they justify the hope that it may be possible, under the mild conditions of enzymic degradation (pH 4-7 at 37°), to isolate lignin-like substances from the native material. The increase in C content of the residue after 51.4% degradation points distinctly to the presence of lignin-like components of high C content C. A. R.

Unesterified primary hydroxyls in acetone-soluble cellulose acetate. F. B. Cramer and C. B. Purves. *J. Am. Chem. Soc.* **61**, 3458-62 (1939).—*p*-$MeC_6H_4SO_2Cl$ in C_5H_5N at 20° rapidly esterified about 1/3 of the free HO groups in com., Me_2CO-sol. cellulose acetate (I); the remainder reacted much more slowly. No removal, and probably no wandering, of Ac groups occurred. NaI in Me_2CO at 100°, or HCl in C_5H_5N at 85°, smoothly substituted I or Cl atoms for *p*-$MeC_6H_4SO_2$ residues derived from primary, as opposed to secondary, HO groups. Analyses of the halogenated mixed cellulose esters indicated that at least 1/3 of the free HO groups in I were in the primary (sixth) positions of the anhydroglucose units. The esterification was interrupted at the end of the initial, rapid reaction and the groups introduced were replaceable to the extent of 85-90% by I; *p*-$MeC_6H_4SO_2Cl$ had therefore reacted 10 or 12 times as rapidly with the free primary as with the free secondary HO groups (2nd and 3rd positions). All the above reactions proceeded almost quantitatively and without appreciable degradation of the cellulose as measured by viscosity methods. The position of I in a 6-iodocellulose acetate was confirmed by the reduction to a degraded 1-free desoxy acetate. This gave methylfurfural on distn. with mineral acid and glucomethylose (isorhamnose) after complete hydrolysis. C. J. W.

Unesterified secondary hydroxyls in acetone-soluble cellulose acetate. F. B. Cramer, R. C. Hockett and C. B. Purves. *J. Am. Chem. Soc.* **61**, 3463-4 (1939).—A com. Me_2CO-sol. cellulose acetate had an av. of 0.35-0.45 mole of unesterified HO distributed between the 2nd and 3rd

positions of the anhydroglucose units. The unsubstituted —CHOH.CHOH— or glycol groupings it contained were estd., by means of $Pb(OAc)_4$, to occur not more frequently than once in 100 glucose residues. A significantly greater frequency of 1 in 20–30 was calcd. by assuming a purely random distribution of HO between the 2 positions. C. J. West

Ethers and esters of cellulose and their commercial applications with particular reference to the textile industry. H. Rath. *Klepzig's Textil-Z.* **42**, 491–4(1939).—A discussion of the constitution soly., prepn. and application of cellulose esters and ethers. Leopold Scheflan

A simple and rapid method for the quantitative separation of artificial fibers [prepared] from hydrated cellulose and fibers from natural cellulose. Karl Schwertassek. *Angew. Chem.* **52**, 700–1; *Kunstseide u. Zellwolle* **21**, 422–6(1939).— The method consists in treating the fibers with cold 10% NaOH soln. contg. some wetting agent. The soaked fiber gels are pressed by rollers on a fine screen where the artificial fibers break down and pass through owing to their lower mech. resistance and the natural fibers remain as their resistance even in the soaked condition is fairly high. Acetylcellulose fibers must be removed prior to the test by soln. in acetone. Wool loses considerable wt. and the method is not applicable to it in the present state. Karl Kammermeyer

Machines for the production of staple rayon and rayon in the laboratory. Herbert Fischer. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 309–10(1939).— An illustrated discussion. Leopold Scheflan

Industrialization of [Cuban] bamboo. Carlos Rodriguez Casals. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* **1938**, 236–9.— The cellulose of this plant can be used for making rayon and a general line of high-quality papers. O. W. Willcox

Rapid determination of moisture in wood pulp. L. M. Perelygin. *Lesnaya Industriya* **1939**, No. 5, 62–4.—Moisture in wood pulp can be detd. rapidly by drying in an air stream at temps. up to 200°. The error in most cases does not exceed 0.5% for air-dry pulp and 1.5% for moist pulp and the times required for the detns. were 15 and 20 min., resp. B. Z. Kamich

Sweden's first fan drying machine for ground pulp. Sven Wellmar. *Svensk Papperstidn.* **42**, 539–40(1939).— App. is described. Fan drying uses only 40% as much steam as the old method. Personnel and financial savings are given in detail. Wilhelm Segerblom

Technical evolution of wood-grinder construction. Robert Stehr. *Zellstoff u. Papier* **19**, 605–8(1939).—Various recent types of mech. pulp-grinding equipment are described. S. I. Aronovsky

Degree of efficiency of sulfite acid towers. Hugo Nihlén. *Svensk Papperstidn.* **42**, 491(1939); cf. *C. A.* **33**, 8988⁸.— N. points out that Sylwan's efficiency formula is correct only when no SO_3 is formed in the tower. Wilhelm Segerblom

Investigations of black liquor. Hilding Bergström and Kari G. Trobeck. *Svensk Papperstidn.* **42**, 554–7(1939).— New methods are reported for the detn. of H_2S, mercaptans and sulfides in the vapors and gases from black liquor and for the detn. of its sulfide content. The gases from the evapd. black liquor are cooled and then passed successively through a 10% $CdCl_2$ soln. contg. 1% HCl to absorb the H_2S, through a 5% $Hg(CN)_2$ soln. to absorb the mercaptans, and lastly through a 5% $HgCl_2$ soln. to absorb the org. sulfides. From the ppts. formed the amts. of the impurities are detd. Diagram of app. and details of procedure are given. To det. the sulfide content of black liquor, the liquor is treated with 10% NH_4Cl soln., and the mixt. boiled in an oxygen-free atm. of N, the gases being detd. as before. The change in the sulfide content in black liquor has been shown to be due to oxidation, and that it increases with rising temp. The sulfide S is oxidized first. Details are given. W. S.

Macromolecular compounds. No. 221. The degree of polymerization of various types of cellulose. H. Staudinger and F. Reinecke. *Holz Roh u. Werkstoff* **2**, 321–323 (1939); cf. *C. A.* **33**, 7095³.—The tearing and bursting strength increase with degree of polymerization, becoming nearly const. at about 1000. The viscosity of a 1% soln. in Schweitzer's reagent continues to increase beyond 1700. Data are given on the degree of polymerization and viscosity of pulps from different sources and by different processes, as well as of different artificial textile fibers. Cellulose is the one important constituent of wood to be converted to textiles, as other constituents tend to dissolve in the alk. treatment. R. H. Baechler

Paper and color. Archim Skjöldebrand. *Svensk Papperstidn.* **42**, 462–7(1939).—The properties required for satisfactory newsprint paper are described in detail with special reference to its handling and use. W. S.

Wool, felts and paper drying. F. W. Holl. *Zellstoff u. Papier* **19**, 612–15(1939).—The chem., mech. and temp. effects of paper drying on wet and drier felts are discussed in detail. Wool is the best material so far available for the production of these felts. S. I. Aronovsky

Felt drying. Johannes Bartsch. *Zellstoff u. Papier* **19**, 616–18(1939).—The drying of paper machine felts, both on the machine and after removal from the machine and washing, is described, and the effects of these procedures on felt life are discussed. S. I. Aronovsky

Beating parchment and parchment substitutes with regard to the rapid development of the required paper properties. R. Muller. *Zellstoff u. Papier* **19**, 609–12(1939).— The development of the "turnstile" mill for pulp beating furnishes another unit for the proper prepn. of paper stock. This large-surface beating machine is very acceptable to the industry at present owing to its high output at lower power consumption and with less fiber destruction, as well as to lowering the blistering point and increasing the strength of the strongly beaten pulp. S. I. Aronovsky

Analysis of [cellulose derivs.] for traces of metallic impurities (Owens, Reinhardt) **7**. [Sewage] digestion studies on paper pulp (Hill) **14**. Tubing from cellulose derivs. (U. S. pat. 2,176,925) **12**.

Cellulose organic acid esters. Carl J. Malm (to Eastman Kodak Co.). U. S. 2,176,088, Oct. 17. A process of making high viscosity esters of cellulose involves presoaking cellulose such as cotton linters in about 5 times its quantity of a lower fatty acid bath (such as mixed HOAc and propionic acid) contg. HOAc at a temp. of about 13° and subsequently esterifying the presoaked cellulose by adding a refrigerated esterifying liquid contg. a lower fatty acid anhydride such as Ac_2O about 3.36 parts for each part of cellulose treated together with an esterification catalyst such as H_2SO_4 (this liquid having a temp. of between −18° and about 0° and the temp. of the esterification mass being kept below 32°). Cf. *C. A.* **34**, 623¹.

Rendering cellulose ethers quickly soluble. Hermann Neuroth (to Kalle & Co. A.-G.). U. S. 2,176,678, Oct. 17. A fibrous sol. cellulose ether such as cellulose methyl ether is rendered quickly sol. by introducing the fibers between parallel plates spaced a short distance apart and having corrugated inner surfaces, and rotating the plates relative to each other until the fibers are arranged into twisted bundles.

Use of cellulose ethers and viscose in forming films or threads, etc. Leon Lilienfeld. U. S. 2,176,085, Oct. 17. A material suitable for films, etc., is prepd. by a process in which an alkali-sol. cellulose ether and viscose are brought together in such proportions that the CS_2 in the viscose is less than 20% of the sum of the wt. of the cellulose contained in the viscose plus the wt. of the cellulose ether used. Such a mixt. gives products of good strength.

Esters such as cellulose acetate. Carl J. Malm (to Eastman Kodak Co.). U. S. 2,177,667, Oct. 31. In the production of an ester, as by acylating cellulose followed by partial hydrolysis, pptn., washing with water, and drying, uniform viscosity of the product is maintained by maintaining the effective hardness of the water employed for washing uniform over an extended series of batches.

Cellulose acetate from wood. Lionel E. Goff (to Cellulose Research Corp.). U. S. 2,176,850, Oct. 17. An ar-

rangement of app. is described, and a process of producing cellulose acetate from wood by treating wood with a sulfite delignifying soln. to produce pulp, washing the pulp with water at elevated temp., defibering and screening the pulp to remove neps and fiber bundles and to provide a max. exposed surface of ligneous material, chlorinating the pulp with an amt. of Cl expressed in lb. equal to 16–18% of its bleach value, removing the chlorinated compds. by treatment with a dil. soln. of NaOH at a temp. in excess of 60°, bleaching the chlorinated pulp with a hypochlorite soln. of from 1–6% concn., with a pH above 8, at 25°–35°, treating the bleached pulp in a nonmercerizing soln. of NaOH at a temp. in excess of 60°, repeating the bleaching treatment with hypochlorite, mercerizing the bleached pulp in a 12–15% soln. of NaOH at 25°–35°, washing the mercerized pulp in less than 30 min. with water until neutral, treating the mercerized pulp with HOAc at a temp. in the range from 50° to boiling, displacing the treating acid with glacial HOAc, thereafter treating the cellulose with Ac_2O in the presence of a H_2SO_4 catalyst.

Nonfibrous films such as those of cellulose acetate or polyvinyl alcohol. Emmette F. Izard (to E. I. du Pont de Nemours & Co.). U. S. 2,176,903, Oct. 24. In casting films, the stripping character of the film produced, when cast upon a surface such as a casting wheel, is improved by including in the casting soln. about 2% or less of stearylamine, octadecylamine or other normally solid primary alkyl amine of a high mol. wt. hydrocarbon or a salt of such an amine, which, in the quantity used, does not materially affect the transparency of the resultant film.

Products such as threads from cellulose xanthate. Josef Lilienfeld. U. S. 2,176,799, Oct. 17. Products which have good luster, strength and extensibility are formed by adding to a xanthate of a cellulose material an alkyl ester of an O-contg. inorg. acid such as Et_2SO_4 and treating a soln. of the resulting product, shaped as desired, e. g., in the form of threads, with a coagulating agent, and plasticizing the freshly coagulated product. Several examples with details are given.

Cellulose films suitable for use as wrapping tissue. Henry S. Rothrock (to E. I. du Pont de Nemours & Co.). U. S. 2,170,839, Aug. 29. A water-sensitive film suitable for use as a wrapping tissue is formed from an aq. alk. cellulose soln. and contains, as a deformation-restricting agent, a softening agent comprising bis(ethoxyethyl) succinate or other org. ester having a hygroscopicity of from 1 to 80, a b. p. of at least 135° at a pressure of 12 mm. Hg, and a soly. of at least 1% in water at 20°, the ester being present in sufficient amt. to restrict the deformation of the film to a max. of 3.0. U. S. 2,170,840 relates to the like use of propylene glycol dilevulinate or other ester of a keto acid having similar properties and effect.

Fiber-forming polyamides. Wesley R. Peterson (to E. I. du Pont de Nemours & Co.). U. S. 2,174,527, Oct. 3. A process for making fiber-forming substantially viscosity stable polyamides comprises heating a mixt. of polyamide-forming reactants consisting essentially of a diamine of the formula $H_2NCH_2RCH_2NH_2$ and a compd. of the class consisting of dicarboxylic acids of the formula $HOOCCH_2R'CH_2COOH$ and amide-forming derivs. of such acids in the presence of a viscosity stabilizing agent of the class consisting of monofunctional amide-forming compds. and their derivs. capable of functioning as such under the condition of the reaction, said monofunctional compds. being selected from monofunctional carboxylic acids or monofunctional nitrogenous bases, R and R′ in said formulas being bivalent hydrocarbon radicals free from aliphatic unsaturation and R having a chain length of at least 2 C atoms. The monofunctional compds. may be monobasic org. acids and monofunctional nitrogenous bases which contain at least one H atom attached to the N atom. The nitrogenous bases include ammonia, monoamines and compds. capable of yielding NH_3 or monoamines under the conditions of the reaction. The term polyamide-forming reactant is used to designate a bifunctional compd. which yields a polyamide when heated alone or in admixt. with a complementary polyamide-forming reactant. It includes polymerizable amino acids or amide-forming derivs. thereof (i. e., an ester, acid halide, amide, or anhydride), diamines, dicarboxylic acids, and amide-forming derivs. of dibasic carboxylic acids. In contrast to the polyamide-forming reactants, the monofunctional amide-forming reactants are not capable of yielding polymers. Various examples with details of procedure are given.

Spinning funnel for rayon. Cornelis G. Jansen (to American Enka Corp.). U. S. 2,177,322, Oct. 24. A spinning funnel is used having a hard thread-guiding surface of material such as glass etched (as by HF) adjacent its outlet end to provide a myriad of minute depressed portions capable of effecting the entrapment of globules of liquid to form an antifriction surface for the thread during operation of the app.

Gear-wheel spinning pump. Otto Bochmann (to Barmer Maschinenfabrik A.-G.). U. S. 2,176,388, Oct. 17. A pump suitable for use in rayon manuf. comprises a casing and rotatable gear wheels of a steel alloy contg. 0.7–1.1% C and 12–16% Cr and having a hardness of at least 60 Rockwell C.

Treating colored rayon to improve fastness of color. James G. McNally and Joseph B. Dickey (to Eastman Kodak Co.). U. S. 2,176,506, Oct. 17. Colored materials such as those of cellulose acetate colored with various dyes are treated with an aq. soln. of melamine, which serves to give improved fastness of color.

Loose-belt drive for papermaking machines. Bernard A. Malkin (to Dominion Engineering Works Ltd.). U. S. 2,176,431, Oct. 17. Various structural, mech. and operative details.

Coating paper. Laurence W. Porter (to S. D. Warren Co.). U. S. 2,177,580, Oct. 24. App. is described, and a method of coating paper, which comprises applying to a surface of a moving web of paper an excess of an aq. coating compn. comprising carbohydrate adhesive and pigment, and removing excess coating compn., the viscosity and solids content of the coating compn. being balanced against the absorptivity of the paper and the wt. of coating so that the coating assumes a plastic and wet but nonflowing condition; then superimposing upon the wet and plastic but nonflowing coating a second coating layer of aq. coating compn. comprising protein adhesive and pigment, the second coating layer not freely mingling with the first coating but the two layers bonding together at a more or less plane interface; smoothing the resulting composite coating; and drying the resulting coated product. Pigments such as blanc fixe and satin white may be used with adhesives such as clay and casein.

24—EXPLOSIVES AND EXPLOSIONS

C. G. STORM

The ammonium explosives. P. Radevich. *Tekhnika i Vooruzhenie* **1938**, No. 7, 86–94; *Khim. Referat. Zhur.* **2**, No. 2, 127 (1939).—Ammonites are the main types of explosives used in the industrial practice in U. S. S. R. They are mech. mixts. of NH_4NO_3 with nitro derivs. (dinitronaphthalene, etc.) or with combustible materials, such as coal or sawdust. The production technology of the ammonites consists in drying and grinding followed by mech. mixing of the components. In comparison with other explosives the storage of the ammonites is simple, owing to the low sensitivity to shocks, friction and climatic conditions. Hygroscopicity and deterioration are the main disadvantages. Methods for combating these disadvantages are given. Properties of the most commonly used ammonites are described. W. R. Henn

The harmlessness of constant-boiling 72% perchloric

acid. Walter Dietz. *Angew. Chem.* **52**, 616–18(1939).— Expts. are described which show that 72% $HClO_4$ (const.-boiling) is entirely harmless in the absence of combustible substances. Expts. with mixts. of $HClO_4$ vapor and H resulted in explosions at 400 5°. The presence of steel turnings in the vapor space lowered the temp. of explosion to 215°. The explosions experienced when $HClO_4$ is used in steel analysis (detn. of Cr) are apparently due to the formation of mixts. of $HClO_4$ vapor and H which are exploded by the catalytic action of undetd compd. steel particles. The formation of the explosive gas mixts. can be prevented by the addn. of a little water during the soln. of the steel. All steels dissolve easily in aq. $HClO_4$ when boiling temps. of 150 60° are reached and dangerous amts. of $HClO_4$ vapor are not evolved at this temp. 11 references. Karl Kammermeyer

Cold flames. II. J. M. Stevels. *Chem. Weekblad* **36**, 654–7(1939); cf. *C. A.* **33**, 9647[1].—A review of recent developments in cold-flame technique. 18 references. **III.** *Ibid.* 657–63.—A review of the importance of cold-flame theories in the investigation of chem. union. 32 references. O. W. Willcox

Modern detonators. Wilfrid Taylor. *Chemistry & Industry* **1939**, 1065–9. E. H.

Explosives suitable for priming. Edward B. W. Kerone and Clayton C. Carroll (to Western Cartridge Co.). U. S. 2,177,657, Oct. 31. A salt of a nitrosoresorcinol, such as a basic Pb nitrosoresorcinate, is used (suitably with Hg fulminate or Pb azide, $Ba(N_3)_2$, etc.).

Track torpedo containing a detonable explosive. Louie A. Sherman (to Safetee Torpedo Corp.). U. S. 2,176,362, Oct. 17. Various structural details.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The semiquinone radicals of methylene blue and related dyestuffs. S. Granick, L. Michaelis and M. P. Schubert. *Science* **90**, 422–3(1939).— It has been shown that thionine (Lauth's violet) when reduced in strongly acid soln. contains the semiquinone (free radical) which is yellow and exhibits a series of distinct absorption bands in the blue part of the spectrum similar to the bands of the triphenylmethyl radical. This is presented as further proof of the theory of compulsory univalent oxidation (M. and Smythe, *C. A.* **33**, 3831[2]) which has never been shown to apply for thiazine or oxazine dyes. Methylene blue acts similarly to thionine in a slightly higher acid concn and shows a similar absorption spectrum for the semiquinone radical. These dyestuffs are considered to fit very well into this theory since any bivalent oxidation-reduction system must be capable of forming a semiquinone radical to some extent in order to behave as a reversible system. It is further stated that any org. dyestuff can act as a catalyst for slow oxidation when this radical is formed. Recently, it was shown (*C. A.* **33**, 7750[1]) that the first oxidation product of diaminodurene (1,4-diamino-2,3,5,6-tetramethylbenzene) was a free radical while the *N*-methylated compd. did not form this radical. The diaminodurene increases respiration of erythrocytes to about the same extent as methylene blue where the *N*-methylated compd. has no catalytic effect. R. F. D.

The preparation of printing dyes. B. V. Ponomarenko. *Legkaya Prom.* **1938**, No. 7–8, 94–108; *Khim. Referat. Zhur.* **2**, No. 3, 116–17(1939).—The production of printing dyes was investigated in the lab. and on production scale from the *hygienic standpoint*. The prepn. of pastes not with oil and with acetol, and the prepn. of $Al(NO_3)_3$ are harmless. Some processes are harmful owing to the gases and vapors evolved. The harmful gases which should be removed are SO_2, Cl_2, NO_2, vapors of AcOH, CH_2O, PhOH and HCOOH. The heating of the indanthrene printing dyes is injurious because of the evolution of HCOOH. The diazo solns. produce injurious oxides of N. W. R. Henn

The migration of substantive dyes in artificial textile fibers in comparison to the behavior of dye solutions and the gel structure of textile fibers. W. Weltzien and H. Froitzheim. *Monatsh. Seide Kunstseide Zellwolle* **44**, 185–90, 238, 240, 242, 244–5, 269–75, 314–18, 320, 322(1939).—From expts. described in detail are drawn the following conclusions: (1) The diffusion of substantive dyes in soln. and their penetration in the fiber differ fundamentally. In soln. the addn. of electrolyte causes a lowering of the diffusion while in the fiber it hastens the penetration of the dye. The larger, more aggregated dye particles penetrate faster into the fiber than the smaller particles; this is explained by an increase of the adsorption velocity at the inner surface of the fiber with increased electrolyte addn. In the pretreatment of the fiber with alkalies similar processes take place. (2) The alk. treatment shrinks the fiber, causing a disorientation of the micellar arrangement, and dissolves small amts. of the fiber, rendering the inner surface generally more accessible. (3) As the treatment with alkalies increases greatly the absorption velocity of the dye, the particular properties characteristic for Brilliant Benzo Blue 6B do not appear in case of viscose rayon. The pretreatment with NaOH increases the dye-absorption power of different rayons to various degrees; however, the final result after complete pretreatment is approx. the same. (4) The influence of various textile assistants, with the exception of Peregal O, is explained by a difference in the penetration of the dye. This is in partial agreement with the strong capillary activity of these substances. The diffusion velocity is decreased slightly. Therefore, the stabilizing effect of the textile assistant cannot be explained by any essential influence on the degree of dispersion. (5) From the results obtained conclusions are drawn concerning the gel structure of Cu rayon and other textiles. 67 pictures and 26 references. Leopold Scheflan

New experiences with acetate rayon dyes. Erich Herrmann. *Monatsh. Seide Kunstseide Zellwolle* **44**, 231–6(1939).—A discussion of dyeing at high temp., production of fastness to light in delustered dyed acetate rayon, resistance of celliton and celliton fast dyes against various aftertreatments following the dyeing of mixed fabrics contg. viscose rayon, the dyeing of mixed fabrics contg wool and acetate rayon and the advantages of the use of the water-sol. developer ONL for cellitazol dyeings over the older developer ON. Numerous dyes suitable for the various treatments and sp. dyeing directions are given. Leopold Scheflan

The application of naphthol dyes to cotton and other textiles. II. Joseph Lindsay, Jr. *Cotton* (Atlanta) **103**, 67–8, 112(Dec., 1939); *C. A.* **34**, 629[7].—This instalment covers the chem. constitution of the naphthols, fast color salts, the pH of the developing bath, substantivity of naphthols, printing with naphthols, etc. W. H. Boynton

Fast Indanthrene Red for the dyeing of clothing. Richard Alt. *Deut. Färber-Ztg.* **75**, 345–6(1939).—Practical directions are given for dyeing clothing by means of dyes of the Naphthol AS type as well as other dyes. L. S.

How dyes are broken down. E. Dutoit. *Teintex* **4**, 608–11(1939).—A discussion of methods used to remove the dye from dyed fabrics so that they can be redyed in some other shade. Certain direct dyes, basic dyes and acid dyes come off in a slightly alk. bath (ammonia, soap, Na_2CO_3 for vegetable fibers, and ammonia, Na_2SO_4, for animal fibers) when they are warmed slightly and agitated in these solns. After a rinsing in a slightly alk. bath the material is ready for redyeing. Saverio Zuffanti

Reserve and two-color effects on artificial textile fiber crepe fabrics. Veseley. *Monatsh. Seide Kunstseide Zellwolle* **44**, 265–9(1939).—A discussion of proper dyeing

operations. In a textile mixt. viscose can be dyed readily without dyeing acetate rayon; however, all wooden vats must be freed completely from acetate dyes and mistakes in the pretreatment of the acetate fiber during bleaching and delustering may cause the acetate fiber to absorb substantive dyes. Dirty acetate rayon can be cleaned by soaping at 30–40°, by the hyposulfite soln. or by a dil. soln. of AcOH. Spots of special acetate dyes are best removed with activated charcoal. Leopold Scheflan

Light-fast, commercially used color tones from Sirius and Sirius Light dyes. H. Hansen. *Klepzig's Textil-Z.* **42**, 520–22, 524(1939); cf. *C. A.* **33**, 7115⁵.—A detailed description of the production of various color tones. Dyes are listed suitable for dyeing of fabrics contg. acetate rayon, mixed yarns of cotton and viscose rayon, viscose rayons of different affinities, and delustered rayons. Cl-resistant dyes and Sirius and Sirius Light dyes of good leveling properties are tabulated. Leopold Scheflan

Improving unsuccessful dyeings. Willi Festerling. *Deut. Farber-Ztg.* **75**, 371–2(1939).—A discussion of com. industrial practices. Leopold Scheflan

The practical application of dyes for mixed fabrics in the dyeing of clothing. G. Krüger. *Klepzig's Textil-Z.* 42, 439–41(1939). The goods should be tested for the presence of acetate rayon. Procedures for using direct semiwool dyes, single-bath diazotization, semiwool metachrome processes and black dyeing with Autazolchrome Black R are discussed. Leopold Scheflan

Dyeing brown uniforms gray. Hermann Zill. *Deut. Farber-Ztg.* **75**, 489(1939).—The brown color should be removed with soln. of Dekrolin and HCOOH with Modinal or a similar textile assistant as protecting agent. In the case of certain vat dyeings a yellow color remains after this treatment; this color is then changed into gray-green by using an indigo MLB paste. Only wooden vessels should be used for these treatments as well as for rinsing. All Dekrolin must be removed thoroughly to ensure the complete destruction of the brown color. The first rinsing bath should contain H_2O_2 or other O-forming compd., and the second bath should be made alk. with NH_3. The residual H_2S of the Dekrolin is thus oxidized to H_2SO_4 and the color tone becomes clearer. The redyeing is best done with fast alizarin or anthralan dyes in the presence of Glauber's salt and AcOH (no HCOOH should be used). The leveling is facilitated by the use of $AcONH_4$. The addn. of Modinal to the dyeing bath renders the goods softer and ensures thorough dyeing of the thick seams. L. S.

Dyeing cellulose fibers with acid wool dyes in the presence of synthetic resins. Theodor Crebert. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 146–58, 182–7, 227–31(1939).—Rayon textiles contg. artificial resins bearing NH_2 groups can, like wool, absorb acid dyes. The condensation of glutamic acid with glycerol produces very viscous brown oils which, by the catalytic action of HCl, can be further condensed, with chain formation. The products are brown resins which, because of soly. in water, are useless for dyeing purposes. An insol. product was formed by incorporation of glutamic acid in the phthalic acid glycerol complex, but its ease of sapon. renders it not very suitable as an addn. product to viscose. Bakelite obtained by alk. condensation contains alc. OH groups which can be esterified with dicarboxylic acids and particularly with glutamic acid. The esterification never takes place on both COOH groups and, therefore, it is possible to esterify the Bakelite dicarboxylic acid semiester further. Resins thus produced are neutral, light in color and alkali-sol.; they are most useful for treating the textile fiber so that it will absorb acid wool dyes. Dicarboxylic acids can be introduced into an acid-condensed Bakelite which contains no alc. OH groups by using the acid anhydrides, e. g., phthalic anhydride. In the product thus obtained, one COOH group can be esterified further with glycerol and condensed with free OH groups of the glycerol-glutamic acid compd. Such resins do not exhibit the desirable properties shown by the product from alkali-condensed Bakelite. The alc. OH groups of alkali-condensed Bakelite can be easily made to react with one NH_2 group of a diamino compd. without binding the second NH_2 group. These condensation products are very efficient and upon addn. to viscose increase greatly the dye-absorbing power. The no. and type of linkage of the free NH_2 groups increases or decreases the dye-absorption power of the fiber. If ethylenediamine is made a constituent of the resin a product is obtained which increases the dye-absorption power toward acid wool dyes exceptionally well. Leopold Scheflan

Spun-rayon dyeing and finishing. I. Staple and yarn dyeing. T. R. Brockleman. *Textile Bull.* **57**, No. 3, 8, 10(1939).—Dyeing operations for the cut staple and spun rayon yarns are discussed in detail and typical direct color formulas are given. Leopold Scheflan

German flax—German linen. Erich Schindler. *Klepzig's Textil-Z.* **42**, 287–8, 319–21, 417–18, 457–8(1939).—A survey of the industry. Leopold Scheflan

Comparative studies on the determination of the quality of fibers in the flax stem. Herbert Ulbricht. *Klepzig's Textil-Z.* **42**, 447(1939).—The detn. of the quality by various methods used in several labs. showed good agreement of the results. By Tobler's micro method it is possible to exam. very small amts. for quality of the textile; it can also be used to test large amts. if care is taken to obtain an av. sample. Leopold Scheflan

Review of artificial German textiles. P. A. Koch. *Klepzig's Textil-Z.* **42**, 229–36, 307–10, 361–8, 464(1939). —An alphabetically arranged survey of artificial textile fabrics manufd. in Germany. Leopold Scheflan

The trend of progress in the cellulose textile industry. H. A. Thomas. *Silk and Rayon* **13**, 864, 866; *Rayon Textile Monthly* **20**, 639–40(1939); cf. *C. A.* **33**, 7117[3].—A review of recent developments in the production, dyeing, finishing and testing of cellulose fibers. II. *Silk and Rayon* **13**, 942–4; *Rayon Textile Monthly* **20**, 694–6(1939).— 5
The affinity of viscose rayon for wool dyestuffs has been increased by (1) mordanting the fiber with quaternary ammonium compds., (2) incorporation of proteins, such as casein, in the viscose spinning mass and (3) treatment of viscose filaments with reagents designed to combine with the cellulose to introduce basic groups or to form a basic resin in or with the fiber. Modifications of the fibers by (2) and (3) have resulted in new fibers of practical value. Viscose rayon is satisfactorily processed in the cake form. 6
This eliminates reeling into skeins and decreases the no. of knots. Modifications in the acetylation process for producing cellulose acetate are described. Mixed esters such as cellulose butyroacetate possess different properties from normal acetate fibers By stretch spinning, rayon of high tenacity is produced. Milton Harris

New methods for the improvement of fine woven textiles. A. Foulon. *Deut. Wirker-Ztg.* **59**, No. 34, 29–30 (1939).—A survey of new treatments including the dyeing of silk and rayon stockings and the dyeing, washing and wet-treating of other textiles. Several German patents in this field are discussed. Leopold Scheflan

Yarns and fabrics from sheep and Tiolan wool. R. Hünlich. *Spinner u. Weber* **57**, No. 38, 6–7(1939); cf. *C. A.* **33**, 7578[3].—A discussion of manufg., dyeing with various types of dyes and of drying. Leopold Scheflan

Contribution to the histology and pathology of the woolen fiber. Horst Reumuth. *Klepzig's Textil-Z.* **42**, 352–60, 495–510, 538–41(1939).—The structure of wool and the damage to wool caused by acids, alkalies, H_2O_2, Cl and other chemicals, and by fungi and bacteria are reviewed. 2
The Pauly reaction is suitable for damages that are not too large; it is unsuitable for damages in which all of the epidermis and subcutis have been destroyed. The following new method of prepg. pure stable diazobenzenesulfonic acid is given: To 50 g. of sulfanilic acid and approx. 25 g. KOH in 250 cc. soln., cooled thoroughly, add 200 cc. of cold 10% $NaNO_2$ soln., and drop by drop an ice-cooled soln. contg. 80 cc. concd. HCl and 40 cc. of water. 55 references and 48 figures. Leopold Scheflan

The pH value in the refinement of wool. Paul Müller *Deut. Wollen-Gewerbe* **71**, 915–17(1939).—A discussion of the importance of H-ion concn., methods of its detn., applications in fermentation sizing, alk. soap washing of textiles, fulling operations, bleaching with H_2O_2 and acid dyeing. Leopold Scheflan

Increasing the stability of silk to light by protective treatments. M. I. Babynichev and K. M. Markuze. *Shelk* **1938**, No. 10, 24–7; *Khim. Rejerat. Zhur.* **2**, No. 3, 128(1939).—The effect on light-stability of silk of treatment with tannin, hydroquinone, NH_4CNS, hydroxylamine, HCOONa, Na_2SO_3 and thiourea was investigated 4
Best results were obtained by treatment with thiourea; this was effective for 20-day insolation in summer under glass. The stability of silk to light is increased by increasing the alky. of the impregnating soln. However, silk dyed with Indanthrene Yellow 5 GK was less fast to light with increasing alky., owing to the catalytic action of the indigo dye with an increase of pH, which facilitates the intermediate formation of the leuco compd. W. R. H.

The roughening of cotton fabrics. Herberger. *Deut Wollen-Gewerbe* **71**, 1036(1939).—A discussion of suitable treatments. Leopold Scheflan

Theory of the viscometric method of determination of the wear-resistance of cellulose materials. A. A. Morozov. *Colloid J.* (U. S. S. R.) **5**, 525–40(1939).—A cotton fabric was repeatedly washed with a boiling soln. of 1% Na_2CO_3 and 1.5% soap, washed samples were dissolved in Cu NH_4 sulfate and the viscosity of the solns. was measured; η decreased almost linearly with the no. of washings. Detn. of η in a capillary viscometer at various pressures in a H_2 atm. showed that it was abnormal in 0.5 and 1% solns. Washings of the cotton fabric lowered the abnormal viscosity of its solns. to the same extent as the total viscosity, e. g., by 70% after 20 washings. A temp. increase from 20° to 30° lowered the η when its abnormal part was large, otherwise there was only a small change. J. J. B.

Viscosity of products of fractioning of cotton cellulose A. A. Morozov. *Colloid J.* (U. S. S. R.) **5**, 691–706 (1939); cf. preceding abstr.—Cotton (10 g.) was warmed with 1% NaOH and then kept for 20 hrs. in 1 l. of a soln. (I) contg. 1.35% of Cu, 15.5% of NH_3, and 0.2% of sucrose, or in 1 l. of this soln. dild. with $^2/_3$, 1, $1^1/_2$, or 2 vols. of H_2O. The resulting mixts. were injected into dil. AcOH soln. through a Cu gauze; the part remaining on the gauze was termed "insol. fraction" and that pptd. outside the gauze, "sol. fraction." Solns. of "sol. fractions" in I had higher viscosities than those of "insol. fractions" but the difference (and the values of both viscosities) decreased with the vol. of H_2O added to I. The structural part and the temp. coeff. of η also increased with dilu. of the initial Cu NH_4 soln., while the I no. of "insol. fractions" decreased. J. J. Bikerman

The chemical modification of cellulose, with some observations on the more recent developments in textile-finishing processes. J. Craik and W. R. Davis. *J. Soc. Dyers Colourists* **55**, 597–606(1939).—A consideration of: (*a*) the general trend in the development of cellulose derivs. and (*b*) some of the newer finishing processes and an outline of some older and better known products.

Among the latter are cellulose nitrate and acetate, viscose, ethyl- and benzylcellulose and methyl- and hydroxyethylcellulose. Under (*a*) cellulose esters and ethers are briefly discussed. There appears little prospect of important new cellulose ethers, sol. in org. solvents, coming to the fore. Cellulose mixed ether esters have shown no characteristics likely to justify their manuf. on a large scale. In the hydroxyethyl (glycol) cellulose, made by the action of ethylene oxide or ethylene chlorohydrin on soda cellulose, it is possible to prep. 3 classes of ethers. In the line of permanent finishes, the most promising materials are the hydroxyethylcelluloses and methylcelluloses. The corresponding cellulose glycolic acid can also be used, though the free — COOH group makes it much less permanent a finish when washed with soap. An ether made by the action of a half-mol. proportion of etherifying agent per $C_6H_{10}O_5$ unit of cellulose and completely and readily sol. at ordinary temps. in NaOH gives finishes not nearly as permanent as those from products made by the actions of, e. g., one-quarter mol. proportion of etherifying agent. The methods of application of these cellulose ethers are outlined. A proprietary softening agent resistant to laundering may be applied either before, after or with the cellulose ether. New and useful finishes on fabrics have been obtained by the use of waxes or resins as polyvinyl acetate, polyacrylic acid esters, certain glyptals and resin dispersed on the alkali solns. of the cellulose ethers. Means of prepg. these dispersions are outlined. The properties imparted to fabrics by the various permanent finishes are discussed from the points of: washing fastness, tensile strength, wearing properties and storage properties. Water-sol. cellulose ethers are used to some extent in the finishing of leather and textiles. They are neutral and extremely resistant to the action of light, alkalies and atm. oxidation but are not fast to washing. They are capable of holding very much larger proportions of inert fillers than starch. Water-sol. Na cellulose glycolate has a greater holding power for pigments than products of the methylcellulose type. The water-sol. cellulose ethers act as powerful protective colloids and are good emulsifiers for oils, waxes and fats, and may serve as adhesives and binding agents for clays and graphites. Recently aq. emulsions of certain cellulose derivs. have been introduced for the finishing of textiles. W. H. Boynton

The German rayons and staple fibers in photomicrographs. II. Staple fibers. B. Hauptmann. *Kunstseide u. Zellwolle* **21**, 447–50(1939); cf. *C. A.* **33**, 6057[2].—Photomicrographs of longitudinal and cross sections of 4 com. cellulosic fibers are reproduced. Mark Plunguian

Physical and chemical methods of testing staple rayon. Walther Schieber. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 266–74(1939).—Comparison of phys. properties of eleven grades of staple rayons with those of cotton and wool shows the superiority of the natural over the artificial textiles. A nitrate soln. diagram makes it possible to judge to a certain extent the packing density in a vegetable fiber material and its relation to the degree of polymerization and sp. wt. For the staple rayons examd. the packing density varied from 43–62%. The higher packing density indicates higher resistance against soln. and correspondingly better wet strength. Chain-length diagrams and soln. diagrams for eleven types of staple rayon are shown and discussed. The alkali soly. is inversely proportional to the mean degree of polymerization, in case of nearly uniform titer. The data indicate that (1) staple rayons of low mean degree of polymerization always have a greater soly. than those of higher degree of polymerization and (2) depending on the method of spinning used, special staple rayons show distinct differences, the cuprammonium process yielding the least favorable results. The detn. of the accurate compn. of staple rayons with regard to their mol. length was studied by (1) detg. the soly. of staple rayon in NaOH of const. concn. and different temps. and (2) nitrating staple rayon and subsequent fractional soln. of the fibers by means of mixts. contg. a solvent and a nonsolvent, e. g., Et acetate and alc. in different proportions. Reproducible results can be obtained with these methods only if they are carried out under const. conditions. Results obtained with them are shown in alkali soln. diagrams and nitrate soln. diagrams for Schwarza staple rayon. At different temps staple rayons of higher degree of polymerization were found to have a lower soly. than those with low and mean degree of polymerization. Another diagram illustrates the distribution of cellulose mols. of a fresh and a repeatedly washed and bleached fabric according to chain length; it indicates that the repeated washing and bleaching operations brings about a progressive alteration of the compn. in favor of smaller mol. lengths. Soln. diagrams obtained by the nitrate methods of two staple rayons of widely differing degrees of polymerization which had been manufd. under the same spinning conditions show that the low-polymer staple rayon contains consistently more constituents of easily sol. material. The results of all chem. and phys. tests show that there are relationships among soly., degree of polymerization, cleavage tendencies and frictional properties which make it possible to deduce the usefulness of a fabric and that high degree of polymerization of the fiber shows high quality and usefulness. 5 tables and 27 figures. Leopold Scheflan

New methods of evaluating staple fiber. Otto Eisenhut. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 261–5(1939).—The chem. methods of testing include the measurement of the mean degree of polymerization, fractional washing with NaOH of definite concn. at various temps., and the nitration of staple rayon and subsequent fractionation of the nitrates. It is recommended that the degree of polymerization be checked in all cases where a chem. disintegration of staple rayon may occur. The fractionation of the nitrates from staple rayons of different degrees of disintegration yields constituents with mols. of a degree of polymerization of 250. Staple rayons which are disintegrated to a smaller extent contain 40% of mols. of a degree of polymerization of 1000 while the highly degraded staple rayons contain only 10% of these mols. Similar results were obtained by washing these staple rayons with NaOH at different temps. Other examples of applications are discussed. Conclusions: The mech. and chem. properties of staple rayons differ from those of cotton owing to a difference in their phys. structure. The study of staple rayon and its control in industrial practice should be governed by more thorough methods of testing based on (1) accurate measurements of the strength-elongation properties and observations of the elastic and plastic properties of staple rayon, (2) measurement of the degree of polymerization and observation of staple rayon according to its compn. from different mols. of varying size during its manuf. and chem. alteration during processing, and (3) study of the splitting-up effect and its cause. 4 tables and 10 figures. Leopold Scheflan

Survey of the refinement of modern rayons and staple rayons. Max Peter. *Klepzig's Textil-Z.* **42**, 223–8, 393–4, 402–5, 410–12, 420–1, 450–2, 469–71, 478–80, 486–8, 524, 526, 534–5(1939).—226 references. L. Scheflan

Highly waterproof staple rayon. J. Harms. *Klepzig's Textil-Z.* **42**, 421; *Deut. Wollen-Gewerbe* **71**, 879–80 (1939).—Permanent waterproofing of staple rayon has

not yet been realized by hydrophobing or addns. to the spinning soln. Better results have been obtained by the use of very pure cellulose, careful treatment of cellulose during manufg. operations, better soln. of the xanthate and various changes in pptn. and aftertreatment baths. Leopold Scheflan

The oiling of staple rayons. B. Axhausen. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 242–4(1939).—An illustrated discussion of various com. installations and processes. Leopold Scheflan

Practical experiences in the sizing of staple rayon and rayon. Karl Walter. *Deut. Wollen-Gewerbe* **71**, 1093–6, 1121–4(1939).—The desirable properties of a good size are enumerated, an appropriate sizing process is described, the advantages of the use of dryer sizing machine are discussed, and special sizing formulas are given. L. S.

Testing knitted rayon fabrics. C. Eugene Coke. *Can. Textile J.* **56**, No. 21, 33–4(1939).—A discussion of results of laundering tests, the loss of strength during wear, instructions for washing rayon and the dry cleaning of dress goods. Leopold Scheflan

Production and equipment machinery for the manufacture of staple fiber and rayon goods. E. A. Anke. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 188–90(1939). L. S.

The sizing of rayon and staple rayon Herbert Brandenburger. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 240–1; *Spinner u. Weber* **57**, No. 31, 93–4, 96(1939).—A discussion of appropriate chem. and mech. treatments. Leopold Scheflan

Donegal. Kurt Hentschel. *Klepzig's Textil-Z.* **42**, 511–18(1939).—An illustrated description of chem. and mech. methods of manufg. Donegal textile fabrics in northwest Ireland. Leopold Scheflan

The manufacture and finishing of women's velour fabrics containing German shoddy. Erich Sellenk. *Deut. Wollen-Gewerbe* **71**, 890–1(1939).—A discussion of suitable chem. and mech. treatments. Leopold Scheflan

Felt and velvet. An alphabetical review of the common trade terms, names and designations for felts and velvets. Otto Pennenkemp *Spinner u. Weber* **57**, No. 26, 25–30 (1939) Leopold Scheflan

Methods of producing patterns on cloth. Hans Freytag. *Gebrauchsfotografie* **45**, 69–70(1938); *Phot. Ind.* **36**, 611. —The methods described are: (*a*) pictures produced on the cloth by the Fe gallate process, by Prussian blue or by Ag compds. are transformed into other metal compds. onto which basic dyes can be mordanted; (*b*) the cloth is made sensitive to light by means of diazo compds.; (*c*) cloth is sensitized to light by leuco dyes; and (*d*) colorless or colored org. substances make the cloth sensitive to light. A method of producing patterns on cloth belonging to the 1th group is described, in which grayish brown or brownish violet half-tones are produced by a 6-stage process. W. F. Berg

The nature of the shrinking [of textiles] and the problems of sanforizing finishing treatments. H. Rath. *Monatsh. Seide Kunstseide Zellwolle* **44**, 347–9(1939).—An address. Leopold Scheflan

New suggestions for the preparation of washproof and waterproof textiles involving the use of protein and protein compounds. Karl Erler. *Wollen- & Leinen-Ind.* **59**, 267–8(1939); *Chem. Zentr.* **1939, II**, 2865.—A discussion of the theory of porous, waterproof impregnations, the behavior of colloids, and double-bath methods for protein impregnations. A 20% soln. of egg albumin in cold water is reduced with 5% NaCl soln. to 1% albumin. The pH is adjusted to 4.5 by the addn. of AcONa and the textile is treated with this soln. in a suitable machine. Aftertreatments involve evapn., soaping and boiling at a pH of 7–7.5. Impregnations insol. in hot soap solns. are obtainable only with albumin which can be coagulated at the isoelec. point and which has been subjected to the double-bath treatment. Leopold Scheflan

Preservatives. Carl-Heinz Fischer. *Deut. Wollen-Gewerbe* **71**, 704–6(1939).—A crit. discussion of the simple, older preservatives used in the textile industry contg. derivs. of HClIO, phenol, salicylic acid, $ZnCl_2$, etc., as well as of modern products as Amicrol, Betol, chlorocresol, Preventol, Raschit, Salol and Shirlan. The new products are more effective and less harmful than the old. Leopold Scheflan

The textile chemical uses of sulfamic acid. J. Wakelin. *Am. Dyestuff Reptr.* **28**, 729–31(1939).—A recently discovered method for the relatively cheap production of sulfamic acid makes its use for a variety of textile uses more important. The addn. of Na or NH_4 sulfamate to solns. of soap or sulfated fatty alc. detergents for textiles is advantageous and improves the speed of dissolving and their ultimate soly. Sulfamates dissolve or disperse heavy metal salts. Alkali sulfamates prevent concd. solns. of soap from forming a gel when they cool. The amino H atoms of sulfamic acid are capable of being substituted by other radicals. W. H. Boynton

The cause, nature and significance of the Allwörden reaction. Curt Müller. *Klepzig's Textil-Z.* **42**, 329–33 (1939).—A crit. discussion of the value of the Allwörden reaction (*C. A.* **10**, 1436). The bubbles of the Allworden reaction are caused by the cells of the scales. The character of the bubbles is described as well as the behavior toward alkalies, acids and mech. factors and the formation of the bubbles by osmotic forces, whereby the wall of the bubble acts as a true membrane with selective permeability. The Allwörden reaction is not a generally applicable testing method. 13 references and 6 photomicrographs Leopold Scheflan

Undesirable electrolytic phenomena in the textile industry. H. Rammensee. *Klepzig's Textil-Z.* **42**, 481–2 (1939).—Several examples of unwanted electrolysis, corrosion, etc., in com. textile operations are discussed Leopold Scheflan

Can air be the cause of defects in textiles? Rudolf Schwarz. *Deut. Textilwirt.* **6**, No. 14, 20–3(1939).—Damages caused by the atm. are described and suitable air conditioning installations are discussed and shown. Leopold Scheflan

Calcium soaps: Defects caused by their formation Remedies. Joseph Rière. *Teinter* **4**, 514–19(1939).—The use of hard waters, in textile treating, causes the formation of undesirable Ca soaps R. points out the unevenness of dyeing and lack of fastness of dyes whenever these soaps are pptd. on or in the fibers. The common methods of *water softening* are discussed, such as heating, $Ca(OH)_2$, Na_2CO_3, Na_3PO_4, Permutite, AcOH, NaH_2PO_4, $Na_2H_2P_2O_7$, and protective colloids such as sulfonated fatty alcs. and their derivs. Saverio Zuffanti

The automatic production and control of low temperatures. Otto Th. Koritnig *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 307–8(1939).—An illustrated discussion of industrial installations for the textile industry. L. S

Progress in the technique of air conditioning. Conr. J. Centmaier. *Spinner u. Weber* **75**, No. 34, 35–7(1939) A survey of applications in the textile industry. L. S

Electrical air-conditioning installations [in the textile industry]. G. Firle. *Spinner u. Weber* **57**, No. 25, 8 (1939) Leopold Scheflan

Air-conditioning installations, the last stage in the development of the modern textile plant. Emil Gluckheh. *Deut. Wollen-Gewerbe* **71**, 838–44(1939).—Descriptive. Leopold Scheflan

Air-conditioning installations in the production and utilization of staple rayon and rayon. E. G. Schmidt. *Zellwolle u. Deut. Kunstseiden-Ztg.* **5**, 190–2, 236–40(1939) —A survey of com. installations and processes. L. S

Air conditioning plants for the production and processing of staple fiber and rayon. E. G. Schmidt. *Zellwolle u. Deut. Kunstseiden-Ztg.* **6**, 190–2, 236–8(1939).—An illustrated discussion. Leopold Scheflan

The impregnation with rubber of raincoat fabrics Kurialt. *Deut. Färber-Ztg.* **75**, 403(1939).—A discussion of chem. and mech. treatments. Leopold Scheflan

Slide fasteners from modern synthetic materials and their behavior toward the solvents used in chemical dry cleaning. Kuno Rickert. *Deut. Färber-Ztg.* **75**, 325–6 (1939).—Of a large no. of dry-cleaning and spotting solvents and solvent mixts. which were tested on slide fasteners manufd. from two German synthetic raw materials

only light petroleum and EtOH were entirely inert to both. Slide fasteners made from one of these two raw materials were resistant to more solvents than those made from the other raw material. The method of testing is described. Leopold Scheflan

Acid-resistant steel in the textile-refining industry. Hans Hougardy. *Spinner u. Weber* **75**, No. 30, 49–50, 53–6, 58(1939).—A survey. Leopold Scheflan

The application of rustproof and acid-resisting steels in the textile-refining industry. Werner Anhegger. *Spinner u. Weber* **57**, No. 34, 89–90, 93(1939).—An illustrated review with views of various types of machinery used. Leopold Scheflan

Modern dust-removal installations for the textile industry. H. Opitz. *Monatschr. Textil-Ind.* **54**, Fachheft 2, 1–2(1939).—Descriptive. Leopold Scheflan

Chemical precipitation of textile wastes and studies of pH control. Ralph Porges, Robert K. Horton, and Herman G. Baity. *Sewage Works J.* **11**, 828–63(1939).—The optimum pptn. of Sulfur Black waste appears dependent on mixing, flocculation and addn. of chemicals. Addn. of iron salts prior to acids reduces odors and favors better color removal owing to the formation of insol. Fe sulfide. By the addn. of inert materials such as coal, dust or sand more complete settling is obtained. For the treatment of kier liquors alum alone or alum and acid produce the best results. Cu and lime yield fair results. Carbonation by CO_2 and coagulation with $CaCl_2$ produces a poor effluent but offers possibilities as a cheap method for partial treatment. The best color removal for indigo waste liquor is obtained with lime, second best with alum and third best with $CaCl_2$. The most economical treatment is a combination of lime and copperas followed by flocculation. The resulting sludge dewaters rapidly. The most satisfactory treatments of vat dye waste were $FeCl_3$, alum, copperas in combination with lime and $Fe_2(SO_4)_3$. In the treatment of developed color waste the best and most economical results were obtained from copperas and lime. *Naphthol color dye waste* was successfully treated with H_2SO_4, $Fe_2(SO_4)_3$, alum and $FeCl_3$. Aniline black wash water was treated successfully with lime and alum. In general, results show that each coagulant appears to have a pH zone for optimum pptn., this zone being independent of the individual waste being treated. W. D. Hatfield

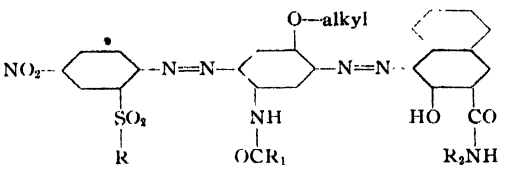
Analysis [of dyes] for traces of metallic impurities (Hess, *et al.*) 7. Modern methods for detn. of S and cystine in sheep wool (Schoberl, Rambacher) **11B**. Control of dermestids and clothes moths (Fremed) **13**. Alkylolaminomethylene compds. [dye intermediates] (U. S. pat. 2,169,736-7) **10**. Capillary-active compds. [for waterproofing fibers] (Brit. pat. 508,066) **13**. Aminoaryl sulfones [improving fastness of direct dyeings] (Brit. pat. 508,148) **13**.

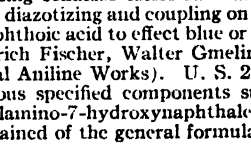
Azo dyes. Pierre Petitcolas (to Compagnie nationale de matières colorantes et manufactures de produits chimiques du Nord réunies, etablissements Kuhlmann). U. S. 2,169,162, Aug. 8. From components such as 2-diethylsulfonamido-5-methylphenylsulfonamidoaminobenzene and diacetoacetyl-*o*-tolidine and the like, azo dyes are produced which dye cotton yellow or orange shades and which have the general formula $1\text{-}(R_3R_4NSO_2)\text{-}4\text{-}(R_1R_2NSO_2)\text{-}2\text{-}(AN.N)C_6H_3$, in which R_1, R_2, R_3, R_4 are H or alkyl, aralkyl, aryl or cycloalkyl groups and A is the residue of a coupling component of the group consisting of the arylides of *o*-hydroxy carboxylic acids and of acylacetic acids.



Azo dyes. James G. McNally, Joseph B. Dickey and Werner H. Zugschwerdt (to Eastman Kodak Co.). U. S. 2,171,159, Aug. 29. From components such as 4-aminophenyl furyl ketone and barbituric acid and the like, dyes are obtained which dye cellulose acetate yellow to red or orange shades and which have the general formula RCO-R_2N NR_1 wherein R represents a furan, a thiophene or a pyrrole radical, R_1 represents a benzene nucleus, a naphthalene nucleus, a heterocyclic nucleus or a hydroaromatic nucleus and wherein the benzene nucleus designated R_2 may contain an alkyl group, an alkoxy group, a halogen atom or a nitro group. Numerous examples are given.

Azo dyes. Chester W. Hannum and Swanie S. Rossander (to E. I. du Pont de Nemours & Co.). U. S. 2,171,364, Aug. 29. From components such as H acid, α-naphthylamine, 1,6-Cleve's acid and cresidine, and the like, dyes are obtained which dye cellulose blue shades and which have the general formula

in which Aryl is a radical having a single benzene or naphthalene nucleus and Z is a radical having a single benzene nucleus and an amino group substituted thereon.

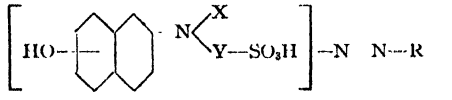


Azo dyes. Gerald Bonhote and Hans Johner (to Soc. pour l'ind. chim. à Bâle). U. S. 2,171,824, Sept. 5. From components such as 4-amino-5-methoxy-2-acetylamino-2′-methylsulfonyl-4′-nitroazobenzene and 3-hydroxy-2-naphthanilide and the like, dyes are formed which dye blue tints of good fastness and which have the general formula

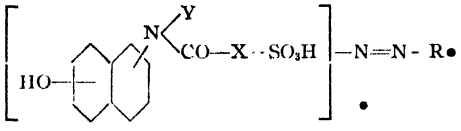
in which R stands for an alkyl, aralkyl or an aryl radical of the benzene series, R_1 stands for alkyl, O-alkyl, aralkyl or an aryl radical of the benzene series, and R_2 stands for an aromatic nucleus of the benzene and naphthalene series.

Azo dyes. Donovan E. Kvalnes (to E. I. du Pont de Nemours & Co.). U. S. 2,172,752, Sept. 12. From components such as 4′-amino-4-(ethylhydroxyethylamino)-azobenzene and 3-hydroxy-2-naphthoic acid and the like, dyes are obtained of the general formula $(H_2N)(X)C_6H_3N.NC_6H_3(Y)N(alkyl)(hydroxyalkyl)$ in which X and Y are each at least one of a group consisting of hydrogen, alkyl, alkoxy and halogen, and hydroxyalkyl contains at least 2 C atoms. These dyes are suitable for coloring acetate rayon, etc. U. S. 2,172,753 relates to the use of such dyes in dyeing cellulose esters such as cellulose acetate with further diazotizing and coupling on the fibers with 3-hydroxy-2-naphthoic acid to effect blue or black dyeings.

Azo dyes. Erich Fischer, Walter Gmelin and Richard Huss (to General Aniline Works). U. S. 2,175,794, Oct. 10. From various specified components such as aniline and 1-sulfoethylamino-7-hydroxynaphthalene, water-sol. azo dyes are obtained of the general formula



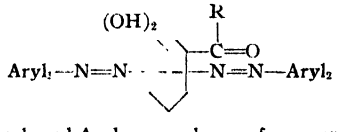
wherein R stands for a radical of the benzene series, X for H or the sulfonic acid group and Y for methyl or ethyl, being dark powders which penetrate deeply into *leather* and yield shades from violet to blue to black.



Azo dyes. Wilhelm Huber (to Soc. pour l'ind. chim. à Bâle). U. S. 2,178,417, Sept. 19. From components such as 2-cyano-4-nitro-1-aminobenzene and (ethylmethoxyethylamino)benzene and the like, dyes are ob-

tained which dye acetate rayon blue to violet shades and which have the general formula 2-($R_1R_2NAN{:}N$)-3-X-5-$NO_2C_6H_2CN$ wherein X represents H or NO_2, A represents an aromatic nucleus of the benzene and naphthalene series, and R_1 and R_2 represent H or alkyl, the amino group $—NR_1R_2$ standing in 4-position to the —N=N— group when A is a nucleus of the naphthalene series. Numerous examples are given.

Azo dyes. Erich Fischer and Walter Gmelin (to General Aniline Works). U. S. 2,175,795, Oct. 10. Monoazo dyes are produced of the general formula



wherein R means a radical of the benzene series not contg. a group lending solubility, X stands for H, methyl or ethyl, and Y for methane, ethane or propane residues, being brown powders which dye wool from an acid bath below boiling temp., at 60° to 90°, yellow-brown, brown-red to Bordeaux-red even shades. U. S. 2,175,796 relates to the production of water-sol. dyes of the general formula

wherein R means a radical of the benzene series not contg. a group lending solubility, Y stands for H, methyl or ethyl, and X for methane or ethane residues, being yellow-red to dark-red powders which dye wool in an acid bath below boiling temp., at 60° to 90°, orange-yellow, red to blue-red even shades.

Azo dyes. I. G. Farbenindustrie A.-G. Brit. 507,274, June 13, 1939. Water-insol. dyes are made in substance or on a substratum by coupling a diazo compd. of an amine of formula 2-Cl-4-$H_2NC_6H_3SO_2$-alkyl with 1-(2′,3′-hydroxynaphthoylamino)-4-ethoxybenzene. They yield orange shades fast to light and weather and may be used in the manuf. of lakes. In examples describing the prepn. of a dye in substance and on cotton yarn, the methyl sulfone is used as the diazo component.

Azo dyes from ring acylated phenols. Swanie S. Rossander and Harold E. Woodward (to E. I. du Pont de Nemours & Co.). U. S. 2,174,998, Oct. 3. From components such as diazotized *o*-aminophenolsulfonic acid and a dihydroxyphenone and the like, dyes are obtained which dye fast colors and which have the general formula

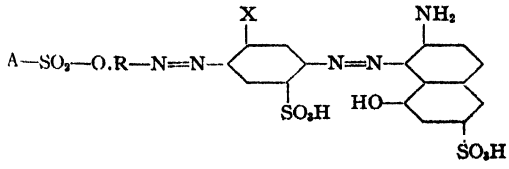
in which $Aryl_1$ and $Aryl_2$ are each one of a group consisting of the residues after diazotization of primary aryl amines, and R is the radical of one of a group consisting of straight- and branched-chain aliphatic hydrocarbons having at least 6 C atoms, aryl and aralkyl.

Chromiferous azo dyes. Walter Hanhart and Peter Pieth (to Soc. pour l'ind. chim. à Bâle). U. S. 2,171,828, Sept. 5. Cr-contg. azo dyes which dye wool and silk fast violet shades, etc., are produced by a process which involves heating azo dyes of the general formula of a 4-amino-1,5-naphthalenedisulfonic acid substituted in the 3-position by HORN:N— wherein R represents the radical of a diazo component the hydroxyl group of which stands in *o*-position to the azo group, with a trivalent Cr salt of HCl, HF or H_2SO_4 until on the one hand the complex Cr compd. of the azo dye has been formed, and, on the other hand, the NH_2 group of the naphthalene nucleus standing in *o*-position to the azo group has been exchanged for a hydroxyl group.

Azo compounds; dyeing and printing. Hans Z. Lecher (to The Calco Chemical Co., Inc.). Brit. 507,260, June 13, 1939. A diazotized aromatic or heterocyclic amine, not contg. a SO_3H or COOH group, is coupled with biguanide or a deriv. thereof that contains at least 1 H atom linked to a biguanide N atom but does not contain an aromatic or heterocyclic radical carrying a OH or amino group. Among examples, (1) diazotized 2-methyl-5-chloroaniline is added to a soln. of biguanide acid sulfate in NaOH soln., the azo compd. formed is filtered off and excess of biguanide is recovered from the filtrate by addn. of ammoniacal $CuSO_4$ soln., whereby a ppt. of Cu biguanide sulfate is obtained that may be decompd. with H_2S or Na_2S, and (2) diazotized 2-methoxy-4-nitroaniline or 2-methyl-4-nitroaniline is coupled with 1-phenylbiguanide. The azobiguanide compds. are generally stable to alkalies but easily decompd. by acids. They may be used in producing azo dyes on the fiber and for this purpose an alk. compn. contg. an azobiguanide compd. and an enolic or phenolic coupling component may be printed on the fibers and the dye then developed by treatment with an acid bath or with steam contg. an acid vapor. For use in such compns. the azobiguanide compds. may be treated with a deflocculating agent and a protective colloid with or without a wetting agent and a hydrotropic substance. Among examples, an aq. mixt. of 2-methyl-5-chlorobenzeneazobiguanide, 3-hydroxy-2-naphthoic acid *o*-phenetide, the Na salt of disulfodinaphthylmethane, Na_3PO_4 and dextrin is prepd. and dried, a printing paste is then prepd. by dispersing the product in aq. NaOH soln. and adding glycol monoethyl ether and starch-tragacanth thickener; printing is effected in the usual manner and the dye developed with steam contg. AcOH vapor, a scarlet print being obtained.

Monoazo compound. James G. McNally and Joseph B. Dickey (to Eastman Kodak Co.). U. S. 2,176,505, Oct. 17. From diazotized 1-amino-2,6-dimethoxybenzene and 1-phenyl-3-methyl-5-pyrazolone a monoazo deriv. is obtained which dyes cellulose acetate rayon yellow. Various similar yellow, red and brown dyes are described.

Monoazo dyes. Arthur H. Knight and Imperial Chemical Industries Ltd. Brit. 508,314, June 28, 1939. Dyes are made by coupling a diazotized *p*-nitroamine of the C_6H_6 series devoid of SO_3H and COOH groups with (a) an amine of the C_6H_6 series of formula *m*-AC_6H_4NXY, where X is alkyl, hydroxyalkyl, aryl, aralkyl or cycloalkyl, Y is an esterified hydroxyalkyl group, the ester residue being that of a dicarboxylic acid 1 COOH group of which is unesterified, which acid is either maleic acid or an aliphatic acid of formula $C_nH_{2n}(COOH)_2$, where C_nH_{2n} is a straight- or branched-chain hydrocarbon radical contg. 2–4 C atoms, and A is H, alkyl or halogen, or (b) a monoester of a 3-hydroxy-1,2,3,4-tetrahydroquinoline deriv. substituted in the 1-position by alkyl or aralkyl and in the 7-position by H, alkyl or halogen, and a dicarboxylic acid as above defined. Alternatively, the corresponding hydroxyalkyl dyes are monoesterified by reaction with anhydrides of the above dicarboxylic acids. The salts of the dyes are H_2O-sol. and are used for dyeing and printing acetate rayon. Among examples, (1) acetate rayon is printed with a paste contg. the azo dye 2-chloro-4-nitroaniline → the succinic ester of *N*-ethyl-*N*-β-hydroxyethylaniline, *N*,*N*-dibenzylsulfanilic acid, glycerol and an ammoniacal thickener, dried and steamed (bluish red), and (2) the dye *p*-nitroaniline → *N*-ethyl-*N*-β-hydroxyethylaniline is treated with maleic anhydride in dry tetrachloroethane.



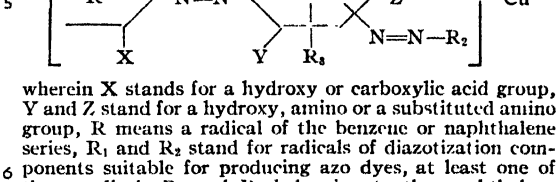
Monoazo dyes for cellulose esters and ethers. Emmet F. Hitch (to E. I. du Pont de Nemours & Co.). U. S. 2,173,054, Sept. 12. Dyeing is effected by applying to cellulose esters or ethers such as cellulose acetate rayon an aq. soln. of a dye such as may be formed from *N*-(*p*-aminobenzoyl)-*N*-methylglucamine or the like and which is represented by the general formula $Aryl_1—N=N—Aryl_2$ in which $Aryl_1$ and $Aryl_2$ are each one of a group consisting of benzene and naphthalene nuclei which are devoid of

sulfonic acid and carboxy groups, at least one of said aryl nuclei being substituted by a group $—(Z)_{n-1}NR_1R_2$ wherein Z is the radical —CO—, $—CH_2—$ or $—SO_2—$, n is 1 or 2, R_1 is a polyhydroxyalkyl radical having 4–6 C atoms and one fewer hydroxy group than C atoms, and R_2 is H, alkyl, hydroxyalkyl, dihydroxyalkyl or chlorohydroxyalkyl; and when $Aryl_1$ is substituted by a group $(Z)_{n-1}—NR_1R_2$ then $Aryl_2$ is substituted by one of a group consisting of hydroxy and said group $—(Z)_{n-1}NR_1R_2$; said application being carried out at a temp. of approx. 70° to 95° and until the fibers are dyed; and then washing the fibers. Such dyes dye orange and various other shades and numerous examples are given.

Monoazo dyes for cellulose esters and ethers. Emmet F. Hitch and Donovan E. Kvalnes (to E. I. du Pont de Nemours & Co.). U. S. 2,173,055, Sept. 12. Dyes giving red or other colored dyeings on cellulose esters and ethers such as cellulose acetate are formed from components such as *p*-nitroaniline and *N*-sorbityl-α-naphthylamine and the like and have the general formula of a naphthalene deriv. Aryl—N=N)-4-RHN-8-X-$C_{10}H_4Y$ in which aryl is a radical of the group consisting of primary amines of the benzene and naphthalene series which are devoid of carboxyl and sulfonic acid groups, X is H or hydroxy, Y is at least one of the group consisting of H, hydroxy, alkyl, alkoxy, halogen, amino, acetylamino, benzoylamino, NH-alkyl, —NH-hydroxyalkyl, dialkylamine and dihydroxyalkylamine, wherein the alkyl groups have one to three carbons, and R is a polyhydroxyalkyl group having 4 to C atoms and one fewer hydroxy than C atoms. U. S. 2,173,056 (Hitch, Kvalnes and Swanie S. Rossander, joint inventors; to same assignee) relates to dyes dyeing cellulose acetate or other cellulose esters and ethers orange or other shades, which may be formed from components such as β-naphthol and (*p*-aminobenzoyl)-*N*-methylglucamine and the like and have the general formula $R_1R_2N/_n(C_6H_3(X)(N{:}NE)$ in which R_1 is a polyhydroxyalkyl radical having 4–6 C atoms and one fewer hydroxy than C atoms; R_2 is H, alkyl, hydroxyalkyl, or halogen-substituted alkyl and hydroxy alkyl; Z is one of the radicals CO, $—CH_2—$ or $—SO_2—$; n is 1 or 2; X is at least one of a group consisting of H, alkyl, alkoxy and halogen; and E is an azo dye coupling component having no sulfonic or carboxyl groups and which may be of the hydroxybenzenes, anilines, naphthylamines, enols, phenylalkylpyrazolones or hydroxyquinolines, the azo bridge being connected to the benzene nucleus in one of the positions meta or para to Z. Numerous examples are given. Cf. *C. A.* **34**, 6341.

Disazo dyes. Wolfgang Alt and Hans Krzikalla (to General Aniline Works). U. S. 2,169,970, Aug. 15. Dyes of blue and other colors are obtained by coupling a diazo compd. of 4-amino-3-methoxydiphenylamine or 4-amino-4′-methoxydiphenylamine or the like with an *o*-hydroxyaryl carboxylic arylide contg. in the arylide portion at least one sulfonic acid group and corresponding to the general formula *o*-HO—Ar—CO—NH—B_1—NH—B_2—NH—B_3—NH—CO—Ar—OH—*o*, where Ar stands for arylene radicals and where B_1, B_2 and B_3 stand for phenylene radicals.

Disazo dyes. J. R. Geigy A.-G. Brit. 507,967, June 23, 1939. Dyes of formula

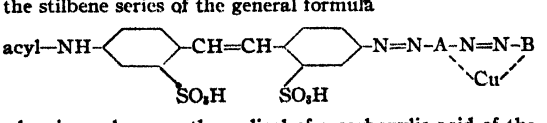


where X is H, alkyl or alkoxy, R is the residue of a phenol coupled in *p*-position and A is aryl, are made by coupling the diazo compd. of an amino monoazo dye corresponding to the above compd. with a phenol capable of coupling in *p*-position, and treating the disazo dye with an arylsulfonylchloride, or by coupling the diazo compd. of a monoazo dye of formula 2-H_2N-4-X-5-(HORN:N)$C_6H_3SO_3H$ with 2,8,6-acid in acid soln. and treating the disazo dye with an arylsulfonyl chloride. In examples, (1) the dye 4-nitro- or -acetylamino-1-aminobenzene-6-sulfonic acid → 2,8,6-acid is reduced or sapond., diazotized, coupled with phenol and the product treated with *p*-toluenesulfonyl chloride (I) (violet on wool), and (2) the dye 4-amino-4′-hydroxyazobenzene-3-sulfonic acid (from 4-nitro- or -oxalylamino-1-aminobenzene-3-sulfonic acid → PhOH and reduction or sapon., or by heating the dye 4-chloro-1-aminobenzene-3-sulfonic acid → PhOH with NH_3 under pressure) is diazotized and coupled with 2,8,6-acid in acid soln. and the product treated with I. Cf. *C. A.* **33**, 7585[1].

Diazoamino compounds. Albert Schmelzer and Eberhard Stein (to General Aniline Works). U. S. 2,173,324, Sept. 19. From initial materials such as diazotized 4-chloro-2-toluidine and 3-tetramethylene sulfone-glycine and the like, generally colorless to yellowish to brown cryst. compds. are obtained which have the general formula

$$[CH_2.SO_2.CH_2.CH_2.CHN(N—\text{alkylene}—X) : N—]_n—R$$

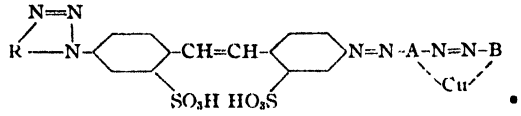
wherein R stands for an aromatic radical, free from carboxylic and sulfonic groups, X stands for an acid salt-forming group and n for 1 or 2, which can be used in the *prepn. of azo dyes* according to U. S. patents 1,882,560–1 (*C. A.* **27**, 849 and 852). Several examples with details are given.



Copper-containing azo dyes. Ernst Fellmer (to General Aniline Works, Inc.). U. S. 2,175,187, Oct. 10. Several examples are given of the production of brown dyes contg. Cu in complex form of the general formula

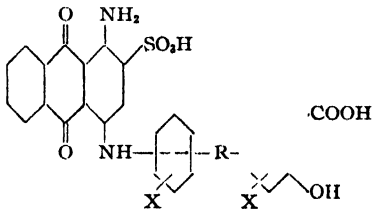
wherein X stands for a hydroxy or carboxylic acid group, Y and Z stand for a hydroxy, amino or a substituted amino group, R means a radical of the benzene or naphthalene series, R_1 and R_2 stand for radicals of diazotization components suitable for producing azo dyes, at least one of these radicals R_1 and R_2 belonging to the naphthalene series, and R_3 stands for a member of the group consisting or hydrogen, hydroxyl, alkyl, halogen, —COOH and $—SO_3H$, being in form of their alkali metal salts generally dark, water-sol. powders, dyeing *leather* generally even shades fast to light.

Dyes containing metals such as chromium and copper. Mordecai Mendoza (to Imperial Chemical Industries Ltd.). U. S. 2,174,591, Oct. 3. A process for the manuf. of metal-contg. dyes comprises treating with agents yielding metals having an atomic wt. between 50 and 64, those unsymmetrical azo dyes obtainable by coupling meta diamines of the benzene series having two free coupling positions with one mol. proportion of diazotized 3-amino-5-sulfosalicylic acid and one mol. proportion of a diazotized primary aryl amine other than the residue of ortho-coupled 5-sulfosalicylic acid; said primary aryl amine being one of a group consisting of aniline, monoaminonaphthalene, naphthylaminemonosulfonic acids, benzeneazonaphthylaminemonosulfonic acids and aminobenzenes substituted by at least one of the group consisting of nitro, hydroxy, alkyl, sulfonic acid, carboxyl, azobenzene, azobenzenesulfonic acid and $HO_3SC_6H_4NH—$.



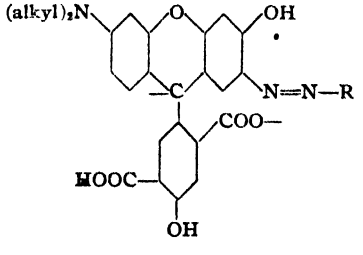
Copper complex compounds of disazo dyes of the stilbene series. Hans Schindhelm (to General Aniline Works). U. S. 2,175,815, Oct. 10. Details are given of the production of Cu complex compds. of disazo dyes of the stilbene series of the general formula

wherein acyl means the radical of a carboxylic acid of the



aliphatic or the benzene series and A and B stand for sulfonated radicals of the naphthalene series which contain in *o*-position to the azo group a group capable of being metallized, which Cu complex compds. dye vegetable fibers green to greenish gray shades of excellent fastness to light.

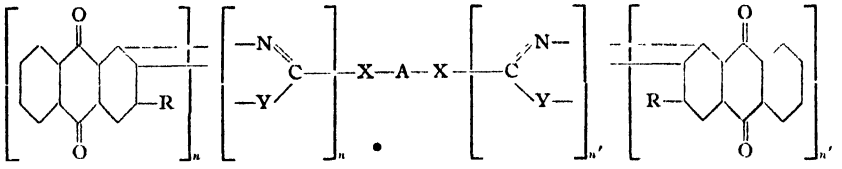
Copper complex compounds of polyazo dyes of the stilbene series. Hans Schindhelm and Carl T. Schultis (to General Aniline Works). U. S. 2,175,652, Oct. 10. Various examples with details are given of the production of Cu complex compds. of polyazo dyes of the stilbene series of the general formula



wherein R stands for a sulfonated radical of the naphthalene series and A and B stand for sulfonated radicals of the naphthalene series contg. in *o*-position to the diazo group a group capable of being metallized, which dyes dye vegetable fibers green shades of good fastness, especially to light. Cf. *C. A.* **33**, 5197[4].

Chromium-containing dyes. Erich Fischer (to General Aniline Works). U. S. 2,174,823, Oct. 3. Dyes which dye wool violet, blue, gray or green are produced by the action of Cr-yielding agents such as Cr acetate or formate on anthraquinone compds. of the general formula

wherein X represents H, CH_3, Cl, methoxy or sulfonic acid, and R represents $—CH_2SO_2—$, —CONH—, $—CH_2—$ or —CO—.

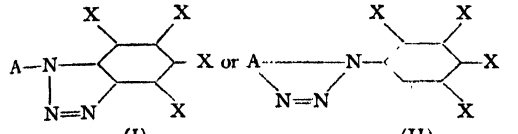


Chromable dyes of the triarylmethane series. Wilhelm Eckert and Karl Schilling (to General Aniline Works). U. S. 2,175,716, Oct. 10. Various examples are given of the production of fast chromable dyes, dyeing various colors and of the general formula

where R means the residue of a diazotizable arylamine of the benzene or naphthalene series and alkyl means methyl or ethyl. Cf. *C. A.* **34**, 892[4].

Vat dyes. I. G. Farbenindustrie A.-G. Brit. 508,393, June 30, 1939. Dyes of formula $RNHCOC_6H_4N:NC_6H_4$-CONHR, where R is the radical of a vattable ring system, or the corresponding imidazole, oxazole or thiazole derivs., are made by converting such *N*-aroyl derivs. of amines of vattable ring systems, or their imidazole, oxazole or thiazole derivs., as contain in the aroyl radical an amino or NO_2 group, by an oxidation or reduction process, resp., into the corresponding azo compds. Among examples, (1) 1-(3'-nitrobenzoylamino)anthraquinone is reduced by means of Zn dust and NH_4OH in dioxane soln.; the product dyes cotton from a red vat lemon-yellow shades, and (2) μ-(4'-aminophenyl)-2,1(*N*)-oxazoloanthraquinone is oxidized by means of NaClO in aq. Na_2CO_3 soln.

Vat dyes of the anthraquinone series. Ernst Honold and Max Schubert (to General Aniline Works). U. S. 2,175,803, Oct. 10. Dyes which dye vegetable fibers from the vat yellowish shades of good fastness to Cl and boiling soap soln. and, in many instances, to light, have the general formula



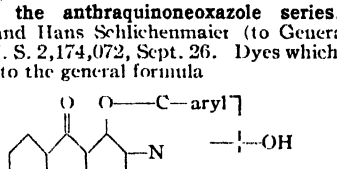
wherein R stands for H or halogen, *n* and *n'* stand for one of the numbers 1 and 2, Y for a member of the group consisting of —S— —O— and —N=, X for a member of the group consisting of the phenylene, halogenated phenylene, alkoxyphenylene, the naphthalene, the biphenylene radical, the radical of biphenylene oxide, fluorene, carbazole and diphenyl sulfide, and an *ar*-aliphatic radical (*ar* meaning the phenyl radical), A stands for a member of the group consisting of —N N—, —N(:O) N—, —N NX_1N.N— and —N(:O) NX_1N.N(:O)—, X_1 meaning a member of the group consisting of the biphenylene, azobenzene and benzophenone radical, the pairs of X, Y, *n* and n_1 having identical value, and are obtainable by condensing such amines of the anthraquinone series as contain in ortho position to the amino group a further amino group or a hydroxy or mercapto group, which amines are able to form an imidazole or oxazole or thiazole ring during the condensation reaction, with carboxylic acids of the general formula: $(HOOC)_n—X—A—X—(COOH)n'$, wherein *n*, *n'*, X, A and X have the above said signification, or their functional derivs. Advantageously the condensation reaction is performed in org. solvents. By acting with the carboxylic acid chlorides of the said azo or azoxy compounds on the amines condensation occurs in some cases at room temp. The condensation reaction is finished at elevated temps. whereby simultaneously the formation of the azole ring is performed.

Vat dyes of the dipyrazoleanthrone series. Werner Zerweck and Eduard Gofferje (to General Aniline Works) U. S. 2,176,443, Oct. 17. By reactions such as cyclohexylating and alkylating dipyrazoleanthrone, *N*-cyclohexyl-*N'*-alkyldipyrazoleanthrones are obtained which form leuco compds. of good soly. and give bright yellowish red fast dyeings on cotton.

Dyes of the anthraquinone series. Chemische Fabrik vorm. Sandoz. Brit. 508,742, July 5, 1939. Compds. of the formula of a 1-(benzanthronylamino)anthraquinone substituted in the 4-, 5- and 8-positions by H or an amino, alkylamino, alkylolamino or arylamino radical and in which the arylamino, anthraquinone and benzanthrone radicals may be substituted but must not contain aroylamino groups, are treated with sulfonating agents. Substituents specified are halogen, CN, OH, alkoxy, phenoxy and alkyl. The products are H_2O-sol. and dye wool gray, reddish brown or yellow shades. Among substances treated in the examples are (1) 1-(*Bz*-1-benzanthronylamino)anthraquinone and its substitution products contg. in 4-position of the anthraquinone nucleus the radicals

(a) anilino, (b) *o*- or *p*-toluino, (c) *p*-acetamidoanilino, (d) *o*- or *p*-chloroanilino, (e) 2,5-dichloroanilino, (f) *p*-aminoanilino, (g) *p*-phenylanilino, (h) ethanolamino, etc., (2) 1,4-anilino-*Bz*-1-(6-bromo- or 2-methyl-benzanthronylamino)anthraquinone.

Vat dyes of the phthaloylcarbazole series containing trifluoromethyl groups. Hans Schlichenmaier, Hans Hoyer and Ludwig W. Berlin (to General Aniline Works). U. S. 2,174,182, Sept. 26. Vat dyes which are given improved fastness or color by the presence of trifluoromethyl groups are obtained by transforming into carbazoles according to known processes compds. of the formulas



(I) (II)

wherein A is the radical of an anthraquinone compd., at least one X stands for a trifluoromethyl radical and the other X's are H or any substituents, two adjacent ones of which may also be members of a further ring system; or similar anthraquinone compds. contg. the azimide radical twice. Several examples with details are given.

Anthraquinone acid wool dyes. Henry R. Lee and David X. Klein (to E. I. du Pont de Nemours & Co.). U. S. 2,170,385, Aug. 22. Acid wool dyes which dye wool blue shades have the general formula of a 1-amino-5-nitro 2-anthraquinonesulfonic acid or its alkali metal salt substituted in the 4-position by an arylamino radical of the benzene series such as that of aniline or *p*-aminomethylacetanilide.

Dyes of the anthraquinoneoxazole series. Georg Kranzlein and Hans Schlichenmaier (to General Aniline Works). U. S. 2,174,072, Sept. 26. Dyes which probably correspond to the general formula

wherein aryl comprises radicals of the group consisting of phenyl and phenyl substituted by noncyclic univalent substituents and the position of the hydroxyl and sulfo groups in the molecule is not known, and the alkali metal salts thereof, which may be after-chromed to obtain fast greenish blue dyeings, are obtained by causing H_2SO_4 contg. free SO_3 to act upon 4-aminoanthraquinone-1,2-(N)-aryloxazoles (suitably at a temp. of 60–160°). Several examples with details are given.

Dyes and intermediates. I. G. Farbenindustrie A.-G. Brit. 508,029, June 23, 1939. Benzanthrone derivs. are made by causing a *Bz*-1-alkoxybenzanthrone, or a *Bz*-2-carboxylic acid or ester thereof, to react with a primary aromatic amine, which may be a vattable compd., in the presence of a caustic alkali, the ester group when present being sapond. during the reaction. The reaction is preferably conducted in the presence of an indifferent solvent. Depending on conditions, *Bz*-1-arylaminobenzanthrones or the benzanthronehydroacridines resulting therefrom from ring closure thereof are formed, the former being capable of transformation into the latter by fusion with caustic alkali. The products are dyes or intermediates thereof. Among examples (1) *Bz*-1-methoxybenzanthrone (I) is heated with $PhNH_2$ in the presence of KOH and pyridine to yield *Bz*-1-anilinobenzanthrone, (2) I is heated with *Bz*-2-aminobenzanthrone in the presence of KOH and pyridine to produce *Bz*-1,*Bz*'-2-dibenzanthronylamine; by fusion of this with KOH and alc. the corresponding hydroacridine, which dyes cotton violet shades from a bluish red vat, is produced and (3) Me I-*Bz*-2-carboxylate is heated with 2,4-dichloroaniline in the presence of KOH and pyridine to produce *Bz*-1-(2',4'-dichloroanilino)benzanthrone-*Bz*-2-carboxylic acid.

Dyes and intermediates of the anthraquinone series. Artur Krause and Robert Zell (to General Aniline Works). U. S. 2,174,245, Sept. 26. Intermediates or dyes giving clear fast red to violet dyeings on cellulose acetate, etc., are produced by reaction of compds. such as 1-amino-2,3-dihydroxypropane, glucamine, alkylglucamines and similar amines of the sugar series with anthraquinone derivs. such as 1-nitroanthraquinone-2-carbonyl chloride, 1-chloroanthraquinone-2-carbonyl chloride, 1-aminoanthraquinone-2-carbonyl chloride, 1-amino-4-nitroanthraquinone-2-carbonyl chloride, 1-amino-4-(*p*-toluenesulfamido)anthraquinone-2-carbonyl chloride, 1,4-dichloroanthraquinone-6-carbonyl chloride, 1,4-bis(*p*-toluenesulfamido)anthraquinone-6-carbonyl chloride, 1-iodoanthraquinone-2-sulfonyl chloride, 1,4-dichloroanthraquinone-2-sulfonyl chloride, 1,4-dichloroanthraquinone-6-sulfonyl chloride and 1,5-diaminoanthraquinone-2,6-dicarbonyl chloride The reaction is preferably carried out in the presence of water, an alc., pyridine or a diluent.

1,3-Diazaanthraquinones. Fritz Baumann and Heinz W. Schwechten (to General Aniline Works). U. S. 2,176,413, Oct. 17. *Intermediates for the production of vat dyes, acid wool dyes* or *pigment dyes* are produced by subjecting a 6,7-benzoquinazoline to oxidizing agents such as an excess of chromic acid in the presence of H_2SO_4. Details are given of the production of: 1,3-diaza-2-hydroxy-4-phenylanthraquinone from 2-hydroxy-4-phenyl-6,7-benzoquinazoline; 1,3-diaza-2,4-dihydroxyanthraquinone from 2,4-dihydroxy-6,7-benzoquinazoline; 2-phenyl-4-hydroxy-1,3-diazaanthraquinone from 2-phenyl-4-hydroxy-6,7-benzoquinazoline; and a corresponding oxidation product from 2-(1'-nitro-2'-anthraquinonyl)-4-hydroxy-6,7-benzoquinazoline.

Halodialkoxyisodibenzanthrone compounds. Edward T. Howell (to E. I. du Pont de Nemours & Co.). U. S. 2,170,381, Aug. 22. Blue *dyes* and *intermediates* are obtained by introducing Cl or Br into *Bz*-2,*Bz*-2'-dialkoxyisodibenzanthrone compds., either by direct halogenation or by halogenation of intermediates with subsequent oxidation and alkylation. Details are given of the production of 6-chloro-*Bz*-2,*Bz*-2'-dimethoxyisodibenzanthrone, a brominated dihydroxyisodibenzanthrone, a dibromodihydroxyisodibenzanthrone, a tetrabromodihydroxyisodibenzanthrone, a dibromodimethoxyisodibenzanthrone, a monobromodimethoxyisodibenzanthrone, a brominated dimethoxyisodibenzanthrone contg. somewhat in excess of 2 atoms of Br and a dibromo-*Bz*-2,*Bz*-2'-diethoxyisodibenzanthrone. Bromination may be effected in H_2SO_4 or $ClSO_3H$, or the halogenation may be carried out in an org. solvent such as $PhNO_2$ or in aq. suspension, and I or other halogenation catalyst may be used.

***peri*-Naphthindenones.** Karl Koeberle, Werner Rohland and Christian Steigerwald (to General Aniline Works). U. S. 2,174,751, Oct. 3. *peri*-Naphthindenones contg. one or two of the groups $-NR_1R_2$, where R_1 and R_2 stand for H or alkyl, aryl acyl or heterocyclic groups, are obtained by condensing halogenated naphthindenones with arylsulfonic acid amides and saponification of the arylsulfonamidonaphthindenones thus formed, or by causing alkylamines, arylamines or heterocyclic amines, or amides of org. carboxylic acids to react with halogenated naphthindenones or by acylation or alkylation or arylation of aminonaphthindenones. Details are given of the production of compds. such as 2-aminonaphthindenone, m. 127–8°, 2-benzoylnaphthindenone (dyeing artificial silk yellow), dinaphthindenonylaminoanthraquinone (dyeing cotton red-yellow shades from a violet vat), 2-dimethylaminonaphthindenone (dyeing artificial silk reddish yellow shades), 2-dodecylaminonaphthindenone (a red powder), 2-anilinonaphthindenone, 1-(naphthindenon-2-ylamino)-2-carboxylic acid, m. 248–9°(decompn.), 2-(1-anthraquinonylamino)naphthindenone (giving a red vat), 2-naphthindenonylamino-1,9-anthrapyrimidine (giving a red vat), 6-(1-anthraquinonylamino)-2-chloronaphthindenone (giving a yellow-red vat) and

2-(1-anthraquinonylamino)-6-pyrazoloanthronylnaphthindenone, and mention is made of the production of various other similar compds. by like reactions. As initial materials for the said reactions, there may be used, e. g., 2-chloronaphthindenone, 2-bromonaphthindenone, 2,6-dibromonaphthindenone, 2-chloro-6-bromonaphthindenone, 2-aminonaphthindenone and 2-amino-6-bromonaphthindenone, and the like. The reactions are preferably carried out in the presence of org. diluents, such as isobutanol, AmOH, nitrobenzene, mono-, di- or trichlorobenzene or naphthalene and of agents capable of combining with acids such as alkali carbonates, $CaCO_3$, $MgCO_3$ and alkali acetates and substances favoring the reaction, such as Cu compds. In many cases it is preferable to carry out the reaction under superatm. pressure.

Dyeing. I. G. Farbenindustrie A.-G. Brit. 507,528, June 16, 1939. Azo dyes are made on the fiber by applying to cotton or regenerated cellulose compds. that possess affinity for cellulose fibers, contain at least 1 SO_3H group and contain diazotizable amino groups, diazotizing and developing by treatment with enolizable hydroaromatic carbocyclic β-diketones. The substances possessing affinity are substantive dyes or substantive compds. that are not dyes. Greenish yellow shades are obtained. In examples, cotton is treated with bis(*p*-aminobenzoyl)-1,4-diaminobenzene-2-sulfonic acid or bis(*p*″-aminobenzoyl-*p*′-aminobenzoyl)-4,4′-diaminostilbene-2,2′-disulfonic acid, diazotized and developed with 5,6-dimethyl-1,3-cyclohexanedione, 5-phenyl-1,3-cyclohexanedione, 4-isobutyl-1,3-cyclohexanedione or 1,3-diketodecahydronaphthalene.

Dyeing regenerated rayon in tightly wound packages. Theodoor Koch (to American Enka Corp.). U. S. 2,176,403, Oct. 17. The package is impregnated with an alk. dye soln. contg. a water-sol. aliphatic alc. such as MeOH or iso-PrOH to prevent swelling of the threads so that even passage of the dye soln. through the package is effected.

Preparing fibers from plant materials such as pineapple leaves, flax, hemp and jute. Frederick P. Gardner. U. S. 2,177,646-7, Oct. 31. Various details of app. and operation.

Preparing cloth for fulling. Roland E. Derby (to M. T. Stevens & Sons Co.). U. S. 2,176,706, Oct. 17. App. is described, and a method of continuously and progressively prepg. for fulling cloth contg. animal fiber, as it comes from the loom, which comprises simultaneously performing in sequence upon a continuous web of the cloth the following steps, first, continuously, progressively and successively (*a*) passing the cloth through a bath of a liquid solvent for oleaginous foreign substances contained in the cloth, (*b*) extg. by suction the principal part of the solvent and solvent-retained foreign substances remaining in the cloth, (*c*) heating the cloth sufficiently to vaporize the solvent remaining therein and (*d*) sepg. the cloth from the solvent vapor; second, continuously, progressively and successively (*a*) moistening the cloth, (*b*) passing the moistened cloth through an acid bath and (*c*) expressing the acid from the cloth; third, (*a*) continuously and progressively stretching the cloth to a predetd. width and while maintained thus stretched continuously and progressively drying the cloth and (*b*) then continuously and progressively baking the cloth to carbonize foreign vegetable material therein; and, fourth, continuously and progressively subjecting the cloth to a plurality of crushing operations to free the carbonized material therefrom.

Sizing and impregnation of textile materials. Stanley L. Kirkendall (to Owens-Corning Fiberglas Corp.). U. S. 2,177,323, Oct. 24. App. is described, and a method of controlling the sizing and impregnation of textile materials by passing the material through a soln. of the sizing material and impinging jets of gaseous fluid such as air under pressure against the material at an acute angle to it and contra to its direction of motion to remove excess sizing material and to force the retained sizing material into the textile.

Sizing textile fabrics such as cotton broadcloth. Wyly M. Billing (to Hercules Powder Co.). U. S. 2,176,053, Oct. 17. **A sized fabric of stiff and starch-like finish in the absence of starch and pliable and pervious to moisture and to air has its individual threads discontinuously impregnated with about 5–40% of a compn. comprising a solid thermoplastic material such as a compn. of chlorinated rubber, ethyl cellulose or cellulose acetobutyrate substantially resistant to the action of aq. alk. solus., and has directly adjacent threads bonded together by the thermoplastic material, which however does not fill the interstices.**

Softening textile materials. Otto Albrecht (to Soc. pour l'ind. chim. à Bâle). U. S. 2,175,101, Oct. 3. Softening of materials such as viscose rayon is effected by treatment with an aq. soln. of the NH_4 salt of hexahydrophthalic acid oleyl alc. monoester or other product of the general formula MOC(:O)AYZ in which M stands for an alkali metal or NH_4, A for an unsulfonated aryl radical of the benzene series, Y for a —C(:O)O— group which is attached to the aryl radical A by means of the C atom and Z for an aliphatic radical having at least 8 C atoms in a straight chain.

Use of solvents for removing oleaginous and foreign substances from webs of fibrous material, as in removing tar from wool cloth. Roland E. Derby (to M. T. Stevens & Sons Co.). U. S. 2,176,705, Oct. 17. Various details of app. and operation for the treatment of continuous webs passed through a solvent bath.

Conditioning acetate rayon yarn, etc., with diethyl octyl phosphamate and related compounds. Joseph B. Dickey and James G. McNally (to Eastman Kodak Co.). U. S. 2,172,241, Sept. 5. A process of conditioning yarn to render it more amenable to textile operations including knitting, weaving, spinning, etc., comprises applying a lubricating and softening compn. contg. as its essential lubricating and softening component a P compd. having the general formula: $BB_1P(:X)OR$ where X is O or S, R is alkyl or aryl; B is —O—R or B_1; B_1 is —NR^1R^2 and R^1 and R^2 are H, alkyl or alkaryl. Cf. *C. A.* 33, 8123[9].

Compositions suitable for lubricating yarns of cellulose acetate, etc. Edwin A. Robinson (to Eastman Kodak Co.). U. S. 2,176,510, Oct. 17. A water-insol. oil such as a white mineral oil is dispersed in an aq. vehicle by use of a sulfonated wax such as sulfonated spermaceti wax.

Lubricating composition for treating rayon. Theodoor Koch (to American Enka Corp.). U. S. 2,176,402, Oct. 17. A lubricating compn. suitable for treating rayon comprises a soln. formed of a mixt. of mineral oil, Bu stearate, a substituted hexylamine such as diethylcyclohexylamine and a solvent such as oleic acid.

Waterproofing textiles. I. G. Farbenindustrie A.-G. Brit. 507,628, June 15, 1939. Fibrous materials, e. g., cotton, wool, silk, viscose, are rendered water-repellent by impregnation with an isothiourea salt contg. the group —CH_2XR or —$CH_2X'R'$, wherein R is an aliphatic, aliphatic-cycloaliphatic or aliphatic-aromatic radical contg. at least 11 C atoms, which may contain substituents and (or) may contain an O, S or N atom as a hetero atom in an aliphatic C chain or as a bridge directly linking an aliphatic portion of the radical to a cycloaliphatic or aromatic nucleus, R′ is an alkyl radical, X is O, S or phenoxy or the group —CO.N(R″)—, —O.CO.N(R″)— or —NH.CO.N(R″)—, wherein R″ is H or alkyl, and X′ is —CO.N(R)— or —O.CO.N(R)—, and subjection of the impregnated material to heat treatment at about 80–150°. Typical compds. are *S*-octadecyloxymethylisothiourea-HCl, *S*-stearoylaminomethylisothiourea-HCl, the reaction product of 4-dodecyl-2-chloromethylphenol and thiourea, *S*-stearoylaminomethyl-*N*-dodecyloxymethylisothiourea-HCl (prepd. from stearic acid chloromethylamide and dodecyloxymethylthiourea, the latter being prepd. from dodecyloxymethyl isothiocyanate and NH_3) and the reaction product of thiourea or a compd. thereof with a halomethyl compd. prepd. by the action of CH_2O or a polymer thereof on stearonitrile. The compds. may be used in the presence of buffering substances and may be applied in soln. in an org. solvent or in aq. solns. or dispersions at 0–100°. The impregnated material may be

preliminarily dried at up to 80° prior to the heat treatment. The compds. may be applied in admixt. with other water-proofing agents and the treatment may be combined with softening, delustering, etc., processes.

Mothproofing solution. Wm. H. Engels and John Weijlard (to Merck & Co. Inc.). U. S. 2,176,894, Oct. 24. A stable soln. suitable for treating various fabrics contains triethanolamine fluosilicate, $Al_2(SO_4)_3$ and a sol. wetting agent such as lauryl sulfate and is substantially free from uncombined silicic acid. Cf. *C. A.* **33**, 5678[9].

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

Progress in paints for exposure in Cuba. Wm. D. Roland. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* 1938, 163-70.—The chief difficulties to be met are slow drying, blackening from mildew, rapid bleaching of color, and poor durability; these are counteracted by choice of drying agent and mildly toxic pigments. With special reference to sugar factories, the corrosion-inhibiting properties of Pb and Zn chromates make them superior to red lead; they are recommended as primers for outdoor painting. It is definitely established that even the highest grades of bituminous paints are inferior to oil paints. Synthetic-resin varnishes are recommended for resistance to chem. attack, and black asphaltum coatings for resistance to cold or hot sirups. O. W. Willcox

Accelerated weathering of paints. Ontario Research Foundation. *Bull. Ontario Research Foundation*, Reprint, 3
P. No. **339**, 3-7; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 397(1939).—A report of tests using the Weather-Ometer. George Ayers

Economizing oil in paints with special consideration of weather resistance. M. Hess. *Oil Colour Trades J.* **96**, 1284-4, 1288(1939).—The oil requirement depends to a much greater extent on the degree of fineness and the shape of the particles than on the chem. characteristics of the pigment. Stand oil is more weatherproof than boiled oil. H. considers the use of stand oil of a suitable viscosity, the addn. of pure phenolic resins to the drying oils, combination of refined fish oils with film-forming oils, use of synthetic wood oils, air-blown linseed oils, perhaps with an addn. of pure phenolic resins or use of alkyd resins contg. at least 50% of oil, cellulose products, and greater use of products based on chlorinated rubber, asphalt, bitumen and pitch. W. H. Boynton

Traffic paint. Leroy Shuger. *Drugs, Oils & Paints* **54**, 111-16, 118(1939); cf *C. A.* **34**, 2753.—Essential requirements of a traffic-paint method of test are noted. Properties covered are flexibility and abrasion resistance. Lab. tests are outlined. A wear-testing machine is described and illustrated. W. H. Boynton

Moisture peeling of house paints. Mechanism of moisture peeling. J. W. Iliff and R. B. Davis. *Ind. Eng. Chem.* **31**, 1446-50(1939); cf. *C. A.* **34**, 6435.—The mechanism discussed is essentially confirmatory of the conclusions of prior investigators (cf. Browne, *C. A.* **27**, 4940, and Teesdale, *C. A.* **34**, 6437). F. L. B.

The advance of synthetic-resin paints in corrosion prevention. G. Koken. *Chem. Fabrik* **1939**, 502-4.—Historical, with comments on the type of paint best suited to purposes. J. H. Moore

Covering power" determination. A. Davidsohn. 8
Paint Manuf. **9**, 340(1939); cf. *C. A.* **33**, 8039[6].—Glass slides 25 sq. cm. in area are cut accurately to permit insertion in another accurately cut glass sheet. The small slides may be inserted in the corresponding empty space of the large glass sheet and then brushed in the usual manner with an ordinary brush. The small glass slide is then withdrawn and the wt. increase detd. both in the fresh condition and after 48 hrs. This permits measurement of the consumption of pigment-paint (*a*), the wt. of the coat (*b*) and, if the sp. gr. of the paint is known (*s*), also of the film thickness (*c*). *a* and *b* can be directly weighed in respect to the 25 sq. cm. surface, while *c* (in cm.) is calcd. from the equation $c = b/s.25$. Once the single or double coating of paint is dry, the slides are fitted into the window lattice and the light-transparency examd. preferably in comparison with a suitable standard. Photographs of the tests can be made. The method does not possess the accuracy of photocell methods but is suitable for routine examn. of light transparency of paints. W. H. Boynton

Wall paintings in the Bagh caves—investigation into their methods. S. Paramasivan. *Proc. Indian Acad. Sci.* **10A**, 85-95(1939).—See *C. A.* **34**, 6432. H. G.

Titanium pigments. J. A. Lutz. *Am. Paint J.* **24**, 3
50, 52-7(Dec. 18, 1939).—A general discussion of the pigment properties of the Ti pigments. The paints are discussed under the headings of: (1) exterior house paints, (2) interior finishes and (3) industrial paints. Several formulas are included. W. H. Boynton

A practical hiding power comparison of lithopone and titanium-calcium pigments in commercial flat-wall paints. J. C. Thompson, Jr. *Drugs, Oils & Paints* **54**, 408, 410, 412, 414(1939).—A study of the dry hiding power and the effects of such factors as: (1) volatile in the vehicle, (2) wetting power of the vehicle, (3) ratio of pigment vol. to nonvolatile vol. (PFV), (4) flocculation of the pigment, (5) oil absorption of the pigment and the inert and (6) influence of the pigment-inert ratio. No fixed hiding power can be detd. for any pigment, lithopone and Ti-Ca pigment varying in hiding power per lb. from a min. value of about 23.5-58.5 sq. ft. for lithopone and from 30.5 to about 67 sq. ft. for Ti-Ca. The relative "dollar hiding value" comparison of the 2 pigments shows an edge for lithopone. The comparison was made on 95 com. paints obtained in all parts of the U. S. and significant results are shown in graph and table form. W. H. Boynton

Iron blues in synthetic vehicles. W. Krumbhaar. *Bay Gum* (Detroit) **9**, No. 6, 8-10(1939); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 338(1939).—The modifications in manufg. methods required to produce the different com. grades of Prussian blues are described. George Ayers

Ink. E. St. John. *Inland Printer* Aug., **1939**, 49; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 360(1939).—A discussion of (1) the effect of foodstuffs, soaps, spices, etc., on inks, and (2) the use of synthetic resins and cellulose derivs. in photogravure inks. George Ayers

News inks. F. L. Watson. *Brit. Printer* **52**, No. 307, 44(1939); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 360(1939).—A review. George Ayers

The printing ink patents of the United States. International Association of Printing House Craftsmen. *Craftsmen's Research Bur.*, Tech. Paper No. **10**; *Rev. Current Lit. Paint, Colour, Varnish & Applied Ind.* **12**, 360(1939). —A review. George Ayers

Hardening of printed ink on the press. International 8
Association of Printing House Craftsmen. *Share Your Knowledge Rev.* June, **1939**, 15; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 360(1939).—A survey of U. S. patents. George Ayers

Causes of set-off. E. Coussement. *Chronique graphique* **14**, 4428(1939); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 359(1939).—Causes of set-off, such as highly glazed paper, inferior ink, faulty reduction of inks, faulty roller setting, and low temp. are discussed. George Ayers

An unusual type of set-off. Printing & Allied Trades Research Association. *Patra J.* **2**, No. 5, 225-8(1939); *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 360(1939).—A stain often appearing on the back of printed work and not produced by ordinary set-off or strike-through occurs with all drying-oil-contg. inks and is probably due to evolution of volatile matter from the oil. George Ayers

Drying oils and resins. Insolubilization of maleic glycol polyesters by additive polymerization. E. L. Kropa and T. F. Bradley. *Ind. Eng. Chem.* **31**, 1512–16(1939); cf. *C. A.* **32**, 6080[8].— Maleic glycol polyester (I), $(-CO-CH=CH-CO\cdot O\cdot CH_2\cdot CH_2\cdot O-)_x$, heated at 90° with 1/3 its wt. of vinyl acetate (II) formed an insol. gel in which the chains of I are believed to be linked at the double bonds through mols. of II in the same way as rubber is linked by S in vulcanization. The reaction is accelerated by the Hg arc, + Bz_2O_2. Me methacrylate reacted similarly, with development of various colors (Christiansen effect). Styrene (III) did not dissolve I but reacted with 10% of a mixed triethylene glycol polyester (IV) of maleic acid (V) and "Petrex" (the addn. product of terpene and V) in 13 days at 62° to form a hard, clear resin insol. in PhH. IV and $(CH_2=CH)_2C_6H_4$ thus act similarly upon III since both are polyfunctional (contain 2 or more active double bonds). Arnold M. Collins

Utilization of synthetic rubber in the production of drying oils. Kulikov. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 8, 43–53; *Khim. Referat. Zhur.* 2, No. 3, 118(1939).— Drying oils contained 5.7–8.4% of synthetic rubber, "siccative 630" and semidrying oils, cod-liver oil or linseed oil and 53.5–71.1% of white spirit. The thick pastes prepd. from these drying oils with ZnO, ocher, Fe_2O_3 and carbon black were dild. to paint consistency with "sunflower" drying oil (mixt. of sunflower-seed oil, prepd. castor oil and white spirit), or with synthetic or natural drying oil. The paints were tested for covering, drying properties, elasticity and hardness. The content of the film-forming substances in the paints with synthetic rubber was lower than in ordinary oil paints (6–30%). The paints prepd. with drying oils contg. synthetic rubber without natural drying oils or the sunflower-seed oil had a dull finish when dry. Paints with ZnO and most paints with ocher had good water-resistance. Less water-resistant were the Fe_2O_3 paints, and still less the carbon-black paints. On standing, the pastes prepd. with drying oils contg. synthetic rubber formed a rubberized layer on the surface. W. R. Henn

Tung-oil substitution. E. Melling. *Paint Manuf.* **9**, 347–50(1939). There are 3 main types of substitution, either partly or wholly as follows: (1) by resin or resin mixts., (2) by other oils, (3) by other materials, as chlorinated rubber. The type of substitute is dependent upon the outstanding property required of the finished product. In retaining drying speed resin substitute is suitable, but at the expense of flexibility, outside life and like characteristics. Combinations such as 100% phenolic resins and linseed oil, alkyd resin plus linseed oil-copal ester varnishes, the substitution of perilla, oiticica, dehydrated castor and fish oils for tung oil are discussed. None of these completely fulfills the properties of tung oil. It is necessary to formulate the medium for the particular job, note the primary characteristics wanted and formulate accordingly using mixts. of oils and resins till the most satisfactory product is found. Chlorinated rubber may replace the tung oil - 100% phenolic combination for producing an alkaliproof paint. W. H. Boynton

Ideal matt varnish. H. Courtney Bryson. *Paint Manuf.* **9**, 351–2(1939).- Fifteen properties in the order of their importance for an ideal matt varnish are listed. Matt finishes can be produced by the utilization of waxes, the use of certain org. compds. of Al, and by the incorporation of pigments with a refractive index roughly equal to that of the dry film. Particle size is important in the latter case. Advantages and disadvantages are given for each means of producing the matt finish. W. H. B.

Electrical heat for the modern varnish kettle. W. R. Beach. *Am. Ink Maker* **17**, No. 12, 20–1(1939). E. H.

The stability of the alkyd lacquers. A. A. Bolotin and M. N. Nasilova. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 5, 44–8; *Khim. Referat. Zhur.* 2, No. 2, 119(1939).—The lacquers consisted of 33% of phthalic anhydride, 17% of glycerol and 50% of linseed oil. As solvents there were used (singly and in mixts.) white spirit, solvent naphtha, turpentine and xylene; as driers, Pb-Mn and Pb-Mn-Co. Lacquers prepd. from phthalic anhydride, gycerol and linseed oil with different combinations of solvents and used in different proportions were tested for viscosity the day of prepn. and after 10, 20, 40 and 60 days. White spirit alone is unsatisfactory as solvent. Optimum results were obtained with solvent naphtha, with turpentine and with a mixt. of white spirit and solvent naphtha. Best thickening results were obtained from lacquers prepd. with Pb-Mn driers. Lacquers which did not contain driers did not change in viscosity for 2 months. W. R. Henn

Testing of polygraphic lacquers. B. I. Berezin. *Poligraf. Proizvodstvo* **1938**, No. 11, 33–4; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 359(1939).— Methods for the detn. of consistency, drying rate, impurities, gloss, hardness and elasticity of the film, penetration into the paper, etc., are included. George Ayers

Water absorbency of the alkyd air-dried and baked lacquers. A. A. Bolotin and M. N. Nasilova. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 5, 49–54; *Khim. Referat. Zhur.* 2, No. 2, 119(1939).—Lacquers (with or without driers) were spread on 2 glass plates one of which was dried at room temp. and the other at 100°. The films of the air-dried lacquers rapidly turned white in water and soon peeled off (except of the lacquers prepd. without driers). Only the baked lacquers were water-resistant. The character of the solvents and of the driers did not affect the water-resistance of either the baked or the air-dried lacquers. The most water-resistant lacquers were prepd with the fat acids of cottonseed oil. The optimum ratio of glycerol phthalate to the oil was 1·1. W. R. Henn

Fibrous lac. R. Bhattacharya and G. D. Heath *London Shellac Research Bur.*, Tech. Paper No. **18**, 14 pp. (1939).—B. and H. describe a process which produces a resin possessing a characteristic fibrous form. This consists of gelation of ammoniacal soln. of lac by HCHO. The gel, on washing with hot H_2O, gives an insol. and a sol. fraction, which are similar to hard and soft lac resins. The insol. resin has rapid "heat curing" property and gives solns. having higher viscosity than those obtained from ordinary lac or hard lac resins of corresponding concns. Data show that the best results are obtained by using a 20% soln. of lac in NH_4OH, approx. 3.2% by vol. of 40% HCHO soln. at 20° and a gelling time of 2 hrs. The films from fibrous lac are quick-drying and have good H_2O-resistance with a tendency to craze under severe conditions. This deficiency can be overcome by the use of suitable plasticizers. H. Marc

Nonwax floor finishes. I. Charles S. Glickman. *Soap* (Sanitary Products Sect.) **15**, No. 11, 90–2, 109(1939) —Nonwax floor finishes are characterized by high gloss, high water resistance, low slipperiness, high wearability and fairly low cost. Other qualities are discussed and comparisons made with water emulsion, paste and liquid polishes. II. *Ibid.* No. 12, 109, 111, 113, 127.—Nonwax floor finishes consist of natural resins or gums dissolved in hydrocarbon solvents. G. discusses spirit varnishes which are quick drying and of simple compn. Fifteen resins with their phys. characteristics, costs and solubilities are specified and general directions for manuf. are given. Four references. Henry H. Richardson

Studies on the constitution of the shellac complex. I. Interaction of tolyl iodochloride with shellac. M. Venugopalan, H. K. Sen and S. C. De. *Indian Lac Research Inst., Bull. No.* **33**, 14 pp.(1939).—Simultaneous substitution and oxidation reactions complicate the detn. of unsatn. in shellac by various halogen addn. reagents. A new reagent, formed by dissolving 0.05 mol. *p*-tolyl iodochloride (yellow crystals from passing Cl into *p*-iodotoluene dissolved in 5 parts of $CHCl_3$, filtering, washing with cold $CHCl_3$ and Et_2O, resp., and drying) in 250 cc. of $CHCl_3$ and then making up to 1 l. with glacial AcOH, gives results approx. similar to those obtained by the Wijs method. With shellac still closer correlation of the 2 methods is obtained after subtracting 10% (corresponding to about 1.4 in I value) from the results by the new method. The new reagent, upon standing, deteriorates somewhat more rapidly than does Wijs reagent. For detn. of I value by the new method, 25 cc. of HOAc and 5 cc. of $CHCl_3$ are added to 0.2 g. (or 10 cc. of a soln. of 4 g. made up to 200 cc. with $CHCl_3$-HOAc or HOAc) of substance

such as shellac, followed by 20 cc. of the *p*-tolyl iodochloride reagent. After standing for 1 hr. at 22 ± 1° in the dark, 10 cc. of 10% KI soln. is added and the excess I titrated with standard $Na_2S_2O_3$ soln. Iodine values of oleic acid, various shellac samples, linseed oil, Norwegian cod-liver oil, castor oil, olive oil, sesame oil, almond oil and rosin were detd. by both Wijs and *p*-tolyl iodochloride methods. Based on work with shellac, the I value increases with (1) time of absorption, (2) amt. of reagent used and (3) increase of temp., but decreases with increase in the amt. of sample used. Addn. of I in AcOH to the *p*-tolyl iodochloride reagent diminishes the time necessary for the detn. of I value. George Ayers

Protection of magnesium and its alloys. E. Barboni. *Journée ind.* (Paris) **1939**; *Rev. Current Lit. Paint, Colour, Varnish & Allied Ind.* **12**, 401(1939).—No paint will adhere to the metal unless the latter is first treated chemically (immersion in KNO_3 or $K_2Cr_2O_7$ soln.) or electrolytically. The second and third coats must not be of cellulose materials. George Ayers

Extg. grape seed [drying oil] (Gavrilenko) **27**. Constancy of chem. properties of tung tree (Taran) **11D**. Elec drying oven for lacquers liable to detonate (Lohausen, Schumann) **4**.

Norme italiane per il controllo degli olii per Vernici. 1st ed. Milan: R. Stazione Sperimentale per l'Industria degli Olii e dei grassi. 257 pp. No price stated. Reviewed in *Chem. Trade J.* **105**, 334(1939).

Use of copper paint on surfaces such as those of metal. Harry A. Sweeney and Leo D. Pangborn (to National Copper Paint Co.). U. S. 2,176,597, Oct. 17. A process employed involves applying to the surface to be coated a primer which includes in its compn. Si which has been treated in an oven at a temp. of about 2040°, a flatting agent such as celite adapted to give bulk so that the Si will settle over the surface and a varnish having a high absorptive factor for H and adapted to absorb excess H from the Si, together with light naphtha as a solvent and a small quantity of an anticoagulant such as "Dipentine" and then causing the primer to dry with microscopic projections, and then applying a paint contg. amorphous Cu in a varnish together with Ca linoleate as a suspension agent, and a drier including Co, Pb and a hydrocarbon solvent such as naphtha.

Calcimine. Herman A. Scholz and Alexander Adams (to United States Gypsum Co.). U. S. 2,177,154, Oct. 24. A dry calcimine or distemper paint compn. contains as its main pigment powd. gypsum, a water-sol. adhesive such as glue, and only sufficient of an alk.-reacting material, such as NaOAc, to overcome the acidity of the compn. so that when it is gaged with water a compn. is formed having a pH of 7.0–8.5, the gypsum having a high opacity and hiding power.

Blended pigment. Marion L. Hanahan and Rodolphe V. Gagnon (to E. I. du Pont de Nemours & Co.). U. S. 2,177,250, Oct. 24. $CaSO_4$ contg. less combined water than the dihydrate is subjected to hydration in the presence of an aq. suspension of a Ti pigment such as TiO_2 and the mixt. is concurrently subjected to a mech. shearing action, and the product thus obtained is dehydrated within about 30 min. from the completion of the hydration and sharing treatment. U. S. 2,177,251 relates to a similar process in which an aq. suspension of ZnS is used instead of the Ti pigment.

Composite pigments. Hugh V. Alessandroni (to National Lead Co.). U. S. 2,176,875, Oct. 24. Separately dispersed suspensions of pigments such as TiO_2 and $BaSO_4$ are prepd. by means of dispersing agents which are not antipathetic to each other, such as Na silicate, and the suspensions are mixed together and the dispersed pigments are coflocculated by a coagulating agent such as $MgSO_4$. Various examples are given. U. S. 2,176,876 relates to the manuf. of a composite pigment formed of ZnS and another pigment such as $BaSO_4$ by a generally similar method.

U. S. 2,176,877 relates to a similar process except that antipathetic dispersing agents such as Na silicate and Pb chloride are used in the initially prepd. sep. pigment dispersions so that coflocculation takes place when they are mixed. Cf. *C. A.* **34**, 2764.

Pigment dispersions. Paul E. Marling and Charles A. Thomas (to Monsanto Chemical Co.). U. S. 2,176,219, Oct. 17. A dispersion in concd. paste form suitable for use in prepg. paints or varnishes consists of a pigment such as ZnO or white lead or TiO_2 intimately mixed with a soln. in a volatile solvent, such as petroleum naphtha, of the unsatd. petroleum-naphtha-sol. hydrocarbon resin obtained by polymerizing a cracked petroleum distillate fraction rich in diolefins under the influence of a Friedel-Crafts catalyst.

Molybdenum orange. Arthur Linz and Lynn W. Coffer (to Climax Molybdenum Co.). U. S. 2,176,819, Oct. 17. A process for the production of molybdenum orange involves mixing a soln. of a sol. chromic acid salt such as $Na_2Cr_2O_7$ and a sol. molybdic acid salt such as Na_2MoO_4 with a soln. of a sol. Pb salt such as $Pb(NO_3)_2$ to form a ppt. at pH 3.0–5.0 and reducing the pH of the mixt. contg. the ppt. to 2.5–3.0 for the development of the color in the ppt.

Stabilizing pigment sulfates and carbonates of alkaline earth metals. Roy W. Sullivan (to E. I. du Pont de Nemours & Co.). U. S. 2,177,269, Oct. 24. Compds. such as anhydrite are stabilized against increase in particle size by admixt. with 10% or less (suitably about 0.1–1%) of a water-sol. glycolate such as an alkali metal starch glycolate.

Compositions suitable for use as pigments, insecticides, etc. Arthur B. Cummins (to Johns-Manville Corp.). U. S. 2,177,197, Oct. 24. An intimate mixt. of finely divided diatomaceous earth and an oxide (or compd. such as $Pb(NO_3)_2$ reactive at the calcination temp.) of Pb, Zn, Bi, Cd, Cr, As, Sb, Mo, Ti, V, Ag or Hg in an amt. 1–40% that of the diatomaceous earth is heated to about 815–1040° to form a complex product contg. a sufficient amt. of unreacted diatomaceous earth to serve as an extender together with a reaction product of the heavy metal compd. and silica of the diatomaceous earth, without eliminating the characteristic structure of the diatomaceous earth.

Polymerizing China wood oil. Solomon Caplan (to Harvel Research Corp.). U. S. 2,176,058, Oct. 17. Diethyl sulfate (suitably in a proportion of about 5–10%) is dissolved in China wood oil then heated to about 105° to effect desired polymerization, as *for use in varnishes*, molded products, etc. (the diethyl sulfate serving to promote polymerization).

Polymerizing cashew nutshell liquid. Solomon Caplan (to Harvel Corp.). U. S. 2,176,059, Oct. 17. About 2% or more of diethyl sulfate or other mono- or di-alkyl sulfate which may contain H_2SO_4 is dissolved in cashew nutshell liquid, the soln. is heated (suitably to about 160°) to effect reaction of the soln. with the metals naturally present in the cashew nutshell liquid and ppt. salts of the metals, and the ppt. is removed. A polymerized product may be obtained which is suitable for use in making varnishes, etc.

Treating hydrocarbons from rosin, etc., to produce products for use in paints, etc. Edwin R. Littmann (to Hercules Powder Co.). U. S. 2,177,530, Oct. 24. A method of treating a hydrocarbon derived by decarboxylation of rosin, partially hydrogenated rosin, rosin acids or partially hydrogenated rosin acids involves bringing the hydrocarbon in the liquid phase into contact with an active hydrogenation catalyst under conditions of reaction adapted to produce an intra- and inter-mol. rearrangement of H atoms in the hydrocarbon and in the absence of added substances capable of reducing the unsatn. of the hydrocarbon. Various examples with details are given.

Nitrocellulose and other coating compositions. Carleton Ellis (to Ellis-Foster Co.). U. S. 2,177,418, Oct. 24. A nitrocellulose of low viscosity is used with fatty oil-acid phthalic glyceride resins, to form compns. which are suitable for coating metals, etc.

Coating materials containing phenolic condensation

products. Siegfried Kohn (to Resinous Products & Chemical Co.). U. S. 2,169,361, Aug. 15. Products suitable for use as varnishes are formed contg. an oil-sol. condensation product obtainable by condensing less than 0.75 mol. of HCHO and one mol. of a complex cryst. phenol, such as dihydroxydiphenyl dimethylmethane, obtainable by the condensation of a phenol and a ketone, and these products may also be used in admixt. with a natural resin, etc.

Liquid coating compositions containing soaps. Theodore F. Bradley (to American Cyanamid Co.). U. S. 2,169,577, Aug. 15. An air-drying, coherent film-forming coating compn. suitable for use on textiles, paper, etc. comprises a soln. including a fusible, hydrocarbon-sol., unoxidized and O-convertible soap contg. in chem. combination a metal such as Al or Fe that can exist in a state of multivalency of at least 3 and a soap-forming fatty acid, such as linseed fatty acids, contg. at least 2 C-to-C double bonds in the mol., a hydrocarbon solvent for the soap such as turpentine, and a catalytic oxidation promoter, the soap being present as the major film-forming constituent, and films formed from the soln. being convertible to substantially insol., substantially infusible varnish-like films through exposure to air.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The thermostability of some fats. E. Glimm, H. Wittmeyer and W. Jahn-Held. *Z. Untersuch. Lebensm.* **78**, 285-93(1939). - Data on hydrolysis of beef tallow, lard, coconut oil, palm-kernel oil, sesame oil, peanut oil, olive oil and trioleins at temps. between 60 and 120° for time intervals of 7 days are presented graphically. The degree of splitting by warming was independent of the original content of free fat acids but rose with increases in temp. and time of heating. No appreciable splitting occurred in beef tallow or lard at temps. up to 60°. With vegetable oils it was found that each showed a crit. temp. at and above which an appreciable increase in splitting occurred in 3 days. These crit. temps. were: coconut oil 100°, palm-kernel oil 90°, olive oil 90°, peanut oil 80°, soybean oil 80° and sesame oil 75°. M. M. Piskur

Hydrogenation of mixed oils. Antonio I. de Leon and Felipe T. Agdeppa. *Philippine Agr.* **28**, 225-42(1939).—Coconut, pilinut (*Canarium ovatum* Engl.), peanut (*Arachis hypogaea* Linn.) and kapok-seed (*Ceiba pentandra* Linn.) oils were hydrogenated, after treatment with kieselguhr and Na_2SO_4, at 180-90° by use of the Raney Catalyst Powder previously activated with NaOH. This catalyst contained 52.63% Ni. I no. and m. ps. were detd. every 2 hrs. during each hydrogenation. Hydrogenation of coconut oil for 20 hrs. with 3% of Ni reduced the I value from 6.07 to 3.83, when 1% of Ni was used a final I value of 2.90 and a m. p. of 29-35° were obtained. Similar hydrogenation of pilinut oil for 20 hrs. with 1, 2 and 3% of Ni reduced the I value from 60.04 to 19.84, 14.76 and 3.13, resp., with m. ps. of 50-56, 53-60.5 and 60-69.5°, resp. Similar hydrogenation of peanut oil for 20 hrs. reduced the I value from 95.46 to 35.89, 26.33 and 16.40, resp., with m. ps. of 37-42, 46-53 and 55-62°, resp. Similar hydrogenation of kapok-seed oil for 20 hrs. reduced the I value from 93.20 to 49.14, 45.26 and 25.31, resp., with m. ps. below room temp., 31-39 and 49-57°, resp. Similar hydrogenation of a 1:1 mixt. of pilinut and coconut oils for 20 hrs. reduced the I value from 33.15 to 12.80, 9.80 and 6.70, resp., with m. ps. of 42-50, 46-54 and 50-57°, resp. In a 1:2 mixt. the initial I value of 24.06 was reduced to 10.66, 8.08 and 5.74, resp., with m. ps. of about room temp., 38-44 and 42-48°, resp. In a 1:3 mixt. the initial I value of 19.14 was reduced to 7.39 when 2% of Ni was used, and 5.26 with 3% with m. ps. below room temp. and 33-39°, resp. In a 1:4 mixt. with 3% Ni the initial I value of 16.84 was reduced to 5.13 and a product 40% solid was obtained. Hydrogenation of a 1:1 mixt. of peanut and coconut oil with 1, 2 and 3% of Ni reduced the I value from 50.60 to 20.82, 15.56 and 10.12, resp., with m. ps. below room temp., 41-50, and 47-54°, resp. In a 1:2 mixt. the I value was reduced from 33.20 to 11.99 with 2% of Ni and to 8.03 with 3% with m. ps. below room temp. and 40-47°, resp. In a 1:3 mixt. the I value was reduced from 27.12 to 6.97 and a soft solid obtained with 3% of Ni. Hydrogenation of a 1:1 mixt. of kapok and coconut oils for 20 hrs. with 3 and 4% of Ni reduced the I value from 49.13 to 21.04 and 14.11, resp., and gave a soft solid product and one having a m. p. of 43-50°. In a 1:2 mixt. with 4% Ni the I value was reduced in 20 hrs. from 32.14 to 10.23 and a m. p. of 35-42° obtained. Increasing the amt. of catalyst results in a decrease in I value and an increase in m. p. of the product. Raney Catalyst Powder is simpler to use and gives about the same results as Ni catalyst from Ni carbonate. Mixts. of equal parts of pilinut and coconut oils gave good products on hydrogenation for 6 hrs. with 3% Ni, for 8 hrs. with 2% of Ni or for 12 hrs. with 1% of Ni. Mixts. contg. 1 part of pilinut to 2 parts of coconut oil gave good products after 10 hrs. with 3% of Ni or after 18 hrs. with 2% of Ni. Suitable products were obtained from 1:1 mixts. of peanut and coconut oils after 6 hrs. with 3% of Ni or 16 hrs. with 2% of Ni; 1:2 mixts. required 14 hrs. with 3% of Ni. Mixts. of kapok and coconut oils required 10 hrs. with 4% of Ni. Products suitable for the *margarine industry* can be prepd. by adding coconut oil to the hydrogenated mixt. 9 references. Colin W. Whittaker

Drying bottles for processed vegetable oils. I. Berg. *Masloboino Zhirovoe Delo* **15**, No. 3, 28-9(1939).—Illustrated description of the construction and operation of an improved drying cabinet, with mech. conveyor, for drying bottles before filling them with oil. Previous driers were inefficient, either leaving liquid water in the bottles or permitting condensation after drying and cooling, so that the oil was contaminated with water when bottled. Julian F. Smith

Continuous oil-refining process. I. Tovbin. *Masloboino Zhirovoe Delo* **15**, No. 3, 5-7(1939).—The Sharples supercentrifuge system for neutralizing oils, the Foster-Wheeler steam deodorizer (with Dowtherm as heat carrier) and a continuous-vacuum filtration system have been combined into a cycle of operations whereby an oil or fat can be continuously neutralized, deodorized and clarified. The output is considerably greater than in batch operation. Julian F. Smith

Anderson expeller RB. K. Leont'evskii and I. Morozov. *Masloboino Zhirovoe Delo* **15**, No. 2, 34-5(1939).—The Anderson RB type expeller has been applied to the processing of copra, palm kernels and cottonseed. The machine is illustrated and its operation for these purposes is described. Julian F. Smith

Achieving a lower content of hulls in oil-seed cake. V. Sadomskii and L. Rodina. *Masloboino Zhirovoe Delo* **15**, No. 2, 3-5(1939).—In a study of methods for obtaining sunflower-seed cake with min. hull content the customary procedure for prepg. and processing seed pulp was compared with 2 modifications; in one the seed pulp was steamed under 10 atm. pressure before the final heating, in the other it was steamed at 5 atm. in admixt. with condensate. Some modifications in mech. huller operation are also described and illustrated. Tabulated data show the moisture content and oil content of the seed cake produced by the customary and modified procedures. Julian F. Smith

The Kudryavtsev-Vasil'ev mill for processing sunflower seed. N. Kudryavtsev. *Masloboino Zhirovoe Delo* **15**, No. 2, 38-40(1939).—Illustrated description of construction and operation. Julian F. Smith

Pressing sunflower-seed pulp without a cloth. S. Kucherov. *Masloboino Zhirovoe Delo* **15**, No. 2, 9-12(1939).—Pressing sunflower-seed pulp without a press

cloth lowers press efficiency by 5–10% but gives a better appearing cake, clean and free from shreds of wool. A procedure in which the pressure was raised to the first stage in 3 min., then to the final stage in 3 min., proved to be too rapid. More time is needed for attaining the final pressure (300 atm.). Iron and wood frames for pressing without a press cloth are described and illustrated.
Julian F. Smith

Extracting grape seed. I. Gavrilenko. *Masloboino Zhirovoe Delo* **15**, No. 3, 3-5(1939).—Grape seed can be successfully extd. with gasoline in a battery of extractors. For best quality and yield of oil the seed must be clean (it can be freed from skins and dirt in a Saturnia machine) and should be dried to 8–9% moisture while fresh, before mold growth can set in. The yield of oil from 100 tons grape seed was 10.87 tons; unavoidable loss of oil, 0.12 ton. The I no. of the oil was 132.8, indicating the possibility of use as a *drying oil* in paint manuf. The extn. residue may be used in *stock feed* or in making *coffee substitutes*.
Julian F. Smith

Commercial value of Asclepias syriaca. G. P. Stepanov. *Caoutchouc and Rubber* (U. S. S. R.) **1939**, No. 9, 10-3.—The seeds of *Asclepias syriaca* contain 17% oil having an acid no. of 94.75 (after storage) and 0.7% unsaponifiable matter. The oil has 37.49% protein and 8.88% ash. The oil may be used in the manuf. of liquid soap, lipid siccatives, and solid fats by hydrogenation.
B. Z. Kamich

The development of sulfonated oils and fatty alcohols. Alfred Wende. *Soc. Chem. Ind. Victoria, Proc.* **39**, 189-98(1939).
E. H.

Determining hydrocarbons in unsaponifiable. J. Grossfeld. *Z. Untersuch. Lebensm.* **78**, 273-85(1939).—It had been observed (cf. *C. A.* **33**, 3012[1]) that petr. ether quickly extr. the hydrocarbons from alc. soap solns., while the sterols are extd. less easily. This led to the development of new characteristics for the unsaponifiable matter of fats. The weighed unsaponifiable matter of a fat, 5 g. of a fat acid, 20 cc. 96% alc., and 3 cc. KOH (sp. gr. 1.5) are refluxed 5 min., cooled, 50 cc. petr. ether (b. 60–70°) and 1 cc. of H_2O are added, and the charge is stoppered and vigorously shaken. The residue from 25 cc. of solvent is dried. If palmitic acid was the fat acid used the characteristic is called "palmitate hydrocarbon value" (I) which equals 100 (50/25) (wt. of residue/wt. of unsaponifiable). With use of oleic acid in the detn. the characteristic is called "oleate hydrocarbon value" (II). Results on detg. I and II, resp., on some compds. were: paraffin 109, 107, sterols 26, 27, cetyl alc. 39, 43 and "Boeson trennwax" 7.7, 7.9. The values for paraffin and paraffin oil as well as those for cholesterol and phytosterol were practically alike. The relative amts. of sterols and hydrocarbons in mixtures can be calcd. with the use of this characteristic and the above data.
M. M. Piskur

Oleosols of soaps. I. Solution of soaps in hydrocarbons. G. E. Levant and E. L. Al'perovich. *Colloid J.* (U. S. S. R.) **5**, 493-500(1939).—Metal stearates were prepd. from K stearate and a convenient metal salt, and were not analyzed. They were shaken for 2 hrs. with a paraffin oil, and the amt. dissolved was detd. It increased with rising temp. (25-140°). Stearates of Ca, Sr, Ba, Cd, Al, Bi, Mn, Fe, Co, Ni and Cu were used.
J. J. Bikerman

Synthetic fats from petroleum suitable for grease making (Burwell, Camelford) **22**. Adsorbent material for treating vegetable oils (U. S. pat. 2,176,851) **18**.

Distillation of fat acids, oils, etc. Alan P. Lee U. S. 2,177,664, Oct. 31. App. is described, and a process for distn. with avoidance of decompn. which involves atomizing the material at atm. or higher pressure with not less than about 5 times its own vol. of inert gas to form an atomized mist consisting of a continuous phase of inert gas contg. and surrounding a discontinuous phase of liquid, heating the atomized mist as such in a continuous tubular structure to a temp. below the initial vaporization temp. of the liquid at the pressure of the heating, but which temp. is higher than the initial vaporization temp. of the liquid at a subsequent subatm. distg. pressure and is within the normal temp. range of incipient decompn. of the liquid if subjected to flow as a liquid stream through a heated tube, expanding the heated atomized mist through suitable control means into a distg. zone of subatm. pressure and passing inert gas into the distd. zone to promote vaporization of liquid from the atomized mist.

Soap. Helen M. Cranor. U. S. 2,177,055, Oct. 24. A toilet soap in cake form, of smooth texture, good lathering properties and deodorant action contains $NaHCO_3$ 10-30% (less than would cause crumbling of the compn.) and an approx. neutral soap 90-70%.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Fertilizer requirements of sugar cane in Egypt (Rosenfeld) 15. Paints [for sugar factories] for exposure in Cuba Poland) **26**. Compn. of colloids of diffusion sap of beet (Smonova) **2**. Investigations on sugar cane on saline soils (Nagata, Sasaki) **15**.

Swelling starch nonlumping with cold water. Helmut Schorn and Carl V. Daumas (to N.-V. "Agratherm"). U. S. 2,177,378, Oct. 24. App. is described, and a method which involves moistening starch, comminuting and sieving it, subjecting the resulting starch particles to a plurality of jets of superheated steam having a temp. of 200–500° for a short time to diminish the sp. wt. of some of the starch particles and to sep. by the force of the jets those particles the sp. wt. of which has been diminished.

29—LEATHER AND GLUE

HENRY B. MERRILL

Unhairing with the fruits of Solanum campylacanthum Hochst of the Italian East Africa. Preliminary note. Rino Airoldi. *Atti ufficiale assoc. ital. chim. tec. conciaria* **2**, 251-65(1939).—Fruits of *S. campylacanthum* Hochst contain seeds 9-11.6, H_2O 78-80, dry matter 8.4-13%, pH of the juice 5.4, fat from the seeds (extn. with Et_2O) 15.1, tannins (filter method; pyrocatechuic) 2.48, ash (calcd. on dry matter without seeds) 4.66, reducing sugars 4.85, total sugars 13.61, N-contg. matter (N 6.25) 12.89, crude cellulose (König method) 19.10%. The acidity of the fruits is due principally to malic acid. Unhairing expts. were made on sheep skins simultaneously with a paste of *S. campylacanthum* (15% of dry matter) and with CaO and Na_2S normal unhairing mixt., and the unhaired samples were tanned with sumac. The leathers obtained were nearly identical in their characters, but the wool sepd. from the skins treated with the fruits was slightly brown. The unhairing action is attributed to the proteases contained in the fruits; rH was 15.2 (at pH 5.56 and 25°); these proteases do not sensibly deteriorate collagen and wool proteins.
G. A. Bravo

Preparation of analytical solutions of tanning extracts from large quantities of the solid extract. V. A. Zotov and S. S. Martynova. *Kozhevenno-Obuvnaya Prom. U. S. S. R.* **12**, No. 4, 55(1939); *Chem. Zentr.* **1939**, II, 2604.—In dissolving 100–200 g. of tanning ext. and diln.

to 0.5 to 1 l., the soln. becomes turbid owing to the pptn. of phlobaphenes. It is recommended to dissolve 80 g. of the ext. in 5 vols. of hot water and to boil the mixt. on a water bath for 15 min. to complete solution, to transfer to a 2-l. measuring flask cooling on the water bath to 20°, to fill to the mark with cold water, to mix thoroughly, to transfer 400 cc. to a second flask and to dil. with boiling water to 2 l. The turbidity is thus eliminated. A. A. Boehtlingk 1

The tanning value as a function of the concentration of tanning extract and of the water content of the pelt. Emilio Durio. *Atti ufficiali assoc. ital. chim. tec. conciaria* **2**, 201-7; *Cuir tech.* **28**, 214-15(1939).—Expts. were made with hide powder and chestnut, quebracho and mimosa exts. The max. combination of tannin occurred in the solns. contg. 20% of ext., about 5°Bé., and with pelts of an initial moisture content of 75% or greater. The highest degree of tannage was given by freshly prepd. chestnut ext. Old exts. partially lose their tanning power owing to acid fermentation. G. A. Bravo 2 3

Further development of the production of synthetic tannins. Ya. P. Berkman. *Kozhevenno-Obuvnaya Prom.* **1938**, No. 7, 26-7; *Khim. Referat. Zhur.* **2**, No. 2, 129-30 (1939); cf. *C. A.* **33**, 6640[9], 6641[3].—A complete assortment of synthetic tannins of the light type can be obtained only by the use of phenols. Phenols in combination with hydrocarbons are especially valuable. The sulfite cellulose exts. can be used as starting raw materials for the heavy synthetic tannins. The tannins obtained from the products of condensation of the polyphenols with aldehydes are very similar to the plant tannins, but their high cost hinders their development as synthetic tannins of the heavy type. W. R. Henn 4

Soluble and insoluble matters in tanning sole leather. Cesare Schiaparelli. *Atti ufficiali assoc. ital. chim. tec. conciaria* **2**, 193-200(1939).—The less-sol. tannins and the insol. matter contained in the tanning exts. deposit at lower temps. and clog the pores of the skins; the absorption of this sparingly sol. matter occurs only at 28-30°. The insol. matter in the tanning exts. can be detd. by a sedimentation method (e. g., Kubelka method); the official (filter-candle) method gives high results. In the preliminary tanning process the exts. used should give little sediment. G. A. Bravo 5 6

A new type of silica tannage. Alexander Rose. *Can. J. Research* **17**, B, 385-9(1939).—Silica tannage, usually in combination with other methods, has been extensively investigated, but no process in which Si compds. were the principal agent has reached the com. stage. Et and Me orthosilicate possess a marked tanning action when hydrolyzed in dehydrated or pretanned pelt. Details of the prepn. of silica-tanned leather, analyses and hydrothermal behavior of the resulting material, and significance of the new method of tannage are discussed. J. W. Shipley 7

Pigments for leather. Michele Fiorenza. *Atti ufficiali assoc. ital. chim. tec. conciaria* **2**, 229-35(1939).—Insol. coloring matters for the prepn. of leather pigments may contain: (1) support, (2) solvent, (3) plasticizer, (4) coloring matter. Modern pigments for leather are: (white) TiO_2, ZnO, lithopone, Sb whites; (yellow and orange) Pb and Zn chromates, CdS; (brown) Fe oxides; (red) CdS, Fe oxides and insol. Ca and Ba derivs. of azo dyes; (blue) anthraquinone or indigo compds. and Cu derivs. of phthalocyanines. G. A. Bravo

Rapid determination of fat in leather. N. P. Kostin, B. N. Rybakov and P. K. Isaev. *Kozhevenno-Obuvnaya Prom. S. S. S. R.* **12**, No. 4, 56(1939); *Chem. Zentr.* **1939, II**, 2604.—The method proposed by Wislicenus in 1920 (cf. *C. A.* **15**, 380) for the analysis of coal, wood, etc., is recommended for the detn. of fat in leather. The sample is placed in a flask equipped with a reflux condenser through which a thread is passed only at the beginning of the boiling of the ether. The thread is removed after the end of the boiling and is rinsed with the condensate passing through the condenser. The "boiling" time is limited to 10 min. and the "rinsing" time to 15 min. The results agree satisfactorily with those of the Soxhlet method. A. A. Boehtlingk

Analyses of sole leather. IV. Bohemian and Danish. Vittorio Casaburi. *Boll. staz. sper. ind. pelli mat. concianti Napoli* **17**, 139-44(1939); cf. *C. A.* **33**, 6086[1].—By the method already described, 2 Bohemian leathers (obtained from salted hides, with pine-bark ext. tanning) and 1 Danish (from refrigerated hides, tanned by the ordinary quebracho process) were examd. The values obtained in the analyses are normal, but the middle layers of Danish leather appear to be more thoroughly tanned than the grain. G. A. Bravo

Waterproofing of fur skins. Use, detection and determination of formaldehyde in fur, hair and wool. Urbain J. Thuau and David Lisser. *Cuir tech.* **28**, 212-13 (1939).—Furs or hairs, e. g., wool of sheep skins, are waterproofed with CH_2O, acrolein or a compd. that produces CH_2O on heating, such as trioxymethylene, formaldehyde bisulfite or hexamethylenetetramine. The impregnated skins after some hrs. are hot-pressed or ironed at temps. above 100°. Hairs of calf, cow or rabbit skins are previously partially hydrolyzed. To det. CH_2O, 1-2 g. of the shaved hairs are boiled in a flask with 100 cc. 15% HCl with replacement of drop by drop by fresh acid of the liquid distd. off until the vol. of the distillate amounts to about 200 cc.; then the distn. is continued nearly to dryness. CH_2O can be detected by phenylhydrazine and $K_4Fe(CN)_6$. For the detn. there are added to the distillate 25 cc. 0.1 *N* iodine and concd. NaOH until the color of the liquid becomes light yellow. After cooling the excess I is titrated with a 0.1 *N* $Na_2S_2O_3$ after acidulation with HCl. George Nachod 8

Lubricating skins and leather. Joseph G. Niedercorn (to American Cyanamid Co.). U. S. 2,176,434, Oct. 17. The material is impregnated with a lubricant contg. jojoba seed oil or sulfonated jojoba seed oil.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Technical application of Buna in the chemical industry. II. Vulcanized rubber from Buna. H. Roelig. *Chem. Fabrik* **1939**, 481-2; cf. *C. A.* **32**, 6905[4].—The phys. properties of hard rubber made from Buna-S and Zahlenbuna with that made from natural rubber are practically alike. But when protective coatings are applied, certain extra precautions are necessary with Buna rubber, which are outlined. Buna is as resistant as natural rubber to H_2SO_4 (up to 50%), to all concns. of HCl, to NaOH and KOH solns. and to AcOH and salt solns., but less resistant to Cl gas and solns. and to HNO_3. Buna is superior with C_6H_6, CCl_4, etc., and in heat aging. J. H. Moore 9

The state of aggregation of rubber and of substances with rubber-like extensibility. Kurt H. Meyer. *Chem. Rev.* **25**, 137-49(1939).—A review. Louise Kelley

Chromatography of rubber solutions. Giorgio R. Levi and Gian P. Cajelli. *Rev. brasil. chim.* (São Paulo) **8**, 119-21, 161-7(1939).—See *C. A.* **33**, 9043[6]. L. E. G.

Utilization of synthetic rubber in production of drying oils (Kulikov) **26**. Method for prepg. rubber (without use of gasoline applied to prepn. of artificial leather (Aizenshtein) **13**. Impregnation with rubber of raincoat fabrics (Kurialt) **25**.

Apparatus for molding gas-expanded rubber products. Dudley Roberts (to Rubatex Products, Inc.). U. S. 2,176,945, Oct. 24. Various structural, mech. and operative details.

CHEMICAL ABSTRACTS

Vol. 34 MARCH 10, 1940 No. 5

1—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

Vapor-proof laboratory stirrer. Geo. Calingaert. *Ind. Eng. Chem., Anal. Ed.* **12**, 51(1940).—A flask stirrer is described using oilless bearings as guides and seals. H. G. Bowlus

Simple holding devices for laboratory glassware. A. H. Waychoff. *Products Finishing* **4**, No. 3, 54–5(1939).—A device for holding flasks, beakers, retorts, etc., can be made by splitting a hollow rubber ball in half and fastening each half to a table or shelf by means of a small nail or tack. By using balls of various sizes different pieces of glassware can be protected against tipping, spilling and breaking. A device for holding and protecting thermometers, hydrometers, pipets, etc., against breakage can be made from rubber hose. One end of the hose is cut in four segments of $1^1/_2$" length. These segments are spread apart and nailed to a table or board. A rubber stopper is placed on the bottom at the center so as to cushion the piece of glassware when it is dropped into the holder. Leopold Scheflan

Simple valve for use in laboratory apparatus. G. P. Gibson. *J. Soc. Chem. Ind.* **58**, 317–19(1939).—A glass needle valve having grooves in the stem and seat is used to regulate vapor flow or liquid take-off in distn. heads. H. G. Bowlus

Repair and construction of laboratory glassware. Joseph J. Sullivan. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 22–6(1939).—Certain fundamental operations in glass working are described and literature references are given. Leopold Scheflan

An improved test tube rack. Robert F. Ervin. *J. Lab. Clin. Med.* **25**, 320–2(1939).—A zigzag bar is supported at each end by uprights from a flat base and P bronze coil springs, securely fastened at each end, run down each side through holes in the apex of each V in the zigzag bar. The advantages are simplicity of design, ease of use, sturdiness of construction, and economy of space. Test tubes are held so firmly that the entire rack can be shaken without rattle or danger of slipping, and contents of all tubes are visible at the same time without removal from rack. Howard W. Robinson

Best pipe bending practice for the chemical plant. W. F. Schaphorst. *News Ed. (Am Chem. Soc.)* **18**, 48 (1940).—Filling pipes with sand, resin, pitch, rosin, paraffin wax, lead, Babbitt, etc. and then bending at a suitable temp. is described; the use of mech. devices for pipe bending is recommended. W. C. Ebaugh

Fundamental relationships in the design of cooling towers. G. Russell Nance. *Trans. Am. Soc. Mech. Engrs.* **61**, 721–5(1939).—Math. George Ayers

Progress in the field of technical plant heavy apparatus. VI. **Evaporators.** Bruno Waeser. *Chem. Fabrik* **1939**, 509–12; cf. *C. A.* **33**, 7149[3].—A chronological review of 245 papers and patents between 1933 and May 15, 1939, with over 270 references. J. H. Moore

An opacimeter used in chemical analysis. Ralph M. Evans and Geo. P. Silberstein. *J. Soc. Motion Picture Engrs.* **32**, 321–4(1939).—The opacimeter is an optical instrument designed to measure the light transmission of a colored or turbid soln. A Loewenthal Photronic type light-sensitive cell connected to a microammeter is used to measure the intensity of the light transmitted by the soln. under test. The light intensity falling on the sensitive cell is kept within a fixed range by varying the distance of the cell from the light source. The instrument is arranged so that a 30-cc. test tube or a 300-cc. Kohle flask may contain the reaction mixt. The results of analyses are detd. from calibration curves prepd. from known solns. Authors

New apparatus for qualitative semimicroanalysis. H. H. Barber. *Ind. Eng. Chem., Anal. Ed.* **12**, 58–60 (1940).—Test tubes, funnel, pressure filter tube, filter stick, vacuum-pressure bulb, and hot water bath are described and their use is illustrated by a method for the qual. semimicroanalysis of Group II. H. G. B.

A new device for determining carbon dioxide in the air. Seizi Miyamoto. *Japan. J. Exptl. Med.* **17**, 407–12(1939)(in English).—A modified app. is described which ensures greater accuracy in the vol. of air introduced. Diagrams and tables accompany the article. C. J.

Cleaning of air and gas by thermal repulsion. Samuel C. Blacktin. *J. Soc. Chem. Ind.* **58**, 334–8(1939).—The effect of heated solid bodies of rod form in producing at normal pressure a dust-free region around them is termed a radiometer action. C. conducted expts. testing various sources of heat and different types of dust-repelling app. Elec. heating (by conduction) and hot-water heating gave comparable results. A peripheral hot-wire repulsor was developed and served well as a dust repellor. In an electrically heated app., with air originally contg. at 18.4° 90,880 dust particles per cc., the contents were at 38.5° 52,000, at 55.0° 25,760, at 74° 17,080 and at 85.3° 3200 particles. An app. using hot-liquid heating gave with air originally contg. at 14° 56,000 particles per cc., at 29° 17,100, at 44° 4300, at 55° 3100 and at 81° "nil" particles per cc. H. E. Messmore

A portable self-powered suction apparatus for collecting air samples. Harold W. Ruf and Wm. Z. Fluck. *Wis. State Board Health Bull.* **6**, No. 8, 19–21(1937); *U. S. Pub. Health Eng. Abstracts* **18**, AC, 4 (Oct. 22, 1938).—An app. is described. C. R. Fellers

Theory of gas compression and circulation. D. M. Newitt. *Trans. Inst. Chem. Engrs.* (London) Advance copy, Dec. 12, **1939**, 16 pp.—A review. For medium and high pressures, N. shows how to arrange interstage pressures and temps. to divide the work of compression fairly evenly between stages, with small differences in max. interstage temps., using the temp.-entropy diagram. Fourteen figures and 52 equations. R. W. Higbie

Mechanical calculations for high-pressure apparatus. V. I. Sokolov. *Khim. Mashinostroenie* **1938**, No. 2, 14–18; *Khim. Referat. Zhur.* **2**, No. 1, 122–3(1939).—A formula is derived for the calcn. of app. under pressure $R = r/\sqrt{(\sigma_g - 1.73p)/\sigma_g}$, where σ_g is the safe working stress, p the pressure, R and r are the external and internal radii of the cylinder. For pressures close to $\sigma_g/1.73$ the formula does not apply, since R then approaches ∞. The expression in a more convenient form is $R = r(2.31\ \sigma_g + p)/(2.31\sigma_g - p)$. A general form which can be used under any pressure is $R = (r/\omega)(e^m)$, where m is related to the pressure p and to the limit of plastic flow σ_0 through the equation $m = [(p\sqrt{3})/2\sigma_0] - 0.5 + \omega^2/2$, and ω depends on the margin of strength n and is expressed by $\omega = \sqrt{(1 + 1/n)(0.5)} - \sqrt{(1 + 1/n)^2(0.25) - 1/n}$. At high temp. the use of Bailey's formula $R = re(0.217p/\tau)$ is recommended where τ is the tangent tension for the outer surface of the cylinder. At high pressures the outer layers of the cylinder are destroyed first. The inner layers can

withstand pressures much higher than the limit of elasticity which should cause a plastic deformation. The plastic flow and the destruction begin only when the critical pressure reaches the outer radius. W. R. Henn

Improved counting rate meter. Robley D. Evans and Robert L. Alder. *Rev. Sci. Instruments* **10**, 332–6(1939). E. H.

A direct-reading counting rate ratio meter. Robley D. Evans and Ralph E. Meagher. *Rev. Sci. Instruments* **10**, 339–44(1939). E. H.

An automatic Pirani vacuum gage. E. J. Scott. *Rev. Sci. Instruments* **10**, 349–50(1939). E. H.

An improved agar bridge for pH measurements. A. van Kreveld. *Chem. Weekblad* **36**, 786–7(1939).—The improved agar bridge permits accurate pH measurements with an ordinary galvanometer. It is a combination of the usual KCl bridge and an agar bridge. With the latter it shares a low elec. resistance (500 ohms), with the former a regulated renewal of the boundary surfaces. The results of the measurements of some buffers with Pt quinhydrone electrodes at 20° are given. A. H. Krappe

Cloud chamber control circuit. I. A. Getting. *Rev. Sci. Instruments* **10**, 323–4(1939). E. H.

Exhaust valve for pneumatic cloud chambers. Lewis Fussell, Jr. *Rev. Sci. Instruments* **10**, 321–2(1939). E. H.

A useful expansion chart. W. F. Schaphorst. *Ind. Eng. Chem., News Ed.* **17**, 790(1939).—A nomographic chart with scales showing temp. differences in degrees F., total expansion in inches, and length of pipe in ft.; the expansion in piping, rods, tubes, etc., can be found directly and simply. W. C. Ebaugh

How many gallons in any vertical cylindrical tank? W. F. Schaphorst. *News Ed. (Am. Chem. Soc.)* **18**, 14 (1940).—A nomographic chart answering the above question for tanks of any height from 2 to 600 in., and for any diam. from 3 to 1000 in. (max. capacity of chart = 2,000,000 gal.). W. C. Ebaugh

Unit processes—background and objects. R. Norris Shreve. *Ind. Eng. Chem.* **32**, 145–6(1940).—An address. G. G.

Separation processes. The principle of minimum dilution in design of new or unusual processes. Merle Randall and Bruce Longtin. *Ind. Eng. Chem.* **32**, 125–9 (1940); cf. *C. A.* **32**, 8217[9], 8840[2]; **33**, 2[2], 1570[1], 2831[8], 3244[1], 9053[5,6,7].—To obtain the highest thermodynamic efficiency in a sepn. process, the streams mixed should be potentially as near at equil. as possible. Examples of violations of this principle in binary fractional distn. are given, and the resulting inefficiencies are traced. Such faulty operating methods can be recognized graphically, as shown in distn. by use of either the McCabe-Thiele (*x-y*) or the Ponchon-Savarit (*H-N*) diagram. Other applications are suggested. R. W. Higbie

Means of measuring turbidity and fluorescence using the Lovibond tintometer fitted with Rothamsted device. G. S. Fawcett and J. Hewitt. *J. Soc. Chem. Ind.* **58**, 342–4(1939).—The Lovibond-Schofield app. is a modification of the Lovibond tintometer and consists of a white light cabinet contg. 2 standard light sources, 2 $MgCO_3$ blocks, or 1 block and a sample. The $MgCO_3$ block and sample are illuminated at 45° and these are viewed through an eyepiece which brings the 2 fields into juxtaposition. With this modification of the app. and when fuller's earth is used in a 5¼ in. cell, readings indicating turbidities greater than 10 particles per hundred thousand are accurate. By inserting a nephelometer cell, turbidities from 0 to 10 per hundred thousand can be accurately measured. H. E. Messmore

The precision conductivity-bridge assembly. W. F. Luder. *J. Am. Chem. Soc.* **62**, 89–95(1940).—The use of recent developments of communication engineering in the cond.-bridge assembly was studied. This study shows that simplification, ease of construction, and lowered cost can be obtained with no loss in precision and with some gain in convenience in the operation of the bridge. Several different forms of the oscillator and its power supply, of the bridge network, and of the amplifier were constructed and tested. An adaption of a new and simple low-distortion oscillator to cond.-bridge use is described. Sep. detector terminal balance to ground is suggested. A two-stage untuned amplifier with gain sufficient to permit balancing the bridge to 1 or 2 parts per million when oscillator harmonics, a. c. hum, and stray pickup have been practically eliminated is suggested for ordinary use of the bridge. A three-stage tuned amplifier is described. A. B. Garrett

Analytical study of drying. P. Arribat. *Mém. poudres* **29**, 12–48(1939).—Math. A. J. Phillips

Typical dryer calculations. O. A. Hougen. *Chem. & Met. Eng.* **47**, 15–17(1940). E. H.

Improved magnesite crucible. Welton J. Crook, John R. Cunningham and James R. Cady. *Ind. Eng. Chem., Anal. Ed.* **12**, 48–51(1940).—Crucibles formed from magnesite brick, contg. iron oxide and silica, and fired at 2000° in an induction furnace are more impervious to fused slags than the com. variety. H. G. Bowlus

Continual observation of changes in weight at oven temperatures. A. C. Beckel and A. G. Sharp. *Ind. Eng. Chem., Anal. Ed.* **12**, 45–7(1940).—A Jolly spring balance suspended above a controlled atm. oven is used to measure rates of drying and oxidation of oils. H. G. Bowlus

Method for assembling thermocouples. H. M. Trimble. *Ind. Eng. Chem., Anal. Ed.* **12**, 52(1940).—Braided Fiberglas sleeving is used to cover a thermocouple wire bundle. H. G. Bowlus

An accurate gas thermostat. L. Levenbook. *Microscope Entomol. Monthly* **3**, 265–6(1939).—An inexpensive Hg app. for maintaining the temp. of molten paraffin embedding baths is described and illustrated. L. Wilson Greene

Acid-base catalysis in depolymerization of dimeric glycolaldehyde [microdilatometer] (Bell, Hirst) **2**.

McPherson, William, Henderson, William Edwards, and Fowler, George Winegar: Laboratory Units in Chemistry. New York: Ginn & Co. 329 pp. $.80. Reviewed in *J. Chem. Education* **16**, 598–9(1939).

Countercurrent contact apparatus. Donald S. McKittrick (to Shell Development Co.). Can. 385,775, Dec. 19, 1939. Structural details are described of an app. for countercurrent contact treatment of a liquid with fluid of a lower sp. gr. than the liquid and at least partially immiscible therewith.

Flotation cell. Wm. J. McKenna (to International Smelting and Refining Co.). U. S. 2,178,239, Oct. 31. Various structural and operative details of a cell provided with an impeller.

Apparatus suitable for measuring and recording elongation and compression of specimens of materials under test. Jens Sivertsen (to Tinius Olsen Testing Machine Co.). U. S. 2,176,016, Oct. 10. Various structural, elec., mech. and operative details.

Flushing equipment for scrubbers and other gas-washing apparatus. N. S. Lazarev. Russ. 51,749, Sept. 30, 1937. Construction details.

Use of filter paper. Alfred E. Squire. U. S. 2,171,484, Aug. 29. A filtering device for use in funnels is prepd. by taking a sheet of filter paper of substantially semicircular shape with a flange projecting along its diametrical line, folding the sheet about a radial line perpendicular to the diametrical line so as to form two quadrants of a circle, securing together the superimposed parts of the projecting flange portion, folding the secured flange portions about the diametrical line and then opening the two quadrants to form a conical structure.

Air filter. Games Slayter (to Owens-Corning Fiberglas Corp.). U. S. 2,178,614, Nov. 7. Fibrous material such as glass wool is used with a viscous coating of an oil and a Zn soap mixed with the oil. Cf. *C. A.* **33**, 6661[8].

Air filter for wet duct humidifier systems. Agnew H.

Bahnson (to The Bahnson Co.). U. S. 2,178,463, Oct. 31. Various structural, mech. and operative details.

Apparatus for cleaning and filtering air. Theodore W. Hallerberg (to United Specialties Co.). U. S. 2,179,229, Nov. 7. Various structural details.

Filter press. Alonzo L. Bausman. U. S. 2,178,416, Oct. 31. Various structural, mech. and operative details.

Medium suitable for use in filtering cleaners' naphtha, etc. Wm. H. Alton (to R. T. Vanderbilt Co.). U. S. 2,179,028, Nov. 7. Finely divided pyrophyllite is used with an admixt. of fibrous talc 5–50%.

Apparatus for extracting hops, ginger roots, etc., by aqueous liquids, etc. Charles G. Kummerlander. U. S. 2,178,207, Oct. 31. Various structural and operative details of an app. including a retort and superposed condenser, etc.

Separating device (for connection in pipe lines) for removing condensate from steam or other vapors or gases. Pasquale Pascale (to Novo Patents, Inc.). U. S. 2,178,240, Oct. 31. Various structural details.

Device for separation of minute liquid particles from swiftly moving gas. Charles G. Hawley (to Centrifix Corp.). Can. 384,786, Oct. 24, 1939.

Apparatus for magnetic separation of dry materials such as ore constituents. Augustin L. J. Quenau. U. S. 2,177,809, Oct. 31. Various structural and operative details.

Separation of powdered materials. Nikolai Ahlmann (to F. L. Smidth & Co.). Can. 384,465, Oct. 3, 1939. Operative and structural details.

Fractionating finely divided solid particles such as those of crude clays. Sanford C. Lyons (to Bird Machine Co.). U. S. 2,179,154, Nov. 7. An arrangement of app. is described, and a process of fractionating finely divided solid material of widely varying particle size, including a fraction of such fine particle size as tends to interfere materially with selective gravitational settling of coarser particles from an aq. suspension of such material, which comprises centrifuging an aq. suspension of such material to deposit centrifugally substantially all but the very finest particle fraction, resuspending the centrifugally deposited fraction in water, and gravitationally settling from the resulting suspension the coarsest particle fraction while maintaining above and removing from the gravitationally settled fraction an aq. suspension of the intermediate-size particle fraction.

Apparatus for producing gas and dry residue. Charles Ness and Hugo V. Kojola (to Dominion Oxygen Co., Ltd.). Can. 385,463, Dec. 5, 1939. A gas and a substantially dry residue, e. g., C_2H_2 and $Ca(OH)_2$, are produced by reaction of a solid and liquid in amts. proportioned to complete the reaction. After the reaction is complete the solid residue is withdrawn from the reaction zone, and the gas is sepd. from the solid.

Gas-pressure governor. Frederick O. Horstmann and Percival F. Horstmann. U. S. 2,173,416, Sept. 19. Various details.

Regulating the penetration of liquids such as those used for cleaning air filters. Ralph D. Petre. U. S. 2,178,701, Nov. 7. Various details of app. and operation in which centrifugal action is utilized to counteract and limit penetration of applied liquid.

Device (with an adjustable overflow) for dipping and measuring liquids. Herman Siemund (to Joe Lowe Corp.). U. S. 2,178,524, Oct. 31. Various structural and operative details.

Classification system for pulverized materials. Harlowe Hardinge (to Hardinge Co., Inc.). Can. 385,343, Nov. 28, 1939. Structural details.

Crushing, grinding and classifying mill. William W. Gibson. Can. 385,405, Dec. 5, 1939. Structural details.

Spray coating device. David A. Wallace (to Chrysler Corp.). U. S. 2,177,851, Oct. 31. Various details of a device suitable for spraying coating materials with compressed air.

Apparatus for continuous mixing, homogenizing or drying of various solid and liquid materials. Pieter Smit (to N. V. Octrooien Maatschappij "Activit"). U. S. 2,177,910, Oct. 31. A mixing and homogenizing app. suitable for use in the manuf. of activated carbonaceous materials, etc., comprises a longitudinal trough, a conveying screw disposed above and parallel with the trough, inlet means above and at one end of the screw for admitting material thereto, at least one shaft rotatably mounted in the trough and parallel with the screw, the shaft being provided with agitating elements and a partition disposed at the end of the trough opposed to the inlet means for permitting discharge of the material only by the conveyor screw, whereby the material carried by the conveyor screw falls by gravity from the screw into the trough and is thrown up again to the screw by the agitating elements thereby effecting the conveying of the material separately from mixing.

Centrifugal drier suitable for treating sand, coal, gravel, etc. Claude M. Garland. U. S. 2,178,750, Nov. 7. Various structural, mech. and operative details.

Regenerative apparatus (with a cylindrical wire screen) for heating and cooling gases such as air and combustion gases. Erik T. Linderoth. U. S. 2,178,481, Oct. 31. Various structural details.

Thermometer mounting for side walls of tanks. Geo. J. Oestreicher. U. S. 2,178,697, Nov. 7. Various structural details.

Temperature-compensated indicating instruments. Hans Loen (to Bendix Aviation Corp.). U. S. 2,178,799, Nov. 7. Various structural and operative details.

Electrical system for automatic control of temperature conditions, etc. Albert Callender and Allan B. Stevenson (to Imperial Chemical Industries Ltd.). U. S. 2,175,985, Oct. 10. Various structural, elec. and operative details of app. for automatic control of a steam supply, etc.

Thermostatic control suitable for use with laboratory ovens. Hugo Romander (to Federal Telegraph Co.). U. S. 2,170,664, Aug. 22. Various structural and operative details.

Heat-exchange apparatus (of the header and parallel tube type) suitable for cooling water, etc. Harry P. Bowser (to H. P. Bowser Mfg. Co.). U. S. 2,178,095, Oct. 31. Various structural details.

Soaking pits for heat treatments. Levi S. Longenecker. U. S. 2,178,668, Nov. 7. Various details of cover mounting and construction.

Regulating the humidity of air with use of a hygroscopic solution such as one of calcium chloride. Robert B. P. Crawford. U. S. 2,177,869, Oct. 31. App. and various operative details are described.

Absorption refrigerating system suitable for use with ammonia, etc. Rudolph S. Nelson (to Hoover Co.). U. S. 2,178,603, Nov. 7. Various details of app. and operation.

Absorption refrigerating systems, suitable for operation with ammonia, etc. Curtis C. Coons (to Hoover Co.). U. S. 2,178,560–1, Nov. 7. Various details of app. and operation.

Absorption refrigerating systems such as those utilizing ammonia and inert gas. Curtis C. Coons (to Hoover Co.). U. S. 2,178,869–70, Nov. 7. Various details of app. and operation.

Acetylene from other hydrocarbons. Floyd J. Metzger (to Air Reduction Co.). U. S. 2,179,378, Nov. 7. App. is described, and a process involving introducing into a large combustion and reaction chamber a large number of sep. high-velocity jets of a hydrocarbon such as C_3H_8, etc., and of O directed to cause commingling and combustion in a localized and regulated manner and blending of the jets and combustion products. U. S. 2,179,379 describes an app. and a process of producing acetylene from hydrocarbons such as those of petroleum by combustion with O insufficient for complete combustion and in the presence of steam (various operative details being described).

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Ivan Evgrafovich Adadurov. Anon. *Trudy Khar'kov. Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 5–11(1939).—A brief account of the accomplishments of I. E. Adadurov including a list of his works. B. Z. Kamich

Pietro Spica. Efisio Mameli. *Gazz. chim. ital.* **69**, 479–98(1939).—An obituary, with a bibliography of 222 publications by S. and his collaborators. C. C. Davis 2

The atomic hypothesis of William Higgins. Edward R. Atkinson. *J. Chem. Education* **17**, 3–11(1940). E. H.

The historical and industrial discovery of the elements. 3 I. J. Newton Friend. *Chemistry & Industry* **1939**, 1104–7. II. *Ibid.* **1940**, 24–6. E. H.

Chemistry in public junior colleges. A comparison of 1938 with 1928–29. Maurice R. Amsden and Stanley W. Morse. *J. Chem. Education* **17**, 31–5(1940). E. H.

Does high-school chemistry function in college? Vernon K. Krieble. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 27–8(1939).—Accrediting authorities are too lenient with respect to chemistry. Leopold Scheflan 4

Does high-school chemistry function in college? Harold A. Iddles. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 74–8(1939).—The secondary school contribution is extremely important and does function materially in college work. Leopold Scheflan

A high-school course in chemistry which does not lead to repetition in college. P. M. Glasoe. *J. Chem. Education* **17**, 11–15(1940). E. H.

Teachers and textbooks. George W. Fowler. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 28–32(1939).—An address on the teaching of chemistry in high schools. 5 Leopold Scheflan

Lecture demonstrations. Grover C. Greenwood. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 32–3(1939).—Demonstrations are described on fires, the extinguishing of a fire and on spontaneous combustion. L. S.

Teaching problems in presenting the law of chemical equilibrium to students in analytical chemistry. C. S. Adams. *J. Chem. Education* **17**, 22–9(1940). E. H. 6

Approximate solutions to problems involving the ideal gas law. Alexander Calandra. *J. Chem. Education* **17**, 15–17(1940). E. H.

Recent advances in physics. Thomas H. Osgood and Ralph B. Bowersox. *News Ed. (Am. Chem. Soc.)* **18**, 30–1, 34(1940). E. J. C.

The charcoal-iron industry. The attempts to discover a substitute for charcoal, mainly in the eighteenth century and with particular reference to the Royal Society of Arts MSS. H. Gwynn Jones. *J. Roy. Soc. Arts* **88**, 41–57 (1939); *Foundry Trade J.* **61**, 353–4. E. H. 7

Further experiments on the decomposition and regeneration of nitrogenous organic matter in sea water. Theodor v. Brand, Norris W. Rakestraw and Charles E. Renn. *Biol. Bull.* **77**, 285–96(1939); cf. *C. A.* **31**, 4545[2]; **33**, 3642[5].—Successive cycles of decompn. and regeneration of nitrogenous org. and inorg. compds. can be effected aerobically by innoculation with living diatoms (*Nitzschia closterium*) at any stage of the N cycle. At the expense of particulate N, NH_3 increases for 1 month in the first cycle, less rapidly in the second. Nitrite begins to appear after 1–2 months as NH_3 starts to disappear, nitrate as nitrite lessens. Anaerobically (in H_2) H_2S appears; particulate N diminishes less slowly than aerobically. J. McA. 8

Hydrographic features of the waters of Saint John Harbor. H. R. Hachey. *J. Fisheries Research Board Can.* **4**, 424–40(1939).—The temp. of the surface waters of St. John Harbor seldom exceeds 15.0°, while bottom waters probably never reach 15.0°. During the colder months of the year, water temps. are seldom lower than 0.0°. Salinities based on 1 year's observations indicate that the mean monthly salinity of surface waters ranges from 5.1% to 23.3%. The salinity distribution of the harbor waters varies greatly with the phase of the tide. After a dry summer, with comparatively small discharge from the river, the salinity at any phase of the tide did not fall below 22.0%. Salinities greater than 32.0% penetrated the harbor at the greatest depths. At the times of the spring freshets, the harbor was thoroughly bathed, at certain phases of the tide, with waters of a salinity less than 5.0%, and at other phases, with a salinity greater than 30.0%. A well-marked gradation in salinity was noted proceeding seaward from the reversing falls. Formulas are derived to express the annual variation of water temps., and the relation between harbor salinities and river discharge. Dorothy A. Meyer 9

Measurements of atmospheric ozone at Bombay. M. W. Chiplonkar. *Proc. Indian Acad. Sci.* **10A**, 105–20 (1939).—Daily measurements during 2 yrs. yield averages and show seasonal variations that agree with those of Dobson's world-wide survey (O_3 equiv. to a thickness of 0.213 cm.). The annual curve, however, shows an unusual depression during the monsoon months (July and Aug.) and a peak during Sept. and Oct. There is practically no correlation between the daily value of O_3 and the pressure at ground level. Wm. E. Trout, Jr.

Attempt to solve some problems of nomenclature. G. A. Butkevich. *Uspekhi Khim.* **8**, 593–603(1939).—Some suggestions are made as a basis for discussion on changes in Russian chem. nomenclature. F. H. Rathmann

Nomographic methods of calculation in physical chemistry. G. V. Vinogradov. *Uspekhi Khim.* **8**, 378–438 (1939).—Examples for electrode potentials, radius of colloid particles, rate of sedimentation of aerosols, relative nos. of gas mols. the energies of which exceed a given value, dissocn. consts., mean free path, Planck-Einstein function, Debye-Hückel activity coeffs., vol. of satd. vapors, activity coeffs., adsorption coeffs., vapor pressure are given in 16 nomograms. 152 references. F. H. Rathmann

The intermolecular potential of mercury. J. H. Hildebrand, H. R. R. Wakeham and R. N. Boyd. *J. Chem. Phys.* **7**, 1094–6(1939).—The distribution function for Hg (−35 to +250°) (*C. A.* **33**, 9082[7]) and the Hildebrand-Wood equation (*C. A.* **28**, 955[2]) are used to calc. the intermol. potential. This potential is $\epsilon = (j/r^n) - (k/r^6)$ (where $j = 5.49 \times 10^{-9}$, $k = 3.52 \times 10^{-10}$, ϵ is in dynes, r in A.). The value of k checks well with the value 3.35×10^{-10} calcd. from the London formula (*C. A.* **31**, 2882[9]) for dispersion potential. Several other independent checks agree with this potential function within the apparent limits of error of each. G. M. Petty 10

Free hydroxyl. V. N. Kondrat'ev. *Uspekhi Khim.* **8**, 195–240(1939).—Theoretical and review. K. discusses spectroscopic data on the OH mol., the thermal dissocn. of H_2O, O_2, H_2 and OH, production of OH during elec. discharge through H_2O and H_2O_2 vapors, and in a hydrogen flame. OH is present in a non-equil. state and plays an important role in the mechanism of combustion of H_2, NH_3, PH_3, H_2S, H_2CO_3 and of hydrocarbons. F. H. Rathmann 11

Diamagnetism of gases and vapors. Ya. Shur. *Uspekhi Fiz. Nauk* **20**, 410–46(1938).—In a theoretical and math. review, Shur discusses the classical and quantum theories of diamagnetism, and the methods of calcn. of the magnetic susceptibility. He then discusses various exptl. data for N_2, H_2, CO_2, He, Ne, A, Kr, Xe, CH_4, C_2H_6, C_2H_2, CS_2, C_6H_6, $(H_2O)n$, Br_2 and Hg. Using a method of his own (cf. *C. A.* **31**, 4862[3]) and also Yanus and Shur, (*Compt. rend.* (U. R. S. S.) **2**, 465(1934)). Shur obtained the following values for $-\chi \times 10^6$; CS_2 gas 0.53, C_6H_6 gas 0.75, liquid CS_2 0.56–0.59, liquid C_6H_6 0.71–0.73, Br_2 gas 0.46, liquid or solid Br_2 0.40, Hg gas 0.39, Hg ion 0.20. The exptl. values agree best with the values calcd. by Slater's method. F. H. Rathmann

Dependence of ferromagnetic anisotropy on the field

strength. L. P. Tarasov. *Phys. Rev.* **56**, 1224–30(1939). —In evaluating the anisotropy consts. of ferromagnetic materials a common method is to measure the torque exerted on a specimen of circular section by a uniform magnetic field, to det. the max. torque by extrapolation to infinite field strength, and to multiply this by an appropriate no. The law of approach of the torque T_H to its limiting value T_∞ is $T_H = T_\infty (1 - H_0/H_a)$ for disks and ellipsoids of single crystals of Fe-Si alloys contg. up to 7.4% Si, and for polycryst. disks of Fe and of Si steel. H_a is the strength of the applied field uncorrected for demagnetizing field and H_0 is a const. which depends mostly on the dimension ratio of the disk. This law is discussed in relation to a similar law proposed by H. Schlechtweg (*C. A.* **31**, 1668[3]), and to the familiar law of approach of magnetization to satn. For disks the approach to satn. of the torque peaks is connected with the lack of magnetic satn. at their edges. G. M. Petty

Ferromagnetic anisotropy of iron and iron-rich silicon alloys. L. P. Tarasov. *Phys. Rev.* **56**, 1231–40(1939); cf. *C. A.* **33**, 2091[5].—The ferromagnetic anisotropy const. K_1 was measured by the magnetic torque method for Fe alloys contg. up to 13.7 at. % Si. For $A < 9.86$, $K_1 \times 10^{-5} = 5.20–0.279A$. For $A < 9.86$, $K_1 \times 10^{-5} = 4.43–0.1915A$. K_1 is expressed in ergs/cc.; A is the at. percentage of Si. Akulov's value for Fe (*C. A.* **24**, 536) is unreliable, as it is an av. of discordant results. The present theory of ferromagnetic anisotropy is in need of revision, possibly in connection with the higher order terms in the magnetic energy equation. The change in slope in the K_1-A curve occurs at nearly the same concn. as the similar change in slope found by Jette and Greiner for the lattice parameter a_0 (*C. A.* **27**, 2922). An attempt is made to explain the occurrence of these breaks in terms of a change from a hypothetical superlattice with a Si concn. of $^3/_{32}$ to a partially formed Fe_3Si superlattice. G. M. Petty

Ferromagnetic anisotropy of low-nickel alloys of iron. L. P. Tarasov. *Phys. Rev.* **56**, 1245–6(1939); cf. preceding abstr.—The anisotropy of low-Ni (0–17 at. %) alloys of Fe decreases linearly from 5.29×10^5 ergs/cc. for Fe to $\sim 1.3 \times 10^5$ ergs/cc. for 17 at. % Ni. G. M. P.

Volume determination by dielectric measurement. H. Ulich and H. van den Berge. *Chem. Fabrik* **1939**, 512–13.—The method was developed to measure the concn. and d. of solns. of C_2H_2 in Me_2CO with respect to temp. and pressure, but may be used for other purposes. It depends on the fact that the capacity of an elec. condenser partly submerged in the soln. depends on both the dielec. const. of the soln. and the depth of submergence. A cut of the app. is shown, the method is described and math. formulas are given. J. H. Moore

The dielectric behavior of colloid systems. H. Schaefer and Stachowiak. *Kolloid-Z.* **89**, 311–16(1939).—A modified app. for detg. the dielec. const. of colloidal substances (in this case animal liver tissue) is described. The effect of colloidal structure on the dielec. const. is discussed. The dielec. const. depends on the frequency (wave length) and temp., and is affected by the structure of the particle, especially in the case of biol. materials such as proteins. S. I. Aronovsky

Dipole moment of 1-chloroanthraquinone. Ernst Bergmann and Anna Weizmann. *J. Am. Chem. Soc.* **61**, 3583(1939); cf. *C. A.* **32**, 7445[5].—Repetition of previous work shows that the dipole moment of 1-chloroanthraquinone in C_6H_6 and dioxane is 1.8, and 1.9D., resp.; Fischer and Rogowski (*C. A.* **33**, 7633[3]) give 1.53 (C_6H_6) and 1.55 (dioxane). C. J. West

Dipole moment and alkyl chain length. H. O. Jenkins. *Nature* **144**, 667–8(1939).—When the dipole moment μ is plotted against $1/r^2$, where r is the distance between the C° of the ring and the terminal C atom in the side chain (H in the case of C_6H_6), a straight line is obtained for C_6H_6, PhMe, PhEt and PhPr. The limiting value of μ is 0.69D. G. M. Petty

The heat capacity of cyanogen gas. E. J. Burcik and Don M. Yost. *J. Chem. Phys.* **7**, 1114–15(1939); cf. following abstr.—The observed values of $C_p°$ (in cal./deg.) at infinite diln. are: 273.16° abs., 13.14 ± 0.02; 296.36° abs., 13.46 ± 0.02; 326.91° abs., 13.96 ± 0.02. These are compared with calcd. values. G. M. Petty

The heat capacity of cyanogen gas. F. Stitt. *J. Chem. Phys.* **7**, 1115(1939); cf. preceding abstr.—The observed values of $C_v°$ at 0.01 mm. pressure lie in the range 9.59–9.61 at 185.2°K., 12.04–12.05 at 294.1°K., 12.29–12.42 at 320.4°K. These are compared with calcd. values. G. M. Petty

The flow of gases through metal capillaries at low pressures. Hirosi Adzumi. *Bull. Chem. Soc. Japan* **14**, 343–7(1939).—A graph of the rate of flow of H per unit pressure *vs.* pressure goes through a min. This effect which was observed in Ag, Al, Cu and Fe capillaries can be explained in terms of adsorption on the capillary walls. S. B. S.

Kinetic processes in an expansion cylinder. Walther Meissner and Gertrud Meissner. *Ann. Physik* **36**, 303–18(1939).—A kinetic treatment of a gas expanding adiabatically against a piston moving with const. velocity shows that the pressure exerted on the piston agrees to within a negligible amt. with the pressure for very small piston velocity. More general cases of expansion are handled qualitatively. Henry C. Thomas

Equation of state for gas mixtures. I. R. Krichevskiĭ and Ya. S. Kazarnovskiĭ. *J. Phys. Chem.* (U. S. S. R.) **13**, 378–96(1939); cf. *C. A.* **33**, 6104[4]. F. H. R.

On the *p-v-T* relations and an equation of state for unsaturated vapors of methyl alcohol. L. Lashakov. *Acta Physicochim. U. R. S. S.* **11**, 107–16(1939)(in English).—Exptl. data obtained over the range 170–290° and 10–95 atms. yield pv values about 4% lower than those obtained by Ramsay and Young. By use of the Beattie and Bridgeman equation (*C. A.* **21**, 3146) the av. difference between exptl. and calcd. values is 0.21%. F. H. R.

Extinction limits of flames. W. P. Jorissen. *Chem. Weekblad* **36**, 815–20(1939).—A survey of research on the extinction limits of flames from the 18th century (Priestley) to the present day is given, with figures for the more common gas mixts. in a table. 41 references. A. H. K.

A definition of real fluids. Walter S. Hill. *Anales asoc. quím. farm. Uruguay* **41**, 64–71(1938)(Pub. 1939).—The following general definition of a fluid is proposed: A real fluid is a continuous material system capable of perfect mobility (i. e., with zero work) under all infinitesimal deformations that leave the elemental vol. and the areas that limit the different portions of the system unchanged. It is shown mathematically that this definition leads to the classical expressions for internal equil., for Laplace's law of superficial equil. and for the condition of equil. with the surroundings. Iver Igelsrud

The nature of the liquid state. Wm. Band. *J. Chem. Phys.* **7**, 1114(1939); cf. *C. A.* **33**, 5249[3].—A general discussion. G. M. Petty

High-pressure vapor-liquid equilibrium for the systems propylene–isobutane and propane–hydrogen sulfide. E. R. Gilliland and H. W. Scheeline. *Ind. Eng. Chem.* **32**, 48–54(1940); cf. *C. A.* **33**, 9071[1].—*P-T-x-y* data were obtained for the propylene-isobutane and H_2S-propane systems. A comparison between exptl. values and those calcd. from the K charts indicate that the latter are in considerable error in the critical region. A general empirical correlation is presented for predicting phase equil. data for two-component hydrocarbon systems in the critical region. Joseph H. Wells

Thermodynamic properties of the hexyl alcohols. III. 2-Methyl-3-pentanol and 3-methyl-3-pentanol. Frank Hovorka, Herman P. Lankelma and Abraham E. Axelrod. *J. Am. Chem. Soc.* **62**, 187–9(1940); cf. *C. A.* **32**, 4400[6].—The surface tension, d., viscosity and vapor pressure were detd. for 2-methylpentanol-3 and 3-methylpentanol-3 over the temp. range from 5° to the b. p. The n was detd. from 15 to 45°. The av. heat of vaporization, the consts. for Rankine's Eötvös relation, total surface energy, and the crit. consts. were calcd. The heats of vaporization are 10,624 and 10,057 cals., the b. ps. 126.68 ± 0.02° and 120.91 ± 0.02° and Trouton's const. 26.6 and 25.5 for the two alcs., resp. The high values of Trouton's const. indicate varying degrees of assocn. This conclusion is also

indicated by the values of the Eötvös const., parachor, and total surface energy. A. B. Garrett

Interfacial activity of short-chain isomers. C. C. Addison. *Nature* **144**, 783(1939); cf. *C. A.* **32**, 1161[8], 2805[7].—Interfacial tensions (dynes per cm.) were detd. between pure water and (1) C_6H_6, 35.41; (2) 1% *trans*-$Cl_2Pt(SEt_2)_2$ in C_6H_6, 35.30; (3) 1% *cis*-$Cl_2Pt(SEt_2)_2$ in C_6H_6, 28.62; between C_6H_6 and 1% aq. solns. of maleic, fumaric and *trans*-mesaconic acid, 35.41; *cis*-citraconic acid, 28.51. Similar differences are reported between *cis*- and *trans*-benzaldoxime, and between structural isomers such as the toluic acids, cresols, phthalic acids and butyl alcs. G. M. Petty

A modified method of using Poiseuille's apparatus. J. Bhimasenachar. *Proc. Indian Acad. Sci.* **10A**, 141–4 (1939).—Viscous liquids, e. g., glycerol, are forced by pressure of dry air through a horizontal glass capillary of cross section 0.0008005 sq. cm. and length 30.5 cm. A bulb at one end facilitates filling. The motion of a small pellet of Hg, trapped in the capillary, between marks 16.58 cm. distant indicates the rate of flow of the liquid, from which the viscosity can be obtained. For glycerol, the viscosity $\eta_T = Ae^{B/T}$, where $A = 7.23 \times 10^{-9}$ and $B = 6125$. Wm. E. Trout, Jr.

The viscous force between almost-coaxial cylinders. D. R. Inglis. *Phys. Rev.* **56**, 1041–4(1939).—The math. theory of the flow between a rotating and a stationary cylinder, which are not perfectly coaxial, and the theory of the torque on the stationary cylinder are discussed. S. Bradford Stone

The viscosity of liquid hydrogen. H. E. Johns. *Can. J. Research* **17A**, 221–6(1939).—The viscosity of liquid hydrogen was measured by observing its flow through a variety of capillary tubes. The resulting viscosities are about 10% higher than those obtained by Keesom and Macwood (*C. A.* **32**, 8229[4]) using an oscillating disk. J. W. Shipley

The change in electrical resistance of alkali metals on melting. Akira Harasima. *Proc. Phys.-Math. Soc. Japan* **21**, 679–86(1939).—Math. The $R_{liq.}/R_{solid}$ ratio is derived from theoretical considerations and found to agree with exptly. observed values. The temp. coeff. of the resistance of a liquid was derived and was found to give results of the right order of magnitude. The authors criticized their theory from the point of view of the theory of Wigner and Seitz. Frank Gonet

The adiabatic piezo-optic coefficients of water and the alcohols. K. S. Venkataraman. *Proc. Indian Acad. Sci.* **10A**, 121–40(1939).—The following adiabatic piezo-optic coeffs. ($(\partial n/\partial p)_\phi \times 10^6$) were obtained by the method of Raman and Venkataraman (*Proc. Roy. Soc.* (London) **A171**, 137(1939)): 34.52 for MeOH at 24.4°, 36.12 for EtOH at 24.0°, 33.54 for *n*-PrOH at 24.1°, 37.30 for *i*-PrOH at 25.5°, 32.95 for *n*-BuOH at 24.5°, 36.07 for *i*-BuOH at 25.5°, 34.15 for *n*-AmOH at 26.1°, and 14.66 for H_2O at 23.1°. The temp. coeffs. of the refractive indexes, $(\partial n/\partial T)_p \times 10^6$, were, resp., −37.5, −39.8, −40.5, −43.5, −41.1, −41.8, −41.1. The elasto-optic coeffs. calcd. for pressure changes at const. temp. and at const. entropy were always higher than the theoretical value given by the Lorentz formula. The difference between the value at const. temp. and the theoretical value, resulting from the anisotropy of the polarization field, is considerably smaller in the alcs. than in CS_2 or benzene. The elasto-optic coeff. calcd. for temp. changes approaches the values given by the Lorentz formula for the higher alcs. The pure temp. coeff. of *n* is pos. in MeOH and EtOH and neg. from *n*-PrOH on. Wm. E. Trout, Jr.

The interpretation of atomic distribution curves for liquids. C. A. Coulson and G. S. Rushbrooke. *Phys. Rev.* **56**, 1216–23(1939).—Math.-theoretical. The theory, applied to liquid Na, gives a latent heat of melting in fair agreement with expt. There is a change of structure on melting. If the parameters in a partition function developed in this way are chosen to agree with any one phys. property, it is incorrect to add terms representing "communal entropy." G. M. Petty

The extraction of ferric iron from hydrochloric acid solutions by dichloroethyl ether and the formula of the iron compound in the ether. Joseph Axelrod and Ernest H. Swift. *J. Am. Chem. Soc.* **62**, 33–6(1940).—The mutual soly. of dichloroethyl ether with HCl solns. is so small that extns. are practical with even quite concd. acid solns., and so little acid passes into the ether phase that conditions are favorable for studying the assocn. of HCl with the iron. The distribution data of $FeCl_3$ between HCl solns. and β,β-dichloroethyl ether indicate that this ether can be used for the quant. extn. of $FeCl_3$ from solns. greater than 7 *N* in HCl. Chem. analyses of the ether soln. have shown that 1 mol. of HCl and 4–5 mols. of water are present for each mol. of iron present in the ether layer. If polymerization and the possible presence of ether in the mol. are disregarded, the empirical formula can be written as $HFeCl_4 \cdot 4\text{–}5H_2O$. A. B. Garrett

Evaporation coefficient of polar crystals. Kurt Neumann and Virgil Costeanu. *Z. physik. Chem.* **A185**, 65–80(1939).—The vapor pressure of $KReO_4$ was detd. by the Knudsen effusion method between 780 and 853°K.; the pressures are between 0.26×10^{-3} and 9.55×10^{-3} mm. Hg, resp. $\log p(\text{solid}) = 22.045 + 16092/T$; $\log p(\text{liquid}) = 15.586 + 11666/T$; $\Delta H(\text{solid}) = 73.28$ kg.-cal./mol.; $\Delta H(\text{liquid}) = 53.12$ kg.-cal./mol.; $\Delta H(\text{fusion}) = 20.16$ kg.-cal./mol. From the evapn. velocity of a small crystal of $KReO_4$ into a high vacuum, the evapn. coeff., α, is calcd. to be 0.8. $v_{evapn.} = v_{condensation} = \alpha[N/\sqrt{2\pi MRT}]p$, where v = velocity, N = Avagadro's no., M = mol. wt., p = pressure. Theoretical considerations are given as to the elementary process of evapn. on the surface, edges and corners of the crystal in order to account for the high value of $\alpha = 0.8$. Victor R. Deitz

Photopotential of an element composed of metal-semiconductor-metal. V. Experiments with polycrystalline cuprous oxide specimens at low temperatures. G. Mönch *Ann. Physik* **36**, 1–8(1939); cf. *C. A.* **33**, 4101[1].—Considerable exptl. detail is given. William E. Vaughan

The electric conductivity of the alkali metals in a magnetic field. E. Justi and M. Kohler. *Ann. Physik* **36**, 349–56(1939).—A discussion of exptl. results to appear in *Physik. Z.* The temp. dependence to 14° abs. for zero magnetic field is given by the Grüneisen formula with characteristic temp. $\theta = 199.5°$. A theoretical solution is given of the problem of the change of resistance of the alkali metals for the case of a very strong perpendicular magnetic field with isotropic binding and anisotropic collision frequency. The satn. value of the relative increase in resistance found by expt. is reproduced to order of magnitude by the theory. Henry C. Thomas

Large anisotropy of the electrical conductivity of graphite. K. S. Krishnan and N. Ganguli. *Nature* **144**, 667(1939).—The sp. resistance in the basal plane of graphite is of the order of 10^{-4} ohms per cm.; along the normal to the plane, 2–3 ohms per cm. G. M. Petty

Diffusion of oxygen in copper. C. E. Ransley. *J. Inst. Metals* **65**, Advance copy No. 855, 25 pp.(1939).—The desorption of O from Cu *in vacuo* is controlled by the rate of evapn. from the surface of the metal. CO does not diffuse in solid Cu. When Cu contg. O is heated in CO, the O is removed by a surface reaction. This reaction follows the equation $W^2 = tk$. W is the weight of O removed, t is time, and k is the diffusion const. Log k is a straight-line function with respect to abs. temp. The embrittlement of Cu in reducing atms. is due to the penetration of H. 24 references. J. N. Lynn

Structure and physical properties of thin metallic layers. A. T. Ashcheulov. *Uspekhi Fiz. Nauk* **20**, 481–512(1938).—Review. A. discusses the methods of prepn. and structure detn., elec. cond. and optical properties of thin metallic layers. 208 references. F. H. Rathmann

Growth phenomena in cadmium single crystals and their importance for the investigation of the forces active between lattice atoms. I. N. Stranski. *Ber.* **72A**, 141–8 (1939).—A review. G. G.

Mathematical treatment of structure analyses according to the Debye-Scherrer method. III. The rhombohedral system. P. Adolf Herrlin. *Kgl. Fysiograf. Säll-*

skap. Lund, Handl. **47**, No. 3, 1–10(1936)(in English). IV. **The tetragonal system.** *Ibid.* 11–16.—Math. W. C. Tobie

Atomic parameters of γ-silver-cadmium. Harald Perlitz and Rolf Aavakivi. *Nature* **144**, 708–9(1939).—There is a regular distribution, with Ag in the positions of *B* and *C* atoms and Cd in the position of *A* and *D* atoms; a = 0.105, b = 0.175, c = 0.358, d = 0.310 and e = 0.038. G. M. Petty

Structure and thermal properties associated with some hydrogen bonds in crystals. III. Further examples of the isotope effect. A. R. Ubbelohde. *Proc. Roy. Soc.* (London) **A173**, 417–27(1939); cf. *C. A.* **33**, 4486[4,6].—The effect on the lattice spacings of substituting deuterium for H was investigated for pentaerythritol; $CuSO_4.5H_2O$; $SrCl_2.6H_2O$; fumaric acid; KH_2PO_4; $NaHSO_4$; urea; and KHF_2. U. concludes that when the crystal structure contains hydroxyl bonds the isotope effect is small, and when it contains H bonds there is a marked expansion, which disturbs the lattice sufficiently to lead to sepn. in a new crystal structure (K phosphate). The effect obtained for KHF_2 does not suggest a short H bond in this compd. Short H bonds are believed to require special resonance forces for their explanation. Frank Gonet

Fiber structure in alkali metal wires. Carlo Goria. *Kolloid-Z.* **89**, 325–8(1939); cf. *C. A.* **33**, 8072[9].—X-ray examn. of metals and alloys (Debye-Scherrer method, cf. *C. A.* 12,786) discloses the orientation, as well as the form and size of the cryst. units present; also whether fibers or platlets are formed in the transition stages which are affected by thermal, mech. and crystallographic factors. Quickly cooled wire specimens showed random structure of standard space-centered cubic lattices, where a is 4.27 A. for Na, 5.32 A. for K, and 5.42 A. for a solid soln. of 55% K, 45% Rb. Slow cooling developed a fiber structure, the fiber axis being parallel to the direction [001]. In solid soln. fiber formation is perfect, being undisturbed by changes in vol. Deformation of the wires and pressure developed fibers parallel to the direction [111]; simple tension developed fibers in the direction [110], which is that of greatest lattice density. These results should apply to all alkali metals, which have the same lattice, and the same phys. and mech. properties. The results also indicate the utility of this x-ray method in clearing up obscure points in the constitutional diagrams of binary alloys; they show that the alkali metals have the same lattice at ordinary as at very low temps., and give an insight into fiber structure in metallic wires which accords with our knowledge of the relation between fiber structure and crystal lattice. The work is being continued. Jerome Alexander

Investigation of spiropentane by electron diffraction. Fritz Rogowski. *Ber.* **72B**, 2021–6(1939).—Electron-diffraction patterns of C_5H_8 as prepd. from Zn and tetra-bromopentaerythritol are consistent with the spiropentane configuration. Two cyclopropane rings lie in mutually ⊥ planes with the central C common. Apex angles for each ring are 60° and C-C distances = 1.54A. Two H atoms are assocd. with each outer C atom at distances of 1.08A. The C-H bonds make normal tetrahedral angles. W. F. Bradley

Transformation of organic compounds in the solid state. II. *n*-Tricosanoic acid. Rudolf Kohlhaas and Camill Stuber. *Ber.* **72B**, 1962–9(1939).—Tricosanoic acid (prepd. as in *C. A.* **33**, 3332[4]) crystallizes from acetone as a mixt. of 2 modifications, α- and β-. Both are tabular with rhombic profiles but the profile angles differ. X-ray powder diffraction diagrams, and rotation diagrams from nearly "single crystal" aggregates yield the following unit-cell measurements:

	a	b	$cx \sin \beta$	β
α-form	5.13A.	7.43A.	57.20A.	73.95°
β-form	5.64A.	7.49A.	53.23A.	61.57°

The α-form solidifies from melts, and is derived from irreversible transformation from the β-form at 69.3°. The α-form is consistent with observations by Schoon on other long-chain aliphatic compds. (*C. A.* **32**, 6523[9]). W. F. Bradley

Dynamics of the sorption process. A. A. Zhukhovitskiĭ, Ya. L. Zabezhinskiĭ and D. S. Sominskiĭ. *J. Phys. Chem.* (U. S. S. R.) **13**, 303–10(1939).—The theory of Mecklenburg (*C. A.* 20, 531) is criticized as erroneous and misleading. F. H. Rathmann

Surface compounds. III. Sorption of oxygen by active carbon determined by magnetic measurements. Robert Juza and Robert Langheim. *Z. Elektrochem.* **45**, 689–98 (1939); cf. *C. A.* **32**, 6524[4].—The formation of surface oxide on active carbon was studied in relation to time, quantity of sorbed O and in the temp. range 18 to 200°. App. was designed for measurement of *magnetic susceptibility* at low temps. in any desired gas. The magnetic susceptibility of O adsorbed on carbon at −183° depends upon the d. of the layer of O in the carbon surface. H. Stoertz

Investigation of the structure of gel surfaces. I. Heat of wetting of a silicic acid gel. G. Rykhlikov and B. Bruns. *J. Phys. Chem.* (U. S. S. R.) **13**, 502–7(1939).—The heats of wetting of 3 gels, I—com., II—from HCl, and III—from NH_4Cl, are shown. For I, some heats of adsorption for the given amts. of H_2O adsorbed are: 0%, 17.2 cal./g; 4.08, 12.22; 14.5, 7.02; 25.2, 3.8; for II: 0, 28.2; 5.2, 16.1; 15.2, 9.7; 28.7, 0.59; for III: 0, 24.2; 9.5, 8.9; 16.4, 3.30; 17.2–20.1, 0.0. For I, the adsorption isotherm consists of 2 lines, for II, capillary condensation is indicated, while III obeys the Freundlich isotherm. Since the differential heats of adsorption show 2 max., it is concluded that the surface of the gel consists of several distinct types. F. H. Rathmann

Sorption of water vapor by vermiculite and its silica. L. A. Hansen, W. S. Samuel, Jr., and P. A. Forni. *Ind. Eng. Chem.* **32**, 116–18(1940).—Exfoliated vermiculite, activated at 115° for 48 hrs., has a low capacity for H_2O vapor from air (100% relative humidity) at 25°. The silica (d. about 0.1) obtained from exfoliated vermiculite by acid treatment has high sorptive capacity for H_2O vapor; when activated at 250° the capacity (100 × g. H_2O sorbed per g. silica) is about 13.4 at 100% efficiency at 25° with air satd. with H_2O vapor. There is a slight loss in capacity upon reactivation. Silica prepd. from unexfoliated vermiculite is slightly inferior in sorptive capacity to that obtained from exfoliated mineral. The silica has much less capacity for EtOH than for H_2O; for C_6H_6 the capacity is very small. George Ayers

A theory of the activated adsorption of gases by heteropolar crystals. F. C. Tompkins. *J. S. African Chem. Inst.* **22**, 37–43(1939); cf. *C. A.* **33**, 2012[1].—The theory is an extension of Ward's theory (cf. *C. A.* **26**, 894, 3977) that slow absorption of H_2 by copper is due to the penetration of the gas into Smekal cracks (cf. *C. A.* **22**, 1271) which are known to be present at the surfaces of cryst. solids, by a process of diffusion. The new feature of this theory is that the controlling factor of the rate of absorption is the acquirement of the necessary heat of activation, not by the mols. which enter the Smekal cracks, but by the adsorbed sentinel mols. which line the edge of the crack. This heat of activation is calcd. to be in the order of 6000 cal., which is in agreement with the exptl. values. A. B. Garrett

The adsorption of nonpolar gases on alkali halide crystals. Wm. J. C. Orr. *Proc. Roy. Soc.* (London) **A173**, 349–67(1939); cf. *C. A.* **34**, 666[8].—An exptl. technique sufficiently sensitive to measure accurately the very small amts. of nonpolar gas absorbed on alkali halide crystals (from 0.20 to 0.30 cu. mm./g. salt) and an automatic temp.-control working in the range from 65 to 90°K. are described. Isotherms for A, O and N on KCl and CsI are described and heats of adsorption for A, O and N were found to be 8.3, 8.4, 7.2 × 10^3 g. mol. on KCl and 4.5, 4.0, and 4.0 × 10^3 g. mol. on CsI. The position at which the first monolayer is completed was found to be given by a max. when ΔH is plotted as a function of the amt. absorbed. Good agreement was obtained between the exptl. values and theoretical calcns., where the divergence of the curves at low values of θ can be ascribed to adsorp-

tion taking place in cracks and other irregularities. In the region between the completion of the monolayer and the bulk condensation of a gas an amt. equal to 3 to 4 times that in the first layer is adsorbed; the mols. are arranged in layers rather than in localized aggregates. Frank Gonet

Adsorption of cations on platinized charcoal in a hydrogen atmosphere. S. Petrov, R. Burstein and P. Kisseleva. *Acta Physicochim. U. R. S. S.* **11**, 59–66(1939)(in English).—In a H_2 atm. the adsorption of uni- and multivalent ions on slightly activated platinized charcoal is in the order $Li < Na < K < Cs$ and $K^+ > Ba^{++} > La^{+++}$. On highly activated charcoal the reverse order holds for increasing ionic charge. The practically unchanged adsorption of K^+ and the strongly increased adsorption of the multivalent ions on increasing activation are ascribed to parallel increases in the pore diams. Values for the adsorption calcd. on the basis of Stern's theory agree well with the exptl. data. F. H. Rathmann

Lyotropic series and adsorption. A. R. Docking. *Australian Chem. Inst. J. & Proc.* **6**, 400–6(1939); cf. *C. A.* **33**, 4493⁴.—The adsorption of ions on methylcellulose is given by the following series (order of decreasing adsorption): CNS, I, Br = $C_2H_3O_2$, NO_3 = Cl, SO_4. The effect of salts on the soly. of methylcellulose is in the order KCNS, KI, H_2O, KCl, K_2SO_4, K_2SO_4 decreasing and KCNS increasing the amt. dissolved. From these measurements and those previously made with gelatin as adsorbent it can be concluded that generally those ions that are weakly hydrated are strongly adsorbed by the colloid. Robert Simha

The nature of foam. Tunetaka Sasaki. *Chem. Products* **2**, 143–6(1939); cf. *C. A.* **33**, 9087².—The stability of foam is discussed as well as qual. tests for detg. the effect of alc. and ether on foaming solns., the measurement of the stability of stable and unstable foam (as, e. g., the foam produced in aq. fatty acid or alc. soln.), liquid ternary systems and types of systems. Foams of an aq. soln. of AcOH are decompd. on the addn. of C_6H_6 or hexane (nonpolar liquid) in moderate excess. Foam is produced if water is shaken with relatively small amts. of a hydrocarbon such as hexane obtained by the usual method of repeated distn. from com. products. No foam is produced, however, in the mixt. of hexane and water from which traces of impurities are carefully removed by shaking it a long time with fuming H_2SO_4 and distg. This is a simple but effective method of detg. impurities in aliphatic hydrocarbons. There are certain heterogeneous systems (e. g., 0.4 cc. AcOH, 4.52 cc. C_6H_6, 5.00 cc. water) which are both foamy and nonfoamy, according to the different modes of shaking. This is due to the difference in the type of emulsion produced. 8 references. L. S.

The electric double layer and the stability of emulsions. E. J. W. Verwey. *Chem. Weekblad* **36**, 800–3(1939).—Elec. conditions in a colloidally dispersed solid and in an emulsion are contrasted. On a solid, the elec. double layer, potential of which depends on definite ions, forms a surface charge, all the potential drop occurring in the dispersing liquid. In an emulsion, the potential drop is distributed in a definite manner in both liquid phases. The function of the emulsifying agent is to produce in the double layer at the interface of the 2 liquids a condition resembling that of a double layer on the surface of a solid. A. H. Krappe

Electrophoresis in theory and practice. Arne Tiselius. *J. Franklin Inst.* **228**, 797–810(1939).—App. and technique for electrophoresis (scale and "schlieren" methods) are described, with a summary of results obtained by T. and others. Illustrated. Edward B. Sanigar

The different modes of retention of multimolecular films of stearic acid (Langmuir films). Line Denard. *J. chim. phys.* **36**, 216–17(1939).—*X* and *Y* films of stearic acid on polished Cr were obtained without varying the compn. of the aq. support but simply by modifying the superficial film pressure. The different forms of stearic acid characteristic of the cryst. state are found in 2 dimensions. Henry C. Thomas

Evaporation of built-up molecular films. S. J. Gregg and E. E. Widdowson. *Nature* **144**, 666–7(1939); cf. *C. A.* **33**, 8057⁹.—The condensation coeffs. for stearic and for arachidic acids detd. by evapn. in a high vacuum are both 0.01 ± 0.004. Mixed films of Ba stearate and stearic acid were analyzed by this method. The pH of the substrate and the Ba stearate contents of the film were, resp.: 3, 0%; 4, 5%; 5, 28%; 6, 76%; 7, 90%; 8, 100%. The compn. of the deposited film differs somewhat from that on the trough surface. G. M. P.

The viscosity of unimolecular surface films. Maurice Joly. *Kolloid-Z.* **89**, 26–35(1939).—A review. The app. is described and the theory outlined for the detn. of the viscosities of surface films by the rate of flow through a channel and by the rate of damping of the oscillations of a ring floating in the film. In addn. to the general features of surface films, the effect on viscosity of changes in the concn. of the films is discussed with reference to liquid, gaseous, mesomorphic and protein films. 42 references. W. B. Keighton, Jr.

Shapes of crystals formed in thin colloidal films. G. E. Viñar. *Anales asoc. quim. farm. Uruguay* **41**, 72–83 (1938)(Pub. 1939).—The arboreal form of the crystals formed in colloidal solns. is so common that certain authors have even suggested that all crystn. in such systems take this form or one very similar to it. That this is not generally true in thin colloidal films is shown experimentally. E. g., on mixing 2 solns. contg. 50% $(NH_4)_2SO_4$ and 10% Senegal gum, resp., short rod-like crystals were produced and on mixing 2 contg. 15% $Ba(NO_3)_2$ and 10% gelatin, resp., a lacework of row upon row of slender needle-like crystals interwoven at right angles with slender thread-like crystals was formed. The crystals from these solns. showed no tendency toward tree formation. Results with 20% NH_4Cl solns. alone and mixed with 10% gelatin or Senegal gum solns. showed that the nature of the crystalloid detd. the crystal form. Expts. with KCl, K_2SO_4, $KH(COO)_2$ and $K_4Fe(CN)_6$ in 10% gelatin solns. showed that increasing the complexity of the crystalloid increased the complexity of the crystals obtained. Varying the nature of the colloid (Senegal gum, gum arabic and agar-agar) in Al sulfate solns. resulted chiefly in changing the crystn. velocities with resulting larger or smaller crystals of the same form. The thickness of the colloidal film markedly changed the appearance of $Sr(NO_3)_2$ crystals in films formed after mixing 30% $Sr(NO_3)_2$ solns. with 10% gelatin solns. Impurities in the prepn. also changed the appearance. Iver Igelsrud

Studies in gelation and film formation. II. Studies in clay films. E. A. Hauser and D. S. Le Beau. *J. Phys. Chem.* **43**, 1037–48(1939); cf. *C. A.* **33**, 9141.—The formation of self-supporting coherent films of clay (Alsifilm) results from the lining up of the particles in the clay gel to give fibrillar interweaving cryst. aggregates. This structure accounts for the fact that films made up originally of small particles retain their water much more tenaciously than films made under identical conditions from fractions of coarse particle size; decreasing original particle size increases the capillary interstices in the film structure. Films dehydrated once at different temps. up to 550° take up from air (40% moisture content) the same amt. of water, irrespective of the original particle size. Films of H bentonite take up nearly twice as much water from moist air as films of natural bentonite. Clay films in the presence of electrolytes exhibit base exchange to a marked degree, the exchange being greater the smaller the size of the particles from which the film was made. Exchange of Na for K or Pb followed by heating the film to 110° decreases greatly the capacity for taking up water. This water resistance following base exchange results only with cations that form extremely sol. salts and whose apparent diams. are of the same order of magnitude as the spacing between opposite O atoms in the hexagonal Si-O sheets of the clay lattice. The cation of suitable dimensions serves to bind unit layer parcels in a way similar to that in mica. The structure of the films is discussed on the basis of x-ray analytical studies. Harry B. Weiser

A property of radiocolloids. Catherine Chamié and

Branca Edmée Marques. *Compt. rend.* **209**, 877–9 (1939); cf. *C. A.* **33**, 4868⁴.—Expts. are described in which solns. of Po in HNO_3 of varying concn. poured on paraffin were examd. photographically, showing that the percentage of Po deposited as colloidal aggregates on the paraffin from a strongly acid soln. thereof is a function of the content of Po in the soln., the percentage decreasing as the content increases. C. A. Silberrad

Active oxides and reactions of solid substances. CXVI. The transition of γ-aluminum oxide into α-aluminum oxide, and the effect of the presence of foreign gases on this transition. Gustav F. Hüttig and Georg Markus. *Kolloid-Z.* **88**, 274–88(1939); cf. *C. A.* **33**, 3973⁹.—The investigations described deal mainly with the solubilities and with the decompn. of prepns. belonging to the transition series $\gamma\text{-}Al_2O_3 \rightarrow \alpha\text{-}Al_2O_3$. The conditions detg. the soly. were systematically varied. As starting material Al oxyhydrate ($\gamma\text{-}Al_2O_3.xH_2O$) prepd. in a definite way was used and the temp. (t_1) and the duration (τ_1) of the preliminary heating of this material were varied. Thus 7 series of prepns. originated; their solubilities and decompn. were examd. In the detn. of soly., the quantities of the prepn. (a) and of the solvent (b), as well as the concn. of the solvent (c), also the temp. (t_2) and the duration (τ_2) of the soln. process were varied. HCl and $K_2S_2O_7$ were chosen as solvent and decompg. agent, resp. The effect exerted upon the course of the transition $\gamma\text{-}Al_2O_3 \rightarrow \alpha\text{-}Al_2O_3$ by foreign gases, characterized by solubilities, was studied on series of prepns. which were heated beforehand to a temp. t_1, not in the air but in the various streams of the dry gases. Under the conditions maintained during the detn. of the soly., the quantity dissolved is at least approx. proportional to the quantity (a) used for the soly. test. There also exists only a slight susceptibility of the quantity dissolved to variations in concn., temp (t_2) and the quantity (b) of the solvent used (HCl). The soly. decreases with the duration of the preliminary heating (τ_1), and it does so the quicker, the higher the temp. (t_1) of this heating. The decompn. tests, performed with the use of fused $K_2S_2O_7$, showed that at a const. quantity of $K_2S_2O_7$ and const. duration of the test, the quantities decompd. were approx. proportional to the weighed portion of the prepn. With increasing temp. of the preliminary heating, the decomposability sinks; this decline is particularly great when the temp. of the preliminary heating is raised from 950 to 1000°. However, there are also regions in which the increase in the temp. of the preliminary heating causes an increase of decomposability. As far as the properties of the prepns. made in the various gas streams are concerned, these foreign gases can be divided into 3 groups. Gases belonging to the 1st group (NO_2, CO_2, air, N_2 and SO_2) can be characterized as rather ineffective (only a slight affinity to Al_2O_3 can be attributed to all these gases). The prepns. show solubilities approx. equal those which characterize them when they are prepd. in an inert atm. of N. In contrast to this, the presence of the 3rd group of foreign gases (H_2O, HBr, SO_3 + air, HCl) causes a strong lowering of the solubilities. This group of gases consists of those that have a great affinity for Al_2O_3, an affinity which, under different conditions, would suffice for the formation of compds. (AlOOH, $AlBr_3$, $Al_2(SO_4)_3$, $AlCl_3$). The foreign gases of a 2nd group (NH_3, NO_2 + air, Cl_2) occupy a middle position between the gases of the 1st and the 3rd group, with regard to their catalytic effect upon the Al_2O_3 transitions as well as their affinity to Al_2O_3. 26 references. E. A. Ackermann

pH and the stability of (colloidal) powders. I. Essential notions of pH. J. Rouvillois. *Mém. artillerie franç.* **17**, 773–98(1938).—The pH detn. is widely used in a variety of chem. work, including research. It is more convenient and more precise than titration or colorimetric methods, and the range of units (0 to 14) expressing the results is small and readily interpreted. A physicochem. theory of pH is given. Subsequent articles will give results of applying pH methods to stability measurements on powders, comparing this method with titration and colorimetric methods. B. E. Anderson

The function and significance of rheology. S. Erk. *Kolloid-Z.* **89**, 208–11(1939).—The broad realm of rheology, which deals with the flow behavior of substances is outlined briefly. The fundamental distinction between the state (phase doctrine) or the flow behavior (rheology) of substances is illustrated by several examples. The significance of rheology lies for the most part in a rationalization of research. S. I. Aronovsky

Viscometric and osmometric measurements on nitrocelluloses. Kurt H. Meyer and E. Wolff. *Kolloid-Z.* **89**, 194–201(1939).—Viscometric and osmometric measurements were made on acetone and cyclohexanone solns. of nitrocellulose. The relation between relative viscosity and concn. in the system nitrocellulose–acetone is shown by the Fikentscher equation (*C. A.* **26**, 5414). The const., ("sp. viscosity"), of this equation, therefore, is suitable for the viscometric characterization of nitrocelluloses. The limiting viscosity, $\lim_{c=0}\left[\frac{\eta\ \text{spec.}}{c}\right]$, was also detd. The results of the viscosity and osmotic measurements of the nitrocellulose solns. are discussed in regard to Staudinger's "degree of polymerization." A graph showing the relation between sp. viscosity, limiting viscosity and relative viscosity is given. S. I. Aronovsky

Behavior of colloidal suspensions with electrolytes. E. A. Hauser and S. Hirshon. *J. Phys. Chem.* **43**, 1015–36(1939).—The effects of electrolytes on colloidal suspensions are discussed theoretically. Various samples contg. different percentages of a mixt. of carefully fractionated and dialyzed Fe_2O_3 and bentonite sols were prepd., and their viscosity behavior was studied with a rotating-cylinder viscometer. When the Fe_2O_3 sol is added to the bentonite sol the final equil. viscosity of the system goes through a first max. and decreases through a min., whence it goes through a second max. The first max. may be considered as the greatest gelation effect induced in the bentonite sol by the addn. of the Fe_2O_3 particles, and the second max., as the greatest gelation effect in the Fe_2O_3 sol as induced by the addn. of the bentonite particles. The explanation offered for these phenomena appears to correlate well with a great variety of existing exptl. data. The proposed theory may offer a new means of predicting the behavior of electrocratic (lyophobic) sols and a better understanding of the gelation and coagulation of electrocratic colloidal dispersions in general. S. I. Aronovsky

Stability of silver iodide sols in the presence of gelatin. I. R. Protas. *J. Phys. Chem.* (U. S. S. R.) **13**, 446–50 (1939).—The stability of *M*/400 to *M*/8000 AgI sols in the presence of 0.005% gelatin and at pH values of 3.5 to 9.7 (AcOH and NaOH) was detd. by means of the intensity of the light dispersed from the sols. The effects of the addns. of K, Ba, Th and NO_3 ions are shown graphically. The protective action of the gelatin with respect to AgI sols is detd. by both the charge of the lyophobic AgI sol and that of the gelatin, in analogy with the effects of adsorbed inorg. electrolytes. F. H. R.

A new method for the quantitative measurement of coagulation. H. A. Wannow. *Kolloid-Beihefte* **50**, 367–474(1939).—An optical kinetic method for the detn. of coagulation is described with a photocell sensitive to infrared light waves. The direct and indirect methods of measuring the coagulation point are discussed. The change in the transmission of light by the addn. of electrolytes in the coagulation range depends on the molarity and activity coeff. of the dominant ion, and results in S-curves. The point of inflection of such an S-curve presents a better-defined coagulation value than is obtained from the fixed value of permeability to light. The ultramicroscope particle counts and the curves for the transmission of light agree well. Methods for detg. the dependence of the coagulation value on the sol concn. of As_2S_3 and TiO_2 sols over a large concn. range gave results for As_2S_3 in good agreement with the Burton rule (B. and MacInnes, *C. A.* **16**, 1037): the coagulation value for univalent dominant ions decreases, that for multivalent ions increases, and the value for bivalent dominant ions assumes an intermediate position as the sol concn. is increased. At very low sol concns. the valency of the

coagulating ion has but little effect. The positively charged TiO_2 sol deviates from the Burton rule. The effects of various coagulating electrolytes on As_2S_3, MnO_2, mastic, humic acid, and $Fe(OH)_3$ sols showed no relation between coagulation value and the Büchner lyotropic nos. The coagulation of mastic and clay sols by the reversing electrolytes, $AlCl_3$ and $ThCl_4$, was investigated with this new method, and it was found that the H ion and colloidal $Th(OH)_4$, obtained by hydrolysis of the $ThCl_4$, tended partially to stabilize the mastic sol. In the coagulation of As_2S_3 sol by binary mixts. of electrolytes a typical antagonism was observed with the KCl-$MgCl_2$ and the KCl-$BaCl_2$ mixts., whereas a sensitization was established with the KCl-$LaCl_3$ and the $MgCl_2$-$LaCl_3$ mixts. The soln. of the As_2S_3 sols could also be followed by light-permeability measurements. An alkali such as NaOH affects an As_2S_3 sol in only one direction, colloid → mol., whereas Na_2CO_3 can affect both soln. and coagulation of the sol. This new method can be used to measure the change of state in milk and protein solns. The *coagulation of whole milk*, *skim milk*, and *Ca caseinate* by HCl, and the changes in the *fermentation of whole milk* were followed by this optical kinetic method. S. I. Aronovsky

Freezing of iron oxide hydrosols as affected by their constitution and mode of freezing. A. Lottermoser and G. Schmole. *Kolloid-Z.* **89**, 328–40(1939).—The sols were prepd. by the method of Graham, and their behavior on freezing is strongly influenced by their electrolyte content. If a sol, which is reversible on thawing, is dialyzed, it tends to become irreversible, though the irreversibility disappears on prolonged aging. In confirmation of observations of Lottermoser and Büchholz great reduction of electrolyte content tends to make sols irreversible on thawing, the degree of irreversibility being dependent not merely upon reduction in total Cl, but on the relation total Cl/ultra Cl, which changes on aging. As Langenscheidt (*C. A.* **26**, 3166) found, addn. of HCl reëstablishes reversibility, evidently by replenishing ultra Cl. Irreversible sols cloud even before freezing, and flocculation on freezing must be due to concn. changes in sol structure and not to changes induced by freezing. In irreversibly frozen sols part of the ultra Cl migrates inwardly, a reversal of the known relative increase of ultra Cl upon diln. with water. Evidently an equil. exists between the Cl (apart from that included in the colloid ions) which appears in the form of ultra and of compensating Cl. This equil. is disturbed by changes in amt. of hydrate water in the colloid ions; these changes occur swiftly. Another equil. exists between the total external or "free" Cl and that included in the colloid ions, which changes slowly and explains the slow irreversible/reversible effect above mentioned. In the light of present knowledge the behavior of a sol upon freezing depends upon the amt. of "free" Cl which can quickly shift in its ratio to compensating Cl. It is still unsettled why dialyzed sols when concd. by sepn. of ice tend to aggregate and flock, whereas nondialyzed sols like those here used do not. The degree of dialysis necessary to evoke irreversibility is also unsettled. Jerome Alexander

The action of supersonic waves on colloid phenomena. V. Influence on thixotropy. 2. Thixotropic systems of iron hydroxide. Naoyasu Sata and Nobuzo Naruse. *Kolloid-Z.* **89**, 341–4(1939); cf. *C. A.* **33**, 7172⁴.—Fe_2O_3 sols prepd. by Graham's method were used, and supersonic agitation exerted a marked effect on the setting time. The nature of the effect varied with the salt concn., there being a delay with smaller concns. and an acceleration with higher salt concns. The delay is due to destruction of a hydration layer of strongly hydrated particles; the acceleration is due to orientation of weakly hydrated nonspherical particles. Most thixotropic systems contain nonspherical particles which introduce particle form as a factor in addn. to aggregation and hydration. Jerome Alexander

Time of set of silica gels. IV. The effect of aldehydes and sugars over a pH range. L. A. Munro and J. A. Pearce. *Can. J. Research* **17B**, 404–8(1939); cf. *C. A.* **33**, 9090⁹.—The effects of a series of sugars, aldehydes and other substances on the time of set of silica gels were investigated over a pH range. Diacetone alc., propionaldehyde, rhamnose hydrate and xylose give curves similar to those previously obtained with the alcs. having a const. and equal effect at pH 7. The hexoses behave as a group whereas the disaccharides show divergent effects. Propionaldehyde and acetone give very similar curves. The implications of the results are discussed. J. W. S.

Highly polymerized compounds. CCXXXV. Polymer homogeneity, polydispersivity and polymolecularity. H. Staudinger. *Melliand Textilber.* **20**, 781–3(1939).—A review of recent work on macromol. compds. shows that the term polymer homogeneity should be applied to high-mol. compds. consisting of mols. of varying wt. built up in the same way from the same units. Such compds. of high mol. wt. are also polymolecular and yield polydisperse solns. Since compds. whose mols. are identical with respect to structure and mol. wt., e. g., a soap, may form in soln. colloidal particles of varying size, polydispersivity is a condition or state whereas polymer homogeneity and polymolecularity are properties of mols. J. W. Perry

Rupture of macromolecules with ultrasound. Gerhard Schmid and Otto Rommel. *Z. physik. Chem.* **A185**, 97–139(1939); cf. *C. A.* **34**, 3036.—Dil. solns. of polystyrene in benzene and toluene, polyvinyl acetate in Bu acetate, polyacrylic acid esters in Et acetate, nitrocellulose in acetone, Et-, Pr-, Bu-, iso-amyl, iso-Bu acetates and Et benzoate, and rubber were placed for definite time intervals (up to 240 min.) in a strong ultrasonic field of 284 kHz. and kept at a temp. detd. by the b. p. of the soln. This app. was described previously (cf. *C. A.* 32, 2800⁴). The viscosity of these solns. was markedly diminished, generally irreversably. This is interpreted as a depolymerization of the dissolved substance. It is shown that the ultrasonic vibrations directly affect the rupture of C–C bonds in the long-chain mols. The decompn. is more effective the longer the mol. chain. It is less at higher concns.; pastes or swollen gels are in general no longer affected. Also increasing pressure (15 atm.) in an O_2 atm. slackens the depolymerization of polystyrene in toluene and benzene, also of guncotton dissolved in Bu acetate. Theoretical considerations are presented as to the effect of sound vibrations on the stability of long polymerized chains. Victor R. Deitz

Micellar types of aqueous soap solutions. Joachim Stauff. *Kolloid-Z.* **89**, 224–33(1939); cf. *C. A.* 33, 6682⁷.—Photometric x-ray absorption curves were obtained on aq. solns. of Na tetradecyl sulfate and Na laurate, in various concns., at 20° and 75°. The absorption of x-rays by the soap solns. indicates the occurrence of large colloidal particles in 0.1 *N* solns. of Na tetradecyl sulfate and 0.2–0.25 *N* solns. of Na laurate. These particles are termed large micelles, to distinguish them from the smaller colloidal aggregates present in the solns. The structure of these large micelles was detd. to be *cryst. fluid*, indicating that they consist of one system, soap-water. According to the x-ray data, the water is located between the polar groups of the soap mol. These results reconcile the contradictions between the work and theories of Hartley (*C. A.* **31**, 1288⁷), on one hand, and the work of McBain (*C. A.* **25**, 1139) and Thiessen (*C. A.* 26, 896, 1498, 2908) on the other. Based on the magnitude or state of elec. charge on the particles, only one type of micelle exists, according to Hartley, whereas the size, form and space requirement of the particles indicate the existence of 2 different types of micelles. The structure of the large micelles is indicated by cond. min. as well as by the osmotic behavior of the soap solns. Forty-two references. S. I. Aronovsky

Colloid chemistry of the systems: soaps–cresol–water. IV. Viscosity of cresolated sodium stearate solutions in the presence of free fatty acids. E. Angelescu and V. Ciortan. *Kolloid-Z.* **89**, 47–54(1939); cf. *C. A.* 32, 4046⁶.—The viscosity of various concns. of Na stearate was detd. in the presence of excess amts. of stearic, palmitic and oleic acids and of *o*-, *m*-, and *p*-cresols, at 50° and 60°. In the absence of cresols, an excess of free acid

has no appreciable effect on the viscosity of the stearate soln. The 3 acids gave similar effects, the viscosity of the mixts. being equiv. to that of a stearate soln. of a concn. equal to the sum of the acid and salt present. The nature of the acid and temp. affect the viscosity of the stearate solns. only at sufficiently high concns. With stearate solns. above 0.2 *N* the acids increase the viscosity of the mixt. in the order: oleic < palmitic < stearic. The addn. of cresols leads to a sharp differentiation between the effects of the different acids and gives viscosity curves with marked max. Stearic acid caused a strong increase, and palmitic acid a smaller increase, in the viscosity max. of a Na stearate soln., whereas oleic acid lowers the viscosity max. of the soln. This difference in properties of the 3 acids is explained partly by the difference in length of their C chains. The different behaviors of these acids are apparent only in the region of maxt viscosity. In the horizontal portion of the curve these acids (in the presence of 5% cresol) have about the same effect on viscosity as an equal no. of Na stearate mols. Cresols tend to change the strongly lyophobic soap-acid complex to a lyophilic complex, and this tendency increases in the order: ortho < meta < para. S. I. Aronovsky

Discussion and interpretation of the thermodynamic properties, conductivity and diffusion of a typical colloidal electrolyte—laurylsulfonic acid in aqueous solution. Pierre Van Rysselberghe. *J. Phys. Chem.* **43**, 1049–61 (1939). —Data on f. p. and cond. of aq. solns. of laurylsulfonic acid were interpreted on the basis of an "av. micellar micelle." The size and elec. charge of the av. micelle vary with concn. in terms of which the soln. is considered as ideal, on the assumption that the sole constituents of the soln. at all concns. are free H ion and this "av. micelle." The Nernst formula for the diffusion coeff. of an unsym. electrolyte was applied to this av. micelle, and the main features of the exptl. diffusion were thereby reproduced. Some predictions were made regarding the variation of transport nos. of the H ion and the simple laurylsulfonate radical with concn. The possibility of decompg. the av. micelle into ionic and neutral micelles is discussed. S. I. Aronovsky

Organic substances that cause swelling. J. R. Katz and J. Seiberlich. *Rayon Textile Monthly* **21**, 82–3 (1940); cf. *C. A.* **33**, 2314,5.—Aq. solns. of thiocyanate, thiourea, chloral hydrate, etc., exert a more intensive swelling effect than pure water. The results are indicated of a research on the swelling action on mixts. of equal parts of potato starch, collagen, gelatin, cellulose, etc. It is concluded that only in a few special cases is the swelling action of one lyotropic substance improved by the addn. of another compd. of the same type. In most cases the swelling phenomenon produced by a lyotropic substance will be considerably reduced by the addn. of another lyotropic substance that has a different ion. W. H. Boynton

Elastic reactions of gels. Félix Michaud. *J. chim. phys.* **36**, 201–9(1939).—In a theoretical study of momentary equilibria in gels the effects of an external mech. or osmotic constraint are investigated. The results lead to a theory of cellular membranes. Henry C. Thomas

"Runge" figures and Liesegang rings on filter paper. Eugen Deiss. *Kolloid-Z.* **89**, 146–61(1939).—"Runge" figures (*C. A.* **29**, 2035[5]) were formed from a no. of salts on filter paper by displacement or by pptn. In one case it was found that, instead of the characteristic displacement or pptn. figures of Runge, rhythmic sepn. of the reaction products in the form of concentric rings was obtained. This occurred when a soln. of a manganous salt (with or without the addn. of K_2SO_4) was allowed to drop on filter paper which had been impregnated with K_2CrO_4 soln. and dried. The expt. was conducted at a relative humidity of 50%. On partial or complete substitution of the K_2CrO_4 by Na_2CrO_4 no rhythmic rings were formed. An increase in the atm. moisture above 50% relative humidity also hindered the ring formation. This case demonstrates "inner" rhythm of Liesegang rings and not the "outer" rhythm of Runge figures. The rhythmic ring formation was not obtained when a soln. of K_2CrO_4 was added to filter paper impregnated with a manganous salt. S. I. Aronovsky

Solubility of carbon dioxide in benzene at elevated pressure. Shen-Wu Wan and Barnett F. Dodge. *Ind. Eng. Chem.* **32**, 95–8(1940).—Values for mol. % of CO_2 in C_6H_6 (both liquid and gas phases) are shown graphically for pressures up to 95 atm. and for temps. of 30°, 40°, 50° and 60°, resp. Values of k in the equation $yP = kx$ (where y and x are the mol. fractions of CO_2 in gas and liquid phases, resp., and P is the total pressure in lb. per sq. in. abs.) are (for 0.1, 0.2, 0.3, 0.4, 0.5, 0.6 and 0.7 mol. fractions of CO_2 in the liquid, resp., for each temp. noted): 30°, 1240, 1230, 1208, 1190, 1169, 1102, 1045; 40°, 1420, 1430, 1440, 1395, 1360, 1303, 1255; 50°, 1670, 1650, 1605, 1605, 1588, 1535, 1492; 60°, 1860, 1918, 1940, 1935, 1910, 1840, 1742. Av. values of k are also given for approx. calcns. The present results differ considerably from those of Sander (*C. A.* **6**, 954). George Ayers

Solubility in liquids of gases from mixtures under pressure. Ya. D. Zel'venskiĭ. *J. Phys. Chem.* (U. S. S. R.) **13**, 514–27(1939).—Exptl. data on the soly. in H_2O of the components of the systems N_2–CO_2 and H_2–CO_2, at 25° and under pressures of 25 to 300 atm. are given. The presence of CO_2 decreases the soly. of N_2 and H_2 up to 21%; H_2 and N_2 decrease the soly. of CO_2 up to 4%. The energy of interaction of the gases in soln. is not over 110–125 cal. F. H. Rathmann

Thermodynamic relations between the dissociation pressure and the solubility of strong complex electrolytes. I. G. Ryss. *J. Phys. Chem.* (U. S. S. R.) **13**, 547–50 (1939).—Theoretical discussion of systems of the type Na_2SiF_6–$2NaF + SiF_4$. F. H. Rathmann

Investigation of the exchange between a metal and ions in solution by using radioactive indicators. B. V. Rollin. *J. Am. Chem. Soc.* **62**, 86–7(1940).—Expts. using radioactive silver show that exchange takes place between a soln. of Ag^+ ions and a surface of metallic Ag. In 2 hrs. an exchange of silver corresponding to 10 at. layers was found. The exchange was increased by a factor of 10 if the surface was pretreated with $NaNO_3$ soln.; these results are unexplained. The isotope was Ag^{108} having an 8-day half-life and was obtained by bombarding Pd with 8 m. e. v. deuterons. A. B. Garrett

Determination of transference numbers of ions in fused salts. Yu. V. Baĭmakov and S. P. Samusenko. *Trans. Leningrad Ind. Inst.* **1938**, No. 1, Sect. Met. No. 1, 3–26.—The literature is reviewed. Use of anode cells with an insol. anode is not recommended. The best app. is that which has 3 compartments connected with tubes not less than 2–3 mm. in diam. The selection of the diam. depends on current strength and sp. elec. cond. of the electrolyte. The study was limited to the system KCl–$PbCl_2$. B. Z. Kamich

Anomalous diffusion of quinone in salt solutions. Herbert Freundlich and Deodata Krüger. *J. Phys. Chem.* **43**, 981–8(1939).—When KCl or K_2SO_4 diffuses in an aq. soln. of quinone or succinic acid, there is a peculiar change in concn. known as "diffusion retrograde." The second solute increases in concn. on the salt side of the borderline, and decreases on the solute side. In cases like this, it is found that the soly. of the second solute is decreased by the presence of the salt (e. g., quinone by KCl). On the other hand, when the soly. of the second solute is increased by the presence of the salt (e. g., quinone by KNO_3), the concn. changes are in the opposite directions. J. H. Reedy

Surface-tension measurements to determine double salts in solution. Georges Arcay and Marcel Marcot. *Compt. rend.* **209**, 881–2(1939).—Measurements of the surface tension of mixed 0.2 *N* solns. of 2 salts forming a double salt (care being taken that the mixing is done drop by drop so that the proportion of the salts remains const., e. g., for a 2:1 mixture alternately 2 drops of one and 1 of the other should be added) show with KCl and $HgCl_2$ distinct min. for the double salts, i. e., for KCl.$2HgCl_2$, KCl.$HgCl_2$ and 2KCl.$HgCl_2$; and similarly for

NaCl and $HgCl_2$, though here the min. are less marked. C. A. Silberrad

Molecular interactions in solutions: effects on rotation of dipoles in an alternating field. Pierre Girard and Paul Abadie. *Compt. rend.* **209**, 874–7(1939).—Dispersion and absorption curves $((\epsilon' - \epsilon'')/(\epsilon_1 - \epsilon_0)$ and $\epsilon''/(\epsilon_1 - \epsilon_0)$ against λ) are plotted for radio frequencies (λ = 3–300 cm.) for PrOH with 40% of C_6H_6 and C_6H_{14} and compared with similar curves for pure PrOH. The differences in the curves for the mixed liquids and those for the pure PrOH are characteristic of the mixts. C. A. Silberrad

Water in nonaqueous solutions. W. J. V. Osterhout and J. W. Murray. *Science* **90**, 397–8(1939).—If increasing amts. of Cl_3CCO_2H are added to a 2-phase guaiacol-water system in equil. at 25° the concn. of water in the guaiacol phase steadily increases, whereas its activity in this phase decreases. Since the acid can attract both water and guaiacol it is able, when added in sufficient quantity, to make the 2 phases fuse into 1. These findings may be significant in *biol. systems*. Felix Saunders

Viscosity of the system ketones–organic acids. I. V. V. Udovendo. *J. Gen. Chem.* (U. S. S. R.) **9**, 1162–6(1939).—The viscosity and d. were detd. for binary systems contg. acetone and CCl_3CO_2H (at 35, 45, 55°), CH_2ClCO_2H (at 25, 35, 50°), HCO_2H (at 25, 35, 45°), AcOH (at 20, 30, 40°), $C_3H_7CO_2H$ (at 25, 35, 45°), resp. A chem. reaction occurs between acetone and the acids studied. Gertrude Berend

Modern conception of acids and bases. S. S. Israelstam. *J. S. African Chem. Inst.* **22**, 44–56(1939).—A survey of the modern theory of acids and bases in aq. solns. and in nonaq. solvents. A. B. Garrett

Magnetooptic study of neutralization. Fernand Gallais and Daniel Voigt. *Compt. rend.* **209**, 872–4(1939).—The magnetic rotation (ρ) of a mixt. of normal HCl and NaOH when plotted against compn. shows a decreasing value as neutralization is approached and a sharp min. at neutralization. This is more marked when instead of ρ the difference (Δ) between the actual ρ and that calcd. by the additivity law is similarly plotted. Δ increases with the concn. of the 2 solns. With H_2SO_4 there is very little effect on neutralization of the first H. In general, Δ is greater the stronger the acid. But HNO_3 and HCNS give anomalous results, owing probably, in the case of HNO_3, to change in structure and consequent diminution in the amt. of $(NO_3)^-$ ion, and in that of HCNS to a partial transformation of thiocyanic into isothiocyanic acid (cf. Gallais, *C. A.* **33**, 7231[1]). C. A. Silberrad

Error of a glass electrode in alkaline solutions as a function of temperature. V. A. Pchelin. *J. Phys. Chem.* (U. S. S. R.) **13**, 490–4(1939).—Exptl. data for the values of $\Delta\epsilon/\Delta$ pH are given for the H_2 and glass electrodes at temps. from 0 to 80° over pH values 1 to 12.7. Up to pH = 9.5 at 0–30°, 8 at 48.6°, and 6 at 59°, the error of the glass relative to the H_2 electrode is small and then increases rapidly with increasing pH. F. H. R.

pH measurements with new glass electrodes of highly conductive glass. K. Schwabe and O. Herdey, Jr. *Zellstoff u. Papier* **19**, 530–3, 567–70(1939).—The suitability of glass electrodes, made from the new highly conductive glass (*C. A.* **33**, 2371[3]), for pH measurements was studied. The shift in potential with changes in H-ion concn. does not follow the Nernst equation as closely in the new glass as it does with electrodes of the usual glass compn. (72% SiO_2, 6% CaO, 22% Na_2O). The pH displacement with the new glass electrodes is toward the alk. side, owing to the emission of alkali ions from the highly conductive glass. Temporary, inconst. variations in potential are obtained with this new electrode. S. I. Aronovsky

Equilibrium between valine and ammonium dimethyl pyruvate. R. Wurmser and S. Filitti-Wurmser. *Enzymologia* **7**, 161–4(1939)(in French).—The potential of the system, valine $\rightleftarrows$ dimethylpyruvate + NH_4 ion at pH 7 and 37° is $E_0 = -0.115 \pm 0.015$ v. when the ratio of the constituents is 1, provided that there is no appreciable amt. of the imino acid. Felix Saunders

Osmotic pressure, reduction-oxidation-potential, affinity. G. L. de Haas-Lorentz. *Chem. Weekblad* **36**, 782–5(1939).—An examn. of the equil. of 2 isolated systems in contact with one another, under application of the laws of thermodynamics leads to the establishment of series of differential equations and the expression of intensity parameters in the form of differential quotients. From these it is also possible to derive expressions for osmotic pressure, the reduction-oxidation-potential, and affinity. A. H. Krappe

Electrocapillary curves in nonaqueous solutions. I. Capillary-active organic cations in methanol. A. Murtazaev and M. Abramov. *J. Phys. Chem.* (U. S. S. R.) **13**, 350–2(1939).—Exptl. data are given for the electrocapillary curves of Hg in the presence of NH_4NO_3, $N(CH_3)_4I$, $N(C_2H_5)_4I$ and $N(CH_3)_3HCl$. The nature of the effect of the capillary-active substances is the same in MeOH as in H_2O; the activity of $N(C_2H_5)_4I$ is greater in MeOH than in H_2O. Although in aq. soln. the curves for these substances approach that for NH_4NO_3 far from the max., this is not true for MeOH solns. F. H. R.

Solutions of metallic cadmium in molten chlorides. S. Karpachev and A. Stromberg. *J. Phys. Chem.* (U. S. S. R.) **13**, 397–405(1939).—The potential of a C electrode with respect to solns. of metallic Cd in molten NaCl, KCl and $CdCl_2$ and their mixts. at temps. near 700° obeys the equation $E = a - \frac{2.3RT}{2F} \log C$. The soly. of at. Cd increases linearly from 0.042 wt. % in pure KCl to 2.05 in a 50 mol. % $CdCl_2$–KCl soln. F. H. Rathmann

Internal friction in molten salts as a function of concentration. A. G. Stromberg. *J. Phys. Chem.* (U. S. S. R.) **13**, 436–45(1939).—S. describes an app. more stable and simple than that of Harris (*C. A.* **28**, 3942[4]) and Hunter (*C. A.* **28**, 4553[4]) for detg. the rate of fall of a sphere in a volatile, colored, molten salt at high temps. From 270 to 450°, the coeff. of internal friction of 0.05 to 0.70 *N* solns. of AgI in HgI_2 is a linear function of the concn. The slopes or ratios η/η_0 for a 0.7 *N* soln. with respect to pure HgI_2 are 1.61 at 275°; 1.50, 300°; 1.32, 350°; 1.22, 400°; 1.20, 425°. For KCl in $SbCl_3$ soln. at 100°, η is linear from 0.009 to 0.5 *N*; the ratio $(\eta_{0.5}/\eta_0)$ is (0.0246/0.0171) = 1.41. Above 0.5 *N*, up to 1.91 *N*, η increases somewhat more rapidly. While the Falkenhagen electrostatic theory is applicable only up to KCl concns. of 1.6×10^{-5} *N* in $SbCl_3$ and 10^{-4} *N* in CH_3OH, the Einstein colloid soln. theory is applicable throughout most of the range of concns. studied. F. H. R.

Concluding remarks of the discussion with E. Janecke. Heterogeneous equilibrium in binary mixtures with vapor pressure maxima. R. Vogel. *Z. physik. Chem.* **A185**, 152(1939); cf. Janecke, *C. A.* **33**, 9106[1]. V. R. D.

Diffusion of hydrogen through iron at high pressures. P. S. Perminov and B. F. V'yunov. *Korroziya* **4**, No 3, 229–38(1938); *Khim. Referat. Zhur.* **2**, No. 3, 138 (1939).—Diffusion of H through Armco Fe depends on the size of the grains, the temp. (260–360°) and the pressure (300–1700 atm.). As a rule the velocity of diffusion is proportional to the square root of the pressure. Diffusion takes place through the grains of ferrite as well as along the surfaces of the grains. The velocity of diffusion through the intercryst. substance of the Armco Fe is greater than through the crystals. With an increase in the size of the grains the velocity of diffusion decreases, but with an increase of the pressure the effect of the size of the grains is decreased. W. R. Henn

Theory of crystal growth and the formation of crystal nuclei. I. N. Stranski and R. Kaishev. *Uspekhi Fiz. Nauk* **21**, 408–63(1939); cf. *C. A.* **33**, 3227[9].—The authors discuss, from both the thermodynamic and the statistical viewpoints, equilibria between two or three-dimensional nuclei and the gas or molten phase, simple homopolar and heteropolar crystals, kinetics and rate of liquid or crystal nuclei formation from supersatd. vapors or of a

gas from a superheated liquid, and the rate of polymorphic transformaion or recrystn. F. H. Rathmann

Kinetics of phase change. I. General theory. Melvin Avrami. *J. Chem. Phys.* **7**, 1103–12(1939).—The theory of the kinetics of phase change is developed with the experimentally supported assumptions that the new phase is nucleated by germ nuclei which already exist in the old phase, and whose no. can be altered by previous treatment. The d. of germ nuclei diminishes through activation of some of them to become growth nuclei for grains of the new phase, and ingestion of others by these growing grains The quant. relations between the d. of germ nuclei, growth nuclei, and transformed vol. are derived and expressed in terms of a characteristic time scale for any given substance and process. The geometry and kinetics of a crystal aggregate are studied from this point of view, and it is shown that there is strong evidence of the existence, for any given substance, of an isokinetic range of temps. and concns. in which the characteristic kinetics of phase change remains the same. The detn. of phase reaction kinetics is shown to depend upon the solution of a functional equation of a certain type. Some of the general properties of temp.-time and transformation-time curves, resp., are described and explained. G. M. Petty

The viscosity effect of the rate of solution of calcium carbonate in hydrochloric acid. Hitosi Tominaga, Hirosi Adzumi and Taro Isobe. *Bull. Chem. Soc. Japan* 14, 348–52(1939).—The reciprocal of the first-order rate const. is a linear function of the viscosity, and also of the reciprocal of the rotational velocity of the $CaCO_3$ disk: The change of viscosity with temp. must be considered in calcg. the energy of activation. S. B. Stone

Oxidation of solutions of ferrous chloride in alcohols. James R. Pound. *J. Phys. Chem.* **43**, 969–80(1939).—Alc. solns. of $FeCl_2$ are oxidized by air much more rapidly than aq. solns. The action is bimol. with respect to the Fe^{++} concn., and the rate of oxidation increases with the mol. wt. of the alc. Water and acids decrease the speed of oxidation. The O consumed in oxidizing alc. solns is greater than expected, probably because of the oxidation of the alcs. to aldehydes. The rate of oxidation is also influenced by the presence of light, H_2O, Hg and acid. Elec. conds. increase during oxidation. J. H. Reedy

Velocity of oxidation of CoO to Co_3O_4. Germaine Chauvenet. *Compt. rend.* **209**, 886–7(1939); cf. *C. A.* 32, 8322[4].—In similar fashion the oxidation at 500–750° to Co_3O_4 of polished pieces of CoO formed by preliminary heating in O_2 of disks of Co 2 × 5 mm. was examd. Results confirm the parabolic law as with metals and give the energy of activation as 23,950 cal., and the wt. of O_2 fixed at temp T, and pressure 760 mm. in time t by s sq. cm. CoO as $571se^{-11975/T}\sqrt{t}$. C. A. S.

Mechanism of oxidation of organic compounds by means of selenious anhydride. V. Kinetics in the oxidation of aldehydes. N. N. Mel'nikov and M. S. Rokitskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 1158–61(1939); cf. *C. A.* 33, 4194[2].—The oxidation of CH_3CHO, C_2H_5CHO, C_3H_7CHO, $C_6H_{13}CHO$, $(CH_3)_2CHCHO$ and $(CH_3)_2CH$-CH_2CHO by means of H_2SeO_3 in 75% AcOH was studied and the velocity of this reaction detd. The results show that the oxidation velocity decreases with increasing mol. wt. with the exception of CH_3CHO where the reaction const. is considerably smaller than that of C_2H_5CHO. This is explained by the easy polymerization of CH_3CHO in acid medium. The reaction const. is decreased also in the iso compds. as compared with the normal compds. Thus the reaction const. of C_3H_7CHO is 7.96×10^{-5}, and of $(CH_3)_2CHCHO$ 1.22×10^{-5}. G. Berend

The reaction of hydrogen and deuterium atoms with propane. E. W. R. Steacie and N. A. D. Parlee. *Can. J. Research* **17B**, 371–84(1939); cf. *C. A.* **30**, 6648[5].—The reaction of H atoms with C_3H_8 was investigated over the temp. range 30° to 250° by the Wood-Bonhoeffer method. The products are solely CH_4 at low temps., and CH_4, C_2H_6 and C_2H_4 at higher temps. It is concluded that the results can be explained only by the assumption that the reaction $H + C_2H_8 \rightarrow 2CH_3$ is of importance. The bearing of this on the Rice-Herzfeld mechanism (*C. A.* **33**, 8090[4]) is discussed. The activation energy of the reaction is 10 ± 2 kg.-cal. The main steps in the postulated mechanism are: Primary reaction $H + C_3H_8 \rightarrow C_3H_7 + H_2$. Secondary reactions at low temps. $H + C_3H_7 \rightarrow CH_3 + C_2H_5$; $H + C_2H_5 \rightarrow 2CH_3$; $CH_3 + H \rightarrow CH_4$. Addnl. secondary reactions at high temps. $C_3H_7 \rightarrow C_2H_4 + CH_3$; $2CH_3 \rightarrow C_2H_6$; $H + C_2H_4 \rightarrow C_2H_5$; $H + C_2H_5 \rightarrow C_2H_6$; $H_2 + C_2H_5 \rightarrow C_2H_6 + H$. The reaction of deuterium atoms with C_2H_8 was also investigated. It was found that the CH_4 and C_2H_5 produced were highly deuterized, while the C_3H_8 was not appreciably exchanged. J. W. Shipley

Kinetics of bimolecular reactions in solutions. V. A. Hol'tsshmidt and N. K. Vorob'ev. *J. Phys. Chem.* (U. S. S. R.) **13**, 473–82(1939).—The values of the bimol. reaction consts. $K \times 10^4$/min. were found to be: *m*-chlorodimethylaniline + allyl bromide in MeOH at 30°, 25.3; at 38°, 50.8; in EtOH at 30°, 28.9; at 40°, 65.4; *p*-bromodimethylaniline + allyl bromide in benzyl alc. at 16°, 50.5; at 23°, 87.2; pyridine + benzyl chloride in nitrobenzene at 30°, 2.20; at 38°, 2.22; dimethylaniline + benzyl chloride in MeOH at 29°, 21.3; at 38°, 43.7. From these and other exptl. data H. and V. calc. the values of K 30°, log B and E in the Arrhenius equation $K = Be^{-E/RT}$ for various reactions and solvents. From these data it is concluded that the values of K for various substituted anilines in the same solvent increase in the order Br < Cl < H < CH_3; for the quinolines, quinoline < *m*-toluquinoline < *p*-toluquinoline; and for the various halides in the order: benzyl chloride < allyl bromide < benzyl bromide. For the solvents, the values of K increase with increasing values of the dipolar moments; $K_{acetone} < K_{acetophenone} < K_{nitrobenzene}$; $K_{EtOH} < K_{MeOH} < K_{benzyl\ alc.}$ A theory is developed for the part played by the solvent, and an equation is derived for the pre-exponential factor (cf. Wynne-Jones and Eyring, *C. A.* **29**, 6491[2]). F. H. Rathmann

Velocity of formation of *m*-nitroaniline hydrochloride. Dora Markowska. *Compt. rend.* **209**, 879–81(1939).—In a fashion similar to that of *C. A.* **33**, 5732[2,3], the rate of formation of *m*-nitroaniline-HCl (d. 1.468) by the action of gaseous HCl on powdered *m*-nitroaniline was detd. The amt. m transformed in time t is $F(m) \equiv 5.3215 - (1-m)^{2/3} - 4.3215(1 + 0.2314m)^{2/3} = Kt/e_0^2$, where K is a const. dependent on the phys. conditions, and e_0 is the av. thickness of the grains of the *m*-nitroaniline. C. A. Silberrad

Liquid-phase reactions at high pressures. V. The polymerization of cyclopentadiene and α-dicyclopentadiene. B. Raistrick, R. H. Sapiro and D. M. Newitt. *J. Chem. Soc.* **1939**, 1761–9; cf. *C. A.* **32**, 8376[2].—The polymerization of pure liquid cyclopentadiene under pressure, up to 5000 atm., at temps. from 0° to 40°, proceeds in 3 stages: (*a*) dimerization to α-dicyclopentadiene, (*b*) production of higher polymers, and (*c*) an explosive disruptive reaction, occurring within definite pressure limits at each temp., accompanied by the formation of a carbonaceous residue and much gas. The specific reaction rates (k), at various temps., and the energies of activation (E) for the bimol. reaction (*b*) were detd. at a no. of pressures; both the A and E terms of the rate equation $k = Ae^{-E/RT}$ increase with increasing pressure, E varying with log A in a linear manner. The substances formed in (*b*), and those obtained by subjecting α-dicyclopentadiene to pressure at 130°, are related to those resulting from heat polymerization. **VI. The explosive decomposition of cyclopentadiene.** *Ibid.* 1770–3.—The effect of temp., diam. and material of the reaction tube and of the presence of a diluent on the explosive decompn. of cyclopentadiene (cf. above) was studied. The lower crit. pressure necessary for the reaction to occur decreases with increasing temp. (between 13° and 40°) and with increasing diam. of the tube. This pressure is greater in a stainless steel tube than in one of glass, but pieces of glass produce no catalytic effect in the steel tube. The addn.

of n-C_7H_{16}, AcOEt or AcOH as diluent increases the lower crit. pressure, the effect increasing in the order given. The gaseous product of the reaction is a mixt. of 92% CH_4 and 8% H_2. The carbonaceous solid has an x-ray structure similar to low-temp. coke obtained at 550–600°. The existence of an induction period and of crit. pressure limits dependent on the surface/vol. ratio of the reaction vessel suggests a chain mechanism, the chains being broken at the walls. The different results obtained in steel and glass tubes are attributed to the higher heat cond. of the former, with consequent reduction in the self-heating of the system. S. Glasstone

Velocities of the hydrolysis of ethers. Roman Skrabal. *Z. physik. Chem.* **A185**, 81–96(1939).—The effect of the following different alkyl ethers on their velocities of hydrolysis was investigated: vinylethyl, vinylisopropyl, vinylallyl, diallyl, ethylallyl and isopropylallyl ethers. The reacting solns. at 15°, 25° or 35° all contained 0.0909 *M* AcOH and 0.00909 *M* Na acetate per l., i. e. $(H^+) = 1.85 \times 10^{-4}$. The results are discussed from the viewpoint of the reaction mechanism, 2 factors being emphasized: a factor, μ, corresponding to a displacement of the equil., another factor which takes into account the change of the decompn. velocity of the reaction complexes. Victor R. Deitz

Relations between electrostatic potentials and reaction velocities. H. O. Jenkins. *J. Chem. Soc.* **1939**, 1780–4; cf. *C. A.* **33**, 8478⁴.—The energy of activation in the hydrolysis of a series of benzoic esters, in the benzoylation of amines and in the formation of quaternary ammonium salts is a linear function of the electrostatic potential produced by a substituent in the benzene ring at the C-atom to which the reacting group is attached. The slope of the line is approx. equal to Ne, where N is the Avogadro no. and e is the electronic charge; this suggests that the change in the activation energy is due to the work done in bringing up a reacting ion against the dipole field of the mol. being attacked. In the acid hydrolysis of halogen-substituted benzoic acids and benzyl chlorides, and in the reaction of the latter with KI, a linear relation exists between the potential produced by the substituent and the specific rate const. The fact that *m*-compds. are exceptional is interpreted as indicating that the inductive and mesomeric effects of the halogens are proportional. S. Glasstone

Chain length and chain-ending processes in acetaldehyde decomposition. Milton Burton, H. Austin Taylor and Thomas W. Davis. *J. Chem. Phys.* **7**, 1080–5(1939); cf. *C. A.* **33**, 1217⁵, 5743⁴.—The C-C bond strength in AcH is probably less than a previously postulated value of 93 kg.-cal. and may be as low as the 75 kg.-cal. value calcd. by Grahame. The chain-ending processes in the pyrolysis, in the MeN:NMe-induced decompn., and in the photolysis of AcH are all bimol. but it is clear that the processes in the second and the third decompns. cannot be identical. The uncertainty of the process in the pyrolysis introduces an uncertainty into Grahame's calcn. In any event, the process is not the combination of Me radicals in the gas phase to yield C_2H_6. In the photolysis (and perhaps in the pyrolysis) HCO seems to be involved in the chain-ending reaction. In the induced decompn. MeCO seems to be concerned. The recombination of Me radicals as a wall reaction may occur in packed vessels. Activation energies of the various reactions are discussed. G. M. Petty

Kinetics of the Cannizzaro reaction. A. Eitel and G. Lock. *Monatsh.* **72**, 392–409; *Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIb, **148**, 90–107(1939).—For detg. the reaction velocity consts. of the Cannizzaro reaction for aromatic aldehydes, a new method was developed, with 50% aq. dioxane as the solvent. The decrease in the alkali concn. is detd. by titration, the aldehyde concn. by weighing as the 2,4-dinitrophenylhydrazone. The reaction with BzH is established as trimol. The investigation was made with BzH and the 3 Cl derivs. The Cl atom increases the reaction velocity in all positions. The consts. for BzH and the *o*-, *m*- and *p*-Cl derivs. are: 60° 7.15×10^{-3}, 2.93×10^{-3}, 2.60×10^{-1}, 6.03×10^{-2}; 80° 1.75×10^{-2}, 6.05×10^{-2}, 4.95×10^{-1}, 1.18×10^{-1}; 100° 3.70×10^{-2}, 1.14×10^{-1}, 8.45×10^{-1}, 2.14×10^{-1}. C. J. West

Theory of the Cannizzaro reaction. A. Eitel and G. Lock. *Monatsh.* **72**, 410–16; *Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIb, **148**, 108–14(1939).—The possible reactions are discussed. C. J. West

An easily arranged periodic action. E. E. Wark and I. W. Wark. *Nature* **144**, 833(1939).—A lecture expt. A Pb sheet is amalgamated with Hg. While still fluid a drop of concd. HNO_3 is placed on it. After about 1 min., gas evolution occurs for a fraction of a sec., followed by quiescence, with a cycle of about 1 sec. This continues for some min., until $Pb(NO_3)_2$ crystallizes out. Impure lead causes shorter cycles; weak acid causes longer cycles. Pb dissolves, liberating oxides of N. G. M. Petty

Acid catalysis in nonaqueous solvents. VIII. The rearrangement of *n*-chloroacetanilide in chlorobenzene solution at 100°. R. P. Bell and P. V. Danckwerts. *J. Chem. Soc.* **1939**, 1774–6; cf. *C. A.* **33**, 8482⁶.—The catalytic effect of chloroacetic, dichloroacetic, phenylacetic, and *o*- and *m*-nitrobenzoic acids on the rearrangement of *n*-chloroacetanilide into *o*- and *p*-chloroacetanilide in PhCl soln. at 100° shows that under these conditions the reaction is subject to general acid catalysis. The Brønsted relation $k = GK^x$, where k is the specific reaction rate, K the dissocn. const. of the catalyzing acid, and G and x are consts., is approx. obeyed. The reactions are strongly autocatalytic, and this effect is attributed to the formation of the powerful catalyst HCl by a side reaction between the reactant and the product. S. Glasstone

Acid-base catalysis in the depolymerization of dimeric glycolaldehyde. R. P. Bell and J. P. H. Hirst. *J. Chem. Soc.* **1939**, 1777–80.—The depolymerization of dimeric glycolaldehyde is catalyzed by both acids and bases in aq. soln. The reaction bears a general resemblance to the corresponding depolymerization of dihydroxyacetone (cf. Bell and Baughan, *C. A.* **32**, 4059³). The Brønsted equation, relating the specific reaction rate to the dissocn. const. of the catalyzing acid or base, is applicable. A new form of *micro-dilatometer*, which requires about 1 cc. of liquid, is used for the measurement of reaction velocity. S. Glasstone

Mechanism in the acid-catalyzed dimerization of anethole. Weldon G. Brown and Alex H. Widiger. *J. Am. Chem. Soc.* **62**, 115–16(1940).—The dimerization of anethole in a partly deuterated medium of CH_3OH and HCl is accompanied by a slow H exchange reaction of the monomer. The dimer contains no more deuterium than can be accounted for as a result of this exchange. It is difficult to find any support in these data for the Whitmore mechanism (cf. *C. A.* **28**, 1327⁹) involving an intermediate carbonium ion (or addn. compd.) in which the equivalence of the newly acquired H atom with H atoms previously present on the same C is to be assumed. A. B. Garrett

Oxidation of solutions of ferrous salts. James R. Pound. *J. Phys. Chem.* **43**, 955–67(1939).—The oxidation of solns. of $FeSO_4$ by air or O is accelerated by the presence of H_3PO_4 and HCl, but H_2SO_4 has little effect. The action of H_3PO_4 seems to be mainly catalytic. Low concns. of HNO_3 have little effect, but above 0.5 *M* the action becomes rapid. Mixed HNO_3 and HCl have no effect, if dil. Oxides of N accelerate the action. Neutral solns. are oxidized more rapidly than acid solns., and salts of weak acids more rapidly than strong acids. However, the addn. of neutral salts to acid solns. makes little difference in the speed. The formation of a ppt. of basic salt is accompanied by high rate of oxidation. In general, the rate of oxidation varies as the square of the concn. of the Fe^{++} salt. Oxidation of $Fe_3(PO_4)_2$ is very rapid, but is repressed by addn. of free H_3PO_4. Addn. of dil. solns. of H_2SO_4, HCl and HNO_3 also repress oxidation to a considerable degree. H_3BO_3 and $C_2H_4(COOH)_2$ also decrease oxidation slightly. Fe^{+++} salts are reduced by citric and oxalic acids in the presence of light, the amt. of reduction varying with the concns. of the acids.

H_2SO_4 inhibits this reduction, and H_3PO_4 accelerates it. In the dark, oxalic and citric acids reduce Fe^{+++} solns. slightly, if at all. In general, oxidation is least in the presence of low concns. of strong oxidizing acids, such as H_2SO_4 and HCl. No explanation is given for these effects. J. H. Reedy

Effect of gaseous additions on the disintegration of carbon monoxide. W. Baukloh and E. Spetzler. *Arch. Eisenhüttenw.* **13**, 223–6(1939).—The disintegration of C according to $2CO \rightleftharpoons C + CO_2$ is under ordinary conditions only very slight if no catalysts are present but even with metallic catalysts, as metallic Fe, Ni and oxides, it is not of much practical importance, e. g., for the destruction of Fe ores. The investigation of the effect of CO_2, N, H and water vapor in CO showed that disintegration takes place only in presence of metallic Fe. Presence of H produces at higher temps. a strong acceleration of the disintegration and is due mainly to chem. reaction at the surface of the substance. Water vapor suppresses C sepn., as it hinders the reduction of the Fe oxide. The better effect of H is ascribed to the ability of H to form a catalytically effective Fe lattice. For the operation of a blast furnace it is found that the range of 400–650° is particularly harmful, as in it C is pptd. instead of leaving as CO in the gas. M. Hartenheim

The relative effect of inhibitants on adsorption and on catalytic activity. II. Edward B. Maxted and Herbert C. Evans. *J. Chem. Soc.* **1939**, 1750–4; cf. *C. A.* **33**, 2101⁴.—The effect of H_2S on the poisoning of Pt black for the catalytic hydrogenation of crotonic acid runs parallel to the decrease in the rate of adsorption of H_2 by the same catalyst. A sharp change in the slope of the plot of the poison content of the Pt against the adsorption velocity or catalytic activity suggests that there are 2 types of adsorption on the Pt surface. S. Glasstone

Active substances. XLI. Characteristics of the change from amorphous ferric hydroxide to α-ferric oxide by adsorption and catalytic measurements. R. Fricke and H. Wiedmann. *Kolloid-Z.* **89**, 178–84(1939); cf. *C. A.* **34**, 1⁹⁶. The active α-Fe_2O_3 obtained by dehydration of amorphous $Fe(OH)_3$ at various temps. was investigated. Measurements were made on CO_2 adsorption, heat of adsorption of the CO_2, H_2O catalysis with change in concn. and temp. (values were based on apparent reaction order, heats of activation and reaction consts.), and the hygroscopic nature of the material. W. George Parks

Vapor pressures of some salts at high temperatures. I. I. Naryshkin. *J. Phys. Chem.* (U. S. S. R.) **13**, 528–33(1939).—From the exptl. data on the vapor pressures at temps. from 750 to 1000°, the values of A and B in the August equation, $\log p = -(A/T) + B$, are: 8810.6, 7.982 for NaCl; 8133.0, 7.580 for KCl; 9756.0, 8.463 for KF; 11387.7, 8.654 for NaF; and 5000, 4.35 for AlF_3. The heats of evapn. and the extrapolated b. ps. are: NaCl, 40.2 Cal., 1454°; KCl, 37.2, 1457; KF, 44.6, 1473; NaF, 51.9, 1702; AlF_3, 59.0, (sublimes). These values are fairly close to the av. values of other workers. F. H. Rathmann

Distribution of radium D between crystals and solutions of $Ba(IO_3)_2$. A. Polesitskii. *Acta Physicochim. U. R. S. S.* **8**, 864–8(1938); cf. *C. A.* **33**, 3654⁴.—Measurements of the distribution in the presence and absence of $Ca(NO_3)_2$ in the solns. are in agreement with Ratner's thermodynamic theory (*C. A.* **28**, 700²), as found previously for Ra. B. C. P. A.

The system isopropyl ether–isopropanol. Vapor-liquid equilibrium. H. C. Miller and Harding Bliss. *Ind. Eng. Chem.* **32**, 123–5(1940).—The vapor-liquid equil. curve is given. Joseph H. Wells

Phase equilibria in hydrocarbon systems. The propane n-butane system in the critical region. C. N. Nysewander, B. H. Sage and W. N. Lacey. *Ind. Eng. Chem.* **32**, 118–23(1940).—The volumetric and phase behavior of 6 mixts. of propane and n-butane were investigated throughout the two-phase region at temps. above 160°F. From these data the sp. vols. and the compns. of coexisting phases of the system were calcd. Joseph H. Wells

Existence of hydrates of a definite chemical composition in the liquid phase. I. The systems $Na_2S_2O_3$–H_2O and $Ca(NO_3)_2$–H_2O. B. V. Bak. *J. Phys. Chem.* (U. S. S. R.) **13**, 534–40(1939).—From exptl. data on the viscosities and elec. conds. of $Na_2S_2O_3$ and $Ca(NO_3)_2$ solns. contg. 0–77% of salt, at temps. from 20 to 80°, minima are found in the isotherms for the sp. conds., max. in their temp. coeffs., and max. in the temp. coeffs. of the viscosities corresponding to the hydrates $Na_2S_2O_3.5H_2O$ and $Ca(NO_3)_2.3H_2O$. Below approx. 50° $Ca(NO_3)_2.4H_2O$ is also stable. F. H. Rathmann

Electroconductivity of the molten potassium chloride–magnesium chloride system in the region of the possible existence of the compound $(KCl)_3.MgCl_2$. A. A. Shcherbakov and B. F. Markov. *J. Phys. Chem.* (U. S. S. R.) **13**, 353–5(1939).—Between 27 and 37 mole % $MgCl_2$ and 600–800°, the cond. isotherms show a discontinuity and the temp. coeffs. a max. at 33–34% $MgCl_2$. F. H. R.

Polytherm of the three-component system KCl–KH_2PO_4–H_2O at temperatures from −10.8 to +35°. V. A. Polosin and M. I. Shakhparonov. *J. Phys. Chem.* (U. S. S. R) **13**, 541–6(1939).—Data on the system over 5° intervals are given. The polytherm of the binary system KCl–H_2O shows a break at +22.2° for 26.2% KCl. On addn. of KH_2PO_4, the temp. of the polymorphic transformation of KCl decreases from 22.2 to 12.5°. The triple eutectic point lies at −10.8°, 18.84% KCl, 2.31% KH_2PO_4, a triple point at 22.6% KCl and 3.8% KH_2PO_4. KCl has a strong salting-out effect on KH_2PO_4. The system KCl–KH_2PO_4–H_2O forms no double compds. in the range studied but solid solns. of KH_2PO_4 in KCl are not excluded. F. H. Rathmann

The partial vapor pressures of water and ammonia from the system water–phosphoric acid–ammonia. Clayton S. Huey and H. V. Tartar. *J. Am. Chem. Soc.* **62**, 26–32(1940).—The partial pressures of NH_3 and H_2O were measured at 25° from solns. of H_3PO_4 contg. various amts. of NH_3 and from solns. of $(NH_4)_2HPO_4$ of varying molality. The hydrolysis const. of $(NH_4)_2HPO_4$ was found to be 8.87×10^{-3}. The dissocn. pressures of NH_3 and H_2O for the reaction $(NH_4)_2PO_4.3H_2O_{(s)} \rightleftharpoons (NH_4)_2HPO_{4(s)} + 3H_2O_{(g)} + NH_{3(g)}$ were measured over the temp. range from 25 to 50°. From these data K_p, $\Delta F°$, ΔS and ΔH were computed. A. B. Garrett

Intersection of the tie-lines in diagrams of three-component systems. D. Tarasenkov and I. Paulsen. *Acta Physicochim. U. R. S. S.* **11**, 75–86(1939)(in English).—Ternary diagrams are given for the systems EtOH–benzene–H_2O, EtOH–toluene–H_2O, EtOH–cyclohexane–H_2O, AcOH–benzene–H_2O, AcOH–$CHCl_3$–H_2O, at 20 and 25°. All the extensions of the tie-lines of any given system intersect in a single point. The tie-lines are given by equations of the type, $X(Y_1 - Y_2) + X_1(Y_2 - Y) + X_2(Y - Y_1) = 0$, where X_1 and Y_1, X_2 and Y_2 are the coördinates of the conjugate solns. F. H. Rathmann

Tie lines in two-liquid-phase systems. A. V. Brancker, T. G. Hunter and A. W. Nash. *Ind. Eng. Chem., Anal. Ed.* **12**, 35–7(1940).—A method is proposed for obtaining complete tie-line data for ternary systems having one pair of nonconsolute components forming 2 liquid phases. For the system toluene–acetic acid–water the wt. percentage of toluene in one liquid phase is plotted against the wt. percentage of water in the other liquid phase. By using a variable ordinate the tie-line curve is made to plot as a straight line. Thirty other ternary systems plot straight tie-line curves when this coördinate system is used. To obtain the tie-line curve for any other similar ternary system it is only necessary experimentally to det. 2 tie-lines. **Tie lines in ternary liquid systems.** Irvin Bachman. *Ibid.*, 38–9.—A plot of the ratio of the wt. percentage of nonconsolute A in the A-rich layer to wt. percentage of nonconsolute B in the B-rich layer is a straight line. Therefore from 2 experimentally detd. tie-lines and the equil. curve one may derive the compns. of any pair of conjugate solns. W. B. Keighton, Jr.

Defect lattices in some ternary alloys. H. Lipson and A. Taylor. *Proc. Roy. Soc.* (London) **A173**, 232–7 (1939).—In the Ni-Al system the soln. of Al in β-NiAl

structure is accompanied by omission of some Ni atoms from some points of the lattice. In the Cu–Ni–Al system the omission of atoms begins at a line of const. ratio of valency electrons to atoms. These results are accounted for by electrons in the Brillouin zone. If electrons fill the zone to a given energy level, the no. of electrons per unit cell should be const. This latter is true for the Ni–Al system. In the Cu–Ni–Al system the no. of electrons in the zone increases as Cu is added. 7 references. J. N. Lynn

System butyl magnesium bromide–magnesium bromide–ethyl ether. W. E. Doering and C. R. Noller. *J. Am. Chem. Soc.* **61**, 3436–7(1939).—A study of the system BuMgBr–$MgBr_2$–Et_2O shows that BuMgBr.$2Et_2O$ greatly modifies the soly. of $MgBr_2.2Et_2O$ in Et_2O and that the mutual soly. of the 2 dietherates is greater than their soly. in Et_2O. Whereas $MgBr_2.2Et_2O$ and Et_2O form homogeneous solns. at 25° only when the concn. of the dietherate is greater than 73% or less than 5.5%, if the total concn. of BuMgBr.$2Et_2O$ is greater than approx. 23% the ratio of the $MgBr_2.2Et_2O$ to the Et_2O may be any value without the sepn. into 2 phases; when sepn. into 2 phases does occur, the concn. of the BuMgBr.$2Et_2O$ is always greater in the lower layer than in the upper layer These 2 results indicate that the mutual soly. of the 2 dietherates is greater than their soly. in Et_2O. C. J. West

System of alkali oxides–CaO–Al_2O_3–SiO_2–CO_2. IX. The reaction behavior of different SiO_2 modifications. Carl Kröger and Werner Graeser. *Z. anorg. allgem. Chem.* **242**, 393–405(1939); cf. *C. A.* **33**, 6696[8].—With Li_2CO_3, cristobalite, like quartz, forms Li_2SiO_3. No $CaSiO_3$ or $CaSiO_4$ forms (as in the case of quartz) on the heating of $CaCO_3$ with cristobalite but only a soln. of CaO in SiO_2. $Na_2Ca(CO_3)_2$, formed by heating a mixt. of Na_2CO_3 and $CaCO_3$ in a Pt crucible in a stream of CO_2 at 820°, reacts with cristobalite according to the equation $3[Na_2Ca(CO_3)_2] + 6(SiO_2)_{cryst} = [Na_2O.2CaO.3SiO_2] + [2Na_2O.CaO.3SiO_2] + 6CO_2$. Vapor pressure-temp. curves for these systems as well as for the systems K_2CO_3 with cristobalite, tridymite and pptd. SiO_2 are presented. H. A. Frediani

The heat capacity of nickel oxide from 68 to 298°K. and the thermodynamic properties of the oxide. Harry Seltz, Bernard J. DeWitt and Hugh J. McDonald. *J. Am. Chem. Soc.* **62**, 88–9(1940).—The heat capacity of NiO was measured from 68 to 298°K. and the entropy and free energy of formation of the oxide calcd. The entropy of the oxide is 8.36 e. u. ± 0.1 e. u. The contribution of the Debye function to the entropy is 0.648 e. u. at 68°K., whereas the contribution of the Einstein function is less than the exptl. error. The value of $\Delta F°_{298.1}$ was calcd. with the aid of Bichowsky and Rossini's value of $\Delta H_{298.1}$ = 58,400 cal. This value and the entropy of formation, $\Delta S_{298.1} = -18.00$, gives $\Delta F°_{298.1} = -53{,}034$ cal. A. B. Garrett

The heat of dissociation of carnallite melts. W. D. Treadwell and A. Cohen. *Helv. Chim. Acta* **22**, 1341–8 (1939); cf. *C. A.* **33**, 6696[1].—The e. m. f. of chlorine-magnesium cells was measured in the temp. range 550–750° with pure $MgCl_2$ and carnallite as electrolytes. Satisfying agreement was found with the values calcd. from the equil. measurements. From the relatively great variation of the values of the e. m. f. by addn. of KCl the existence of chlorine-magnesium complexes could be concluded. Robert Simha

Heat of formation of AgF_2. H. v. Wartenberg. *Z. anorg. allgem. Chem.* **242**, 406–12(1939).—By direct synthesis in a calorimeter the heat of reaction for the reaction $Ag + F_2 = AgF_2$ was found to be 84.5 ± 1.2 kg.-cal. The m. p. of AgF_2 is about 690° and its dissocn. pressure at 700° is less than 0.1 atm. H. A. Frediani

Phase-shift calculations for proton-proton scattering at high energies. H. M. Thaxton and L. E. Hoisington. *Phys. Rev.* **56**, 1194–8(1939).—The theoretical *s* wave shift for the square well and the Gauss error well, which

is fitted to expt. from 0.7 to 2.6 m. e. v., is calcd. up to energies of 10 m. e. v. Coulomb functions needed for this purpose are tabulated and the phase shift, as well as the ratio of theoretical scattering to that expected according to Mott's formula, is represented graphically as a function of the energy. Both the Gauss error well and the square well give similar extrapolations of the exptl. phase shifts to high energies. G. M. Petty 1

Critical conditions in neutron multiplication. R. Peierls. *Proc. Cambridge Phil. Soc.* **35**, 610–15(1939).—Theoretical. E. O. Wiig 2

The lengths of the links of unsaturated hydrocarbon molecules. C. A. Coulson. *J. Chem. Phys.* **7**, 1069–71 (1939); cf. *C. A.* **33**, 3690[6], 9279[1].—The lengths of the links in the series ethylene, butadiene, hexatriene, octatetraene and in C_6H_6, naphthalene and Ph_2 are calcd. on the assumption that there is a simple interaction energy between all contiguous C-C bonds. The lengths agree well with those calcd. from quantum-mech. ideas of resonance. G. M. Petty 3

Partial and total emissive power of various substances. III. Generalized Wien's law. A. Carrelli. *Atti accad. Lincei, Classe sci. fis. mat. nat.* **29**, 435–41(1939); cf. *C. A.* **34**, 21[5].—A formula is derived from Planck's law of emission from a black body, on the assumption that the emissivity is independent of temp The emissive power of Pt is 0.248 and graphite 0.212, compared with a value of 0.294 for a black body. A. W. Contieri 4

The effect of ionization and dissociation on the specific heat. F. Moglich, K. H. Riewe and R. Rompe. *Ann. Physik* **35**, 735–60(1939).—The sp. heat of gases undergoing dissocn. or ionization is calcd. by Planck's summation state method, translational, interval, and dissocn. or ionization energies are taken into account. At low pressures in the case of hydrogen the max. sp. heat occurs at 0.57 dissocn. or ionization; this max. is several hundred times the classical translational value. The calcn. is also applied to Hg for the first 4 ionization steps and briefly to semiconductors. E. O. Wiig 5

Ionization in the positive column. B. N. Klyarfel'd. *Compt. rend. acad. sci. U. R. S. S.* **24**, 251–3(1939) (in English).—Theoretical. The results of a previous paper (*C. A.* **33**, 4865[9]) are modified by introducing a new method for evaluating the efficiency of noncumulative ionization processes in low-pressure discharges. The calcd. values now agree to within 10–15% with the exptl. results of Nottingham (*C. A.* **33**, 2795[7]). T. H. Dunkelberger 6

The atom-physical interpretation of Lichtenberg figures and their application to the study of gas-discharge phenomena. F. H. Merrill and A. Von Hippel. *J. Applied Phys.* **10**, 873–87(1939). Discharges in N_2 between 5 mm. and 30 atm. pressure progress in 3 stages—the primary figure, spark development and the discharge of neg. surface charges. Admixts. of CCl_4 or Freon up to 6 atm. show the influence of electroneg. components on the development of the phenomena and reveal the reason why these gases are effective in suppressing corona discharges. Deviations from Pascen's law can be interpreted in terms of the photographic evidence obtained. S. L. G. 7

New data on secondary emission. N. S. Khlebnikov. *Uspekhi Fiz. Nauk* **21**, 301–37(1939).—Data are given on the secondary emission as a function of the voltage from clean, oxidized or partially or thoroughly degassed Cs, Cs-Ag, Be (in H_2 atm.), W, Ni, Ag, Sb-Cs and KCl emitters at various temps. F. H. Rathmann 8

Ionization by collisions of the second kind in a gas discharge. A. A. Zaĭtsev and E. M. Reĭkhrudel. *Uspekhi Fiz. Nauk* **20**, 447–68(1938).—From exptl. data on He, Ne and A, Z. and R. conclude that collisions of the second kind play an important and at times a predominant role in detg. the spectral and elec. characteristics of a discharge. F. H. Rathmann 9

The Townsend ionization coefficients for nickel and aluminum cathodes in an atmosphere of hydrogen. Donald H. Hale. *Phys. Rev.* **56**, 1199–1202(1939); cf. *C. A.* **33**, 6138[8].—Values of the α- and γ-coeffs. are compared with those for a Pt surface in H. Values of α/p (in H) plotted against X/p decrease for X/p from 900 to 1400. Values of γ plotted against X/p show a photoemission peak at $X/p = 131$, and a gradual rise at higher values of X/p. Sparking potential curves are calcd. from the γ-values and are compared with experimentally detd. curves. G. M. Petty 10

The absorption of high-energy electrons. IV. M. M. Slawsky and H. R. Crane. *Phys. Rev.* **56**, 1203–10 (1939); cf. *C. A.* **31**, 6546[9], 8351[2]; **32**, 4422[2].—The scattering of electrons in Pb and Al was studied, chiefly under conditions used previously for the study of energy loss. The primary object was to det. the extent to which existing energy-loss data (up to 13.5 m. e. v.) are affected by multiple scattering. Measurements made in Pb with electrons below 9 m. e. v. are so much affected by multiple scattering in the absorbing material that they are useless as a direct check on the theory for energy loss. From 9 to 13.5 m. e. v. the scattering losses are about 40% above theoretical; here a comparison with theoretical values is possible. Measurements were made on the multiple scattering of 0.9-m. e. v. electrons in thin sheets of Al. The most probable angle of scattering and the av. angle of scattering were in good agreement with theoretical predictions. G. M. Petty 11

A portable apparatus for recording bursts of cosmic-ray ionization. C. G. Montgomery and D. D. Montgomery. *Rev. Sci. Instruments* **10**, 350–2(1939). E. H. 12

A discussion of theoretical formulas and curves relating to γ-rays. T. Kahan. *J. phys. radium* **10**, 430–4(1939). —Math. and theoretical. Various expressions concerning the photoelec. effect, Compton effect, and the formation of positron-negatron pairs are discussed and their limits of validity are defined. The behavior of the 3 effects as a function of the at. no. and of the energy of the incident photon is detd. Curves are presented showing the relative importance of the 3 effects in the electron bombardment of Al, Cu and Pb specifically, as well as for the general case. T. H. Dunkelberger 13

Intensity of mesotrons in the upper atmosphere. E. G. Dymond. *Nature* **144**, 782(1939); cf. Carmichael and D., *Proc. Roy. Soc.* (London) **A171**, 321(1939).—The intensity of vertically directed mesotrons rises to a max. of 9 times the ground value at a pressure of 80 mm. Hg (16 km. height). The theoretical work of Euler and Heisenberg (*C. A.* **33**, 4634) is brought into agreement with these data by assuming that the min. energy of production of mesotrons is 8×10^8 e. v. G. M. Petty 14

Lifetime of the mesotron. Ira M. Freeman. *Nature* **144**, 667(1939); cf. *C. A.* **32**, 4869[4].—On the assumption that a heavy electron is a quasi-stable state of an ordinary electron, the life of the mesotron is calcd. to be 2.48×10^{-6} sec. G. M. Petty 15

The production of yukons (mesotrons). Guiseppe Cocconi. *Nuovo cimento* **16**, 78–85(1939).—The curve of Bowen, Millikan and Neber (*C. A.* **32**, 5695[4]) is modified to give a spectrum for electrons forming primary cosmic rays which is in better agreement with measurements at high altitude. Assuming that yukons are the least penetrating part of cosmic rays, C. calcs. from the latitude effect the probability of production of yukons by primary electrons. J. B. Austin 16

Absorption of slow mesotrons in matter. Hideki Yukawa and Taisuke Okayama. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 385–9(1939).—Math. E. O. Wiig 17

A thallous sulfide photovoltaic cell. Foster C. Nix and Arnold W. Treptow. *J. Optical Soc. Am.* **29**, 457–62 (1939).—A photo-e. m. f. cell effect is observed in Tl_2S produced by partial sulfurization of a Tl disk or of an evapd. Tl layer. The photosensitivity is observed to be as high as 6000×10^{-6} amp./lumen. Both open-circuit voltage and short-circuit current are observed in some cells to be directly proportional to the incident-light intensity at all temps. In other cells, especially those displaying high photoresponse, both tend to sat. at high light intensities. The spectral photosensitivity curve possesses a max. at 9800 A. ± 200 A. with long-wave and short-wave thresholds at 15,000 and 6500 A., resp. The short-circuit cur- 18

rent increases with decreasing temp. down to about −45° and then decreases continuously down to −180°. The photoelec. output when measured as a function of frequency of interruption of the incident light displays a recession of 75% at 20,000 cycles. M. Farnsworth 1

Photovoltaic cells: The spectral sensitivities of copper, silver and gold electrodes in solutions of electrolytes. Paul E. Clark and A. B. Garrett. *J. Am. Chem. Soc.* **61**, 1805–10(1939).—The sensitivity is detd. over the range 3650 to 6908 A. The photovoltaic threshold for different conditions is detd. The sensitivity of coated and some metal electrodes at 5461 A. is ascribed to the coating. A vacuum-tube circuit for measuring photopotentials is described. J. B. Austin 2

The optical translucence of selenium as connected with its photoelectric conductivity. G. Mönch. *Physik. Z.* **40**, 487–8(1939).—The position of the diffuse absorption edge is detd. spectrographically in the range −200° to +50°. It is concluded that the photoelec. properties of gray Se are due to the presence of traces of red Se. J. B. Austin 3

A photoelectric meter with a photocathode of CuI, filled with ethyl alcohol vapor. D. Ilkovič. *J. chim. phys.* **36**, 140–6(1939).—The elec. and optical properties of the meter are described in detail. The app. has an abs. sensitivity near 2350 A. of 2–6 photons/sec./sq. cm. G. M. Petty 4

Electron interference for light molecules by the sector method. P. Debye. *Physik. Z.* **40**, 404–6(1939).—An extension of *C. A.* **33**, 3678², giving more details and recent improvements. Illustrations are given for CCl_4, C_2H_2 and NH_3. J. B. Austin 5

The resonance capture of slow neutrons and emission of γ-rays. Itaru Nonaka. *Proc. Phys.-Math. Soc. Japan* **21**, 594–608; *Nature* **144**, 831–2(1939).—Neutron resonance energies were detd. for some elements which are not made radioactive by neutron capture. The intensity of γ-rays emitted from Fe, Cd, Hg and Bi by slow-neutron capture was measured as a function of the thickness (0–12 cm.) of a paraffin layer interposed between a D + D neutron source and a detector. From an analysis of the γ-ray intensity curves and from measurements of energy by B absorption, a resonance of 10 e. v. was found in Hg, a resonance group of 5–7 e. v. in Bi, and several resonances from a few to several tens of e. v. in Cd. No distinct resonance groups were found in Fe. The mean energy of the Cd groups plus the residual energy of the first group (Er^3 = 0.17 e. v.) not absorbed by 0.43 g./sq. cm. Cd is about 2 e. v. The app. and technique are described. G. M. Petty 6

A simple apparatus for producing neutrons. Carl-friedrich Weiss and Hans Westmeyer. *Physik. Z.* **40**, 461–6(1939).—The app. uses the reaction ${}_1D^2 + {}_1D^2 \rightarrow {}_2He^3 + {}_0n^1$. The source of ions is a low-tension arc with a hot cathode. The app. costs 2000 marks and gives a max. yield equiv. to 1 g. (Rn + Be). J. B. Austin 7

Energy of high-velocity neutrons by the photographic method. C. F. Powell and G. E. F. Fertel. *Nature* **144**, 115–16(1939).—The B + D proton spectrum and the B + D and Be + D neutron spectra were studied by the counter method, the expansion-chamber method, and a direct photographic method in which the protons or neutrons passed tangentially into an Ilford "half-tone" plate. The resolving powers of the methods for protons (25–100-cm. range in air) are comparable. With neutrons, the photographic method (*a*) is equiv. to a continuously sensitive, high-pressure expansion chamber, (*b*) involves a min. of material (and equipment) and does not give rise to disturbing scattered neutrons, and (*c*) uses a small plate placed very near the neutron source, with a corresponding gain in intensity. G. M. Petty 8

Angular distribution of the fast neutrons scattered by atoms. II. Tetuo Wakatuki and Seisi Kikuti. *Proc. Phys.-Math. Soc. Japan* **21**, 656–60(1939).—Continuation of former research (*C. A.* **33**, 6141⁸, 8491⁶) and extending the scattering angles up to 152°. In the small-angle region the agreement with the old value was found quite satisfactory, and the authors believe it to be predominantly elastic scattering. For angles larger than 55° σ was found to be nearly const. ($\sigma(\theta)$ is, the differential scattering cross section), while for smaller angles it increased regularly with decreasing angles. Fast Li + D neutrons were found to act quite similarly to D + D neutrons. Frank Gonet 9

The scattering of α-particles by nitrogen. Gordon Brubaker. *Phys. Rev.* **56**, 1181–3(1939).—α-Particles are scattered by N into 4 angular ranges of mean angles 53°, 66°, 88° and 104°. Anomalies in the scattering are observed for energies as low as 3.5 m. e. v. Curves showing the ratio of observed to Coulomb scattering as a function of energy show several maxima and minima. Forms of the curves vary greatly with the scattering angle. G. M. Petty 10

Transformations of atomic nuclei produced by collisions with material particles. N. Bohr and F. Kul'kar. *Uspekhi Fiz. Nauk* **20**, 319–40(1938).—Theoretical review. Distribution of energy levels, emission of radiant energy by nuclei, emission of neutrons and charged particles, and effects of collisions with slow neutrons and with charged particles are discussed. F. H. Rathmann 11

Artificial disintegration of heavy nuclei. E. V. Shpol-skiĭ. *Uspekhi Fiz. Nauk* **21**, 253–60(1939).—A review, chiefly of the work of Hahn and his coworkers, on the explosive disintegration of uranium under the action of neutron bombardment. F. H. Rathmann 12

The cyclotron of the Biochemical Research Foundation. A. J. Allen, M. B. Sampson and R. G. Franklin. *J. Franklin Inst.* **228**, 543–61(1939).—This cyclotron, with its improved ion source using tungsten ribbon filaments, delivers a current of 30 microamperes of deuterons at 11 m. e. v. on an external target. Various improved features of the app., e. g., design of the magnetic circuit, and construction of the vacuum tank and deflector, of dee supports with a convenient arrangement for adjustment of the dees, and of a high-frequency system for supplying voltage to the dees, are given in detail (with drawings and photographs) together with the results of a survey of the magnetic field with and without "shimming." E. B. S. 13

The preparation of polonium-beryllium neutron sources. Ch. Haenny and M. Haïssinsky. *J. chim. phys.* **36**, 218–20(1939).—A neutron source prepd. by chem. pptn. of Po in a Be tube and subsequent filling with Be chips gave a neutron yield twice that of a similar amt. of Po on Ag strips similarly surrounded by Be. H. C. T. 14

Coincidence experiments on the nuclear transformation of boron when bombarded by protons. Kurt Fink. *Ann. Physik* **34**, 717–39(1939).—A study of the reaction $B^{11} + H = He^4 + Be^8$ leads to the conclusion that Be^8 is not stable but breaks up immediately into 2 α-particles. The α-particles have a range of 44 mm. The no. of observed coincidences is considerably smaller than one would expect on the basis of spacially symmetrical decompn. of the Be^8 atoms. P. H. Emmett 15

Experiments on the transmutation of fluorine by deuterons. J. C. Bower and W. E. Burcham. *Proc. Roy. Soc.* (London) **A173**, 379–91(1939).—The emission of protons from F bombarded by deuterons of 0.8-m. e. v. energy was studied in an expansion chamber. Five groups of protons of ranges of 13.0, 18.8, 21.0, 24.2 and 31.0 cm. were found, and from their energy values the authors conclude that in the radioactive F^{20} nucleus there exist excitation levels at 0.7, 1.0, 1.35 and 1.9 m. e. v. above the ground state. A mass of 20.0063 is deduced from the energy of the 31-cm. group, which gives an energy release of 7.0 m. e. v. in the β-decay of F^{20} to Ne^{20}. The disagreement between this value and the observed β-ray end-point of 5.2 m. e. v. is partially reconciled by the observation that a γ-ray emission of 2.2 m. e. v. accompanies the β-emission. The authors discuss the origin of this γ-radiation in terms of the level system of Ne^{20}. The exptl. results were found not to support the original theory of Bethe, *et al.* (*C. A.* **34**, 3678⁷) on the complexity of the β-ray spectrum of F^{20}. A new transmutation of the C^{13}-isotope by deuterons is also reported. F. G. 16

Concentration of radiophosphorus ${}_{15}P^{32}$ by means of an electric field. J. Govaerts. *J. chim. phys.* **36**, 130–9 (1939).—Radio-P is deposited on Cu electrodes in an elec. 17

field of 165 v./cm. When CS_2 is irradiated with Ra + Be neutrons, all the radio-P is deposited on the electrodes. When CCl_4 is irradiated, the radio-P is not completely pptd. on the electrodes. When Al electrodes are used, only part of the radio-P is deposited from irradiated CS_2. The black deposit which forms on Cu electrodes arises from the decompn. of CS_2 by the penetrating rays from Ra. The radio-P is readily recovered from the electrodes on treating them with HNO_3. G. M. Petty 1

Radioactive arsenic isotopes. R. Sagane, S. Kozima, G. Miyamoto and M. Ikawa. *Proc. Phys.-Math. Soc. Japan* **21**, 660–71(1939).—Decay periods of six radioactive arsenic isotopes were investigated by bombarding Br, Se, As and Ge with either deuterons or fast and slow neutrons from the Berkeley (5.5–7.6 m. e. v.) and the Tokyo (3 m. e. v.) cyclotrons. The following results were obtained: (1) As^{78}: When Br^{81} was bombarded with neutrons the As^{78} obtained [$Br^{81}(n,\alpha)As^{78}$] was found to have an activity (e^-) of 65 min. and an upper limit of 1.4 m. e. v. This isotope was also believed to be produced by fast neutron bombardment of Se^{78} [Se^{78} (n,p) As^{78}]. (2) As^{77}: When Ge^{76} was bombarded with deuterons the As^{77} obtained [$Ge^{76}(d,n)$ As^{77}] gave an activity (e^-) of 90 ± 10 days, and an upper limit of about 0.12 m. e. v. The (e^-) emitted was very soft. (3) As^{76}: The As isotope produced by the following reactions, [$Br^{79}(n,\alpha)$ As^{76}; $Se^{76}(n,p)$ As^{76}; $As^{75}(n,\gamma)As^{76}$; and $As^{75}(d,p)As^{76}$] gave a strong activity (e^-) of 26 hrs. The β-rays were studied in a cloud chamber and 2 components were found, the upper limits of which were 1.31 m. e. v. and 2.75 m. e. v. At least two γ-ray lines were observed (0.5 and 1.5 m. e. v. and a half-value thickness of 3 and 10 mm. Pb, resp.). The prepn. of As^{76} was chemically checked. (4) As^{74} produced by bombarding Ge with deuterons [$Ge^{73}(d,n)$-As^{74} and $As^{75}(n,2n)As^{74}$] gave a strong 16-day period. Cloud-chamber studies showed the emission of e^- and e^+, the upper limits of which were estd. to be 0.9 and 1.3 m. e. v., resp. The expt. was repeated with Li + D neutrons and a 16 ± 1 day period was also obtained and the upper limits of the β-ray spectrum was found to coincide with the Ge + D results. (5) As^{73} and As^{71} (?) were believed to be produced when Ge was bombarded with deuterons [$Ge^{72}(d,n)As^{73}$ and $Ge^{70}(d,n)As^{71}$] as 2 positron activities of 88 min. and 50 hrs. were found. This result was not obtained when Ge was bombarded with neutrons. The authors suppose that the 88-min. period is due to As^{73} and the 50-hr. period to As^{71}. No chem. tests have been carried out as yet, for the Tokyo cyclotron is still too weak to produce sufficient exptl. material. The chem. method of sepn. is given. Frank Gonet 2

A method for preparing neutron sources of long-time action. A. Polesitskiĭ and A. Ratner. *Compt. rend. acad. sci. U. R. S. S.* **24**, 250(1939) (in English).—A soln. of a Ra or Rd-Th salt is mixed with a neutral soln. of 0.8 g. $BeCl_2$ in 200 ml. H_2O and also with approx. 2 g. of metallic Be. A soln. of NH_4OH (contg. some Na_2SO_4 in the case of the Ra salt) is added with vigorous stirring. After 15 min. the ppt. is filtered off, dried at 110° and then ignited at 300°. The resulting powder of Be + BeO is placed in a gilded metallic tube and carefully soldered shut to avoid any diffusion of Rn or thoron. Compared with the usual Rn + Be source, the Ra prepn. has an intensity of 0.8; that of the Rd-Th prepn. is 1.2. T. H. D. 3

Experiments on the transmutation of sodium by deuterons. E. B. M. Murrell and C. L. Smith. *Proc. Roy. Soc.* (London) **A173**, 410–17(1939).—The transmutation of Na bombarded by deuterons of 0.85-m. e. v. energy was investigated. The two groups of α-particles emitted, with ranges 5.0 ± 0.1 and 3.4 ± 0.1 cm. are attributed to the process: $Na^{23} + H^2 \rightarrow Ne^{21} + He^4$; where the former gave a value of 22.9961 ± 0.0003 for the mass of Na^{23} and the latter indicates an excitation level of 1.6 m. e. v. above the ground state in the Ne^{21} nucleus. Four groups of protons were also found with ranges of 7.5, 24.0, 33.4 and 37.8 cm. The energy of the longest group gave a value of 23.9976 ± 0.0003 for the mass of the Na^{24} atom, and the other groups gave excitation levels at 0.38, 1.26 and 3.38 m. e. v. above the ground state in the Na^{24} nucleus. Using these values, the authors obtained a value of 23.9913 ± 0.0003 for the mass of Mg^{24}. Frank Gonet 4

The peculiar nuclear properties of samarium and its structural isomerism. W. Wefelmeier. *Ann. Physik* **36**, 373–80(1939).—On the assumption that changes between isobars have taken place at lower temps. than those required for conversions with a change in mass, the anomalous distribution of the abundance of Sm isotopes is in part explained. The remainder of the anomaly is clarified by considerations of isomerism. Henry C. Thomas 5

The application of artificial radioelements to the clearing up of a question of complex chemistry. A. A. Grinberg and F. M. Filinov. *Compt. rend. acad. sci. U. R. S. S.* **23**, 912–14(1939) (in German); cf. Roginskiĭ and Gopshtein, *C. A.* **29**, 6834[9].—By neutron irradiation of $C_2H_4Br_2$ and shaking of the product with a dil. KBr soln. radioactive Br was obtained and used to det. the exchangeability of the 4 Br atoms in K_2PtBr_4 and the 6 Br atoms in K_2PtBr_6 for Br of KBr. All the Br atoms in each were found exchangeable for Br of KBr. This probably means that the three coördinate positions in the octahedron of $PtBr_6$ are equiv. Oden E. Sheppard 6

A completely portable radioactivity meter requiring no high-voltage battery. Herman F. Kaiser. *Rev. Sci. Instruments* **10**, 218–19(1939).—A simple vacuum-tube oscillator circuit is used for generating the high potential necessary for operating a Geiger-Müller tube. The app. has a simplified counting rate meter, compactness, flexibility and complete portability. G. M. P. 7

Radium exposure meter. Leon F. Curtiss. *J. Research Natl. Bur. Standards* **23**, 479–84(1939) (Research Paper No. 1246).—The meter is a modification of a portable Geiger-Müller counter unit with a sensitivity range that is suitable for indicating when the tolerance dosage for γ-ray exposure has been exceeded. A wiring diagram and directions for building the meter are given. M. Farnsworth 8

Some peculiarities of the atoms from the nuclear fission of uranium and thorium. Otto Hahn. *Ann. Physik* **36**, 368–72(1939).—A discussion. Henry C. Thomas 9

Delayed neutron emission accompanying uranium fission. K. J. Bostrøm, J. Koch and T. Lauritsen. *Nature* **144**, 830–1(1939).—It has been shown that the fission of U is followed by β-ray periods of 45, 10, 3–4 and 0.3–0.9 sec. Neutron emissions connected with the 2 longer periods have been reported; neutron periods of 3 sec. and 0.1–0.3 sec. were found. The total cross section for periods down to 0.1 sec. is less than 2×10^{-25} sq. cm. The theoretical analysis of Bohr and Wheeler (*C. A.* **33**, 9115[5]) gives a simple explanation of these results. G. M. Petty 10

Fission of uranium under deuteron bombardment. D. H. T. Gant. *Nature* **144**, 707(1939).—When U is bombarded with high-energy deuterons, recoil radioactive nuclei are projected about 2 cm., owing to a fission of U. The threshold energy is about 8 m. e. v.; the cross section increases rapidly from 8 to 9 m. e. v. G. M. Petty 11

Splitting of the uranium and thorium nuclei into two complex nuclei. I. N. Golovin. *Uspekhi Khim.* **8**, 529–36(1939). **The splitting of the uranium and thorium nuclei. Experimental evidence for the explosive disintegration of uranium and thorium nuclei under neutron bombardment.** Frederick Joliot. *Ibid.* 537–9; cf. *C. A.* **33**, 4509[1]. **Radioelements formed in uranium and thorium irradiated by neutrons.** I. Joliot Curie and P. Savich. *Ibid.* 540–2; cf. *C. A.* **33**, 2408[8]. **Physical basis for the division of heavy nuclei under neutron bombardment.** S. Frish. *Ibid.* 542–4. **Disintegration of heavy nuclei.** Niels Bohr. *Ibid.* 544–5; cf. *C. A.* **33**, 3685[2]. F. H. Rathmann 12

Element 87, actinium K, derived from actinium. M. Perey. *J. phys. radium* **10**, 435–8(1939); cf. *C. A.* **33**, 2030[8].—Chem. sepn. of the products resulting from the disintegration of Act showed the appearance of a radioactive alkali metal with a half-life period of 21 min. This element is produced by α-disintegration of Act; about 1% of Act disintegrates in this way instead of by loss of a β-particle. Act K is a β-emitter. T. H. Dunkelberger 13

The β-radiations of uranium X_1 and uranium X_2. J. S. Marshall. *Proc. Roy. Soc.* (London) **A173**, 391–410 (1939).—The distribution with momentum of the β-rays of U X was investigated by a cloud chamber for values below $H\rho$ 2000 (280 e. kv.) and a magnetic spectrometer (for higher values). The β-rays of U X_1 were found to extend at least to $H\rho$ 1950 (265 e. kv.). The spectrometer values give a β-ray line at $H\rho$ 3600 (686 e. kv.), intensity 0.0036 ± 0.0004 per disintegration, indicating the presence of an 802-e. kv. γ-ray. The continuous distribution for the U X_2 β-rays (above $H\rho$ 3000) is interpreted as formed of 2 partial Fermi-type spectra, one contg. 95% of the intensity and extending to $H\rho$ 9300 (2.32 m. e. v.) and the other with about 5% of the total intensity and extending to $H\rho$ 6550 (1.52 m. e. v.). An internal conversion coeff. for the γ-ray of about 0.07 is found from the γ-ray intensity and the strength of the β-ray line. The energy of the γ-ray agrees with the energy values of the γ-rays of U Z (Feather and Bretscher, *C. A.* **32**, 6146[9]), and constitutes added evidence for the isomerism of the nuclei U X_2 and U Z. Frank Gonet

Concentration of the heavy oxygen isotope by redistillation of water, and the isotopic analysis of water. A. I. Brodskiĭ and O. K. Skarre. *J. Phys. Chem.* (U. S. S. R.) **13**, 451–63(1939).—See *C. A.* **33**, 7662[8]. F. H. R.

The spin of carbon thirteen. C. H. Townes and W. R. Smythe. *Phys. Rev.* **56**, 1210–13(1939).—C^{13} of methane was concd. in a Hertz diffusion system; enough 35% C^{13} was obtained for a measurement of the nuclear spin. The C^{13} nucleus obeys the Fermi-Dirac statistics; it has a spin of 3/2. This is the value predicted by the α-particle model; the Hartree nuclear model predicted 1/2. G. M. Petty

The photography of interatomic distance vectors and of crystal patterns. M. J. Buerger. *Proc. Natl. Acad. Sci.* **25**, 383–8(1939).—Extension of the Bragg method of obtaining the 2-dimensional Fourier summation optically to cases for crystals having a projected center of symmetry, for detg. interat. distance vectors and for application of purely photographic processes is outlined. Use is made of an appropriate set of polaroid strips. Preliminary operations for summation of the equations involved using photographic processes are described which produce a diffraction picture as a direct photograph of the crystal itself. Plane gratings for the Patterson-Harker syntheses are prepd. photographically. Various procedures for accomplishing the technique are clearly described. Raymond H. Lambert

Construction of a 10-kw. rotating-anode Röntgen tube and investigation of the structure of salt solutions. Jürgen Beck. *Physik. Z.* **40**, 474–83(1939).—The construction of the tube is described. The scattering of Cu *K* radiation was detd. in solns. of LiCl, LiBr and RbBr at concns. up to 13.3, 12.3 and 5.16 mol. per l. resp. At high concn. the scattering of H_2O is repressed. The data are incompatible with the assumption of a random distribution of ions in the soln. They indicate that H_2O has a distorted lattice structure in which the ions are located. At high concn. the whole structure becomes similar to that of a solid salt contg. H_2O. J. B. Austin

Note on the integration of the equation of the formation of absorption lines. H. R. Hulme. *Monthly Notices Roy. Astron. Soc.* **99**, 730–2(1939).—The equation of the formation of absorption lines is integrated for the case in which $(1 + \eta)^{-1} = \alpha + \beta\tau + \gamma\tau^2$ in which τ is the optical depth, η is the ratio of the line absorption to the continuous absorption, and α, β, γ are consts. C. C. Kiess

Problems of solar eclipses. V. G. Fesenkov. *Astron. J. Soviet Union* **16**, No. 2, 1–16(1939).—F. discusses the spectrophotometric data obtainable, in particular as regards the amts. of H, He, Ca and Na present. F. H. Rathmann

Revised spectrophotometric temperature of nova Herculis 1934. B. Voroutsov-Vel'yaminov. *Astron. J. Soviet Union* **16**, No. 2, 17–29(1939).—The max. temp. was 12,000°, the effective (Pannekoek) temp. 7300 ± 500°. Ultraviolet radiation in excess of that for black-body radiation is ascribed partly to continuous H emission and partly to extended atms. Bands due to CN appear at the time of max. brightness. F. H. Rathmann

Methods of meteoric astronomy in the study of the stratosphere. I. S. Astapovich. *Astron. J. Soviet Union* **16**, No. 1, 28–41(1939).—A list of 50 spectral lines of Fe, Ni, Ca, Mg, Mn, Al, Cr, Na and Si observed in meteor spectra is given. No conclusions as to the compn. of the upper atm. can be drawn from meteor spectra. F. H. Rathmann

The ultraviolet spectra of A and B stars. Otto Struve. *Astrophys. J.* **90**, 699–726(1939).—Approx. 350 absorption lines have been measured in the ultraviolet region (3227 to 3957 A.) of the spectra of some stars of class *A*. These have been identified with known lines of H, Fe I, Fe II, Cr II, V II, Sc II, Ti II, Y II, etc. Approx. 200 lines measured in the same region of some class *O* and *B* stars have been identified with known lines of He I, Ne II, O II, O III, N II, N III, S III, Ca III, Fe III, etc. C. C. Kiess

The ultraviolet spectra of 17 Leporis and P Cygni. O. Struve and F. E. Roach. *Astrophys. J.* **90**, 727–53(1939).—In 17 Leporis the lines of Ti II, Sc II and Mn II are strong; those of Si II abnormally weak. In P Cygni the Balmer series of H is measured up to $n = 23$; 6 series of He I are present, the $2^3P - n^3D$ series being measured up to $n = 21$, and the $2^1P - n^1D$ series up to $n = 14$. Other P Cygni lines are identified with Fe III, Si III, Fe II, N II, Ti II, etc. C. C. Kiess

The spectrum of the night sky and of the zodiacal light observed at the astronomical station at Windhuk, Southwest Africa. C. Hoffmeister. *Z. Astrophys.* **19**, 116–31 (1939).—Wave lengths of 19 emission lines that appear in the light of the night sky are communicated. The spectra of the zodiacal light and of the Gegenschein appear to be that of reflected sunlight on which is superimposed the weakened night-sky spectrum. The bright line at 3914 A. appears strengthened in the zodiacal light. C. C. Kiess

The transparency of the atmosphere in the ultraviolet and a possible means of extending the solar spectrum in the region 2200–2000 A. K. R. Ramanathan and L. A. Ramdas. *Proc. Indian Acad. Sci., Symposium on Molecular Structure*, Aug. **1934**, 103–12; also in *Proc. Indian Acad. Sci.*, **A 1**, 308–14(1934).—Between the short-wave limit of the absorption band of atm. O_3 at 2200 A. and the beginning of the O_2 band at 2000 A. there is a window through which sunlight should be transmitted. Since none is received at the earth's surface there must be some absorbing agent in the atm. near its lowest level; probably another continuum of O_2 beyond the convergence limit at 2400 A. of the weak bands described by Herzberg (*C. A.* **26**, 5495). It is pointed out that if a spectrograph can be exposed at levels higher than 16 km. above the earth's surface in the tropics there is great likelihood of recording the sun's spectrum in the interval 2200–2000 A C. C. Kiess

Hyperfine structure of the spark spectrum of iodine. S. Tolansky. *Nature* **144**, 754–5(1939); cf. *C. A.* **33**, 4517[6].—Reply to Schmidt (*C. A.* **34**, 25[6]). The data of Murakawa (*C. A.* **33**, 6716[3]) agree with those of Tolansky G. M. Petty

Anomalous dispersion in lead vapors. K. I. Zhemchtsova. *J. Exptl. Theoret. Phys.* (U. S. S. R.) **9**, 566–9 (1939).—Using the method of Rozhdestvenskiĭ (cf. *C. A.* **7**, 446), Zh. found that in Pb vapors at 800–920°, the ratio f_1/f_2 for the lines 2170 and 2833 A. is 1.85 ± 0.06 or $(f6^2P_0 - 7S^3P_1)/(f6^3P_0 - 6d^3D_1) = 0.540$. Comparison with other data on Na and Tl vapors indicates that the ratio of the dispersion centers of the head lines of the sharp and the diffuse series increases with increasing at. wt. F. H. Rathmann

The Stark effect of the Balmer lines after passage of the atoms through a very strong electric field. Rudolf Ritschl. *Physik. Z.* **40**, 413–15(1939).—When H canal rays are passed through an elec. field so strong that the component displaced toward the red vanishes through ionization, then on decreasing the field only the component displaced to the violet is observed. If now, after passing through the

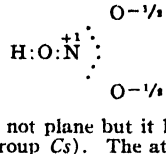
ionizing field, the atoms enter a second field, reversed with respect to the first, only the violet component appears but in increased intensity. J. B. Austin

Evidence of a nuclear chain reaction inside a uraniferous mass. H. von Halban, Jr., F. Joliot, L. Kowarski and F. Perrin. *J. phys. radium* **10**, 428–9(1939); cf. *C. A.* **33**, 6146⁷.—A Cu sphere 50 cm. in diam. has a source of photoneutrons (1 g. Ra + 160 g. Be) at the center. The neutron d. inside and around the sphere is measured with a Dy detector when the sphere is filled with water, with dry U_3O_8, and with U_3O_8 plus various proportions of water. A consideration of the no. of neutrons detected at various distances form the source, in the light of the av. life of *thermal* neutrons, leads to the conclusion that in the presence of U some of the neutrons are of secondary, tertiary or higher origin. This indicates the presence of a converging chain reaction in such nuclear processes. At least 8 nonprimary neutrons are produced by each primary process. T. H. Dunkelberger

Line absorption and total absorption of copper resonance lines, and determination of the radiation temperature in the gas column of the copper arc light. Herman Schnautz. *Spectrochim. Acta* **1**, 173–96(1939).—An arc light entirely free from self-reversal is described. The light is taken from the axis of the arc through an axial hole in the anode. By comparing the intensity in the center of the Cu line 3248 A. with that from the pos. crater of a C arc at temp. 3703°K. a mean value of 5473°K. is obtained for the temp. of the gas column of a Cu arc at atm. pressure. With the reversal-free light source, the course of line absorption with concn. is measured by detg. the intensity ratio of 2 lines of known statistical weight as a function of the intensity of 1 of the 2 lines. Thus the intensity ratio of the Cu resonance lines 3248 and 3274 A. is found to be 2 for very small concns., 1.4 for the greatest observed concns., and it sinks to 1.05 between these extremes. W. F. Meggers

The intensity of the resonance lines of an element in arc light in relation to its concentration. R. Mannkopff. *Spectrochim. Acta* **1**, 197–206(1939).—The nonlinear concn. sensitivity of spectral lines, especially at high concn. is caused not by self-reversal in the arc envelope but by self-absorption of the lines in the emitting layer, as is shown by a comparison of ordinary with stabilized reversalfree arcs (cf. preceding abstr.). With Cu this phenomenon can be explained by temp. ionization and migration of ions causing the arc interior to be depleted of atoms. This interpretation is supported by measurements of the intensity-concn. curve for the Be doublet 3130/3131 A. Since its degree of ionization is very small Be does not migrate out of the arc axis, and in this case the total intensity as a function of concn. is that expected for spectral lines whose width is detd. by Doppler effect and damping. W. F. Meggers

Investigation of a tube of molecular hydrogen. D. L. Astavin-Razumin. *Astron. J. Soviet Union* **16**, No. 2, 49–55(1939).—The intensity of radiation increases 20% for a 5% increase in voltage, is practically independent of the temp. from 0 to 20°, but increases by 60% at 60°, and increases as the gas disappears with aging. The use of a H tube for spectrophotometric comparison purposes is discussed. F. H. Rathmann



The molecular binding energy between atomic hydrogen and aluminum atoms in aluminum. H. Schüler, H. Gollnow and E. Fechner. *Ann. Physik* **36**, 328–34(1939).—From spectroscopic observations in a hollow cathode it is found that AlH mols. exist in metallic Al. The unusual intensity of AlH bands is due more to the evapn. of AlH from the metal than to its formation in the gas space. The binding energy between H and Al in Al detd. from the bands of the $^1\Pi - {}^1\Sigma$ transition at the lowest discharge pressure is 0.228 ± 0.004 e. v. Henry C. Thomas

Absorption spectra and chemical linkage. R. Samuel. *Proc. Indian Acad. Sci., Symposium on Molecular Spectra*, Aug. **1934**, 1–90.—A theory of linkage that explains the chem. behavior of all the elements is the one that regards electrovalency as the limiting case of covalency. According to this theory a covalent linkage is due to the bonding of electron pairs and the energy required to dissoc. the mol. decreases according to the no. of bonds that are weakened when the electrons are excited. If, however, an odd electron not participating in the linkage is excited the energy of dissocn. increases. Covalent linkage occurs in mols. in which the electrons from 2 different atoms join with counterbalanced spins to form the bonds. If an atom with more than half the max. no. of p electrons can receive from the combining atoms addnl. electrons beyond its nuclear charge until the max. is attained then the electrovalent linkage results. The expt̄l. facts that support these views are furnished by the absorption spectra of various mol. systems. The spectra of I_2, CO, halides of Ag, etc., are cited to illustrate systems in which dissocn. energy decreases with excitation; whereas the spectra of mols. with free valences, such as –NO or –Be O, illustrate the systems in which the dissocn. energy increases by excitation. Also from the absorption spectra of polyatomic mols. in the vapor state, of mols. in soln. and in the liquid and solid states, criteria are found to det. whether the linkages are covalent or electrovalent. C. C. Kiess

Application to the molecules concerned of the new analysis of molecular spectra. Simple relation between the frequencies of the same molecule in the gaseous and liquid states. Henri Deslandres. *Compt. rend.* **209**, 865–9(1939); cf. *C. A.* **34**, 2698.—The relation depends on such facts as that the infrared frequencies of gaseous and liquid SiH_4 are expressible as 5/17 of 175 and 5/17 of $174d_1$, resp., where d_1 is D.'s universal const. 1062.5 and 17 the no. of activated electrons. C. A. Silberrad

Inertial effects in the skeletal vibrations of tetramethylmethane and tetramethylsilicon. Samuel Silver. *J. Chem. Phys.* **7**, 1113(1939).—Wall and Eddy (*C. A.* **32**, 2402²) calcd. the vibrational frequencies of Me_4C and Me_4Si; their X-Y force const. was small. This was due to their failure to consider the motions of the H atoms relative to the C atom. G. M. Petty

The structure of nitric acid and of methyl nitrate. Jean Chédin. *J. phys. radium* **10**, 445–54(1939).—A comparison of expt̄l. Raman frequencies with those calcd. from various mol. models indicates that undissocd. HNO_3 possesses plane symmetry (C_{2v}) and probably has the electronic structure

The $MeNO_3$ mol. is not plane but it has a plane of symmetry (symmetry group Cs). The atoms O—NO_2 are in one plane and the C atom is in a plane perpendicular to this; the latter plane is the plane of symmetry of the mol. The angle C—O—N is approx. 116°. The NO_2 group has the same structure as in HNO_3. The nitrate ion belongs to symmetry group D_{3h} and has interat. forces $f = 4.4 \times 10^5$ and $f' = 2 \times 10^5$ dynes/cm.; f corresponds to a simple N·O bond and f' corresponds to a single-electron O.O⁻ bond. Also in *Mém. poudres* **29**, 111–33(1939). T. H. Dunkelberger

The absorption spectra of nitrates and nitrites in relation to their photodissociation. K. S. Krishnan and A. C. Guha. *Proc. Indian Acad. Sci., Symposium on Molecular Spectra*, Aug. **1934**, 91–102.—See *C. A.* **28**, 6370⁸. C. C. Kiess

Absorption spectrum of hypericin. N. Pace and G. Mackinney. *J. Am. Chem. Soc.* **61**, 3594–5(1939).—Absorption spectra for hypericin (I) are given for 90% aq. Me_2CO, 100% Me_2CO, 33% Me_2CO + 67% Et_2O, 25% Me_2CO + 75% Et_2O, 100% Et_2O, Et_2O and a trace of C_5H_5N, Et_2O and about 20% C_5H_5N and 100% C_5H_5N. Of particular interest is the coexistence of 2 distinct spectral types in homogeneous solns. of mixts. of Me_2CO and Et_2O. The data suggest the existence of a different mol. species of I in Et_2O, possibly an addn. compd., because the pigment is hydroxylated. This is capable of coexistence with a 2nd type (A_2) in anhyd. EtOH- or Me_2CO-Et_2O

mixts. In the presence of H_2O or C_5H_5N it disappears, leaving a spectrum of type A_1. C. J. West

The ultraviolet absorption spectra of some derivatives of 1,2-benzanthracene. R. Norman Jones. *J. Am. Chem. Soc.* **62**, 148–52(1940).—The ultraviolet absorption spectra of 1,2-benzanthracene and of 10 mono- and dimethyl derivs. were examd. and found to be closely similar in shape and intensity. Considerable variation is observed in the bathochromic shift of the position of the max. of the most intense band and this appears to show some correlation with the variation in the carcinogenic activity of the hydrocarbons. The spectrum of 1′,9-methylene-1,2-benzanthracene differs markedly from that of the other derivs. This variation may possibly be attributed to steric strain in the mol. A. B. Garrett

Light absorption by some derivatives of the bacteriochlorophylls. A. Stern and F. Pruckner. *Z. physik. Chem.* **A185**, 140–51(1939).—The visible and ultraviolet (680 to 230 mμ) absorption spectra are reported for the following derivs. of bacteriochlorophylls in dioxane soln. and compared with the spectra of the corresponding deriv. of chlorophyll: methylpheophorbide a, 2-acetylmethylpheophorbide a, bacteriomethylpheophorbide, 2-acetylchlorin e_6 trimethyl ester, bacteriochlorin e_6 trimethyl ester, chlorin e_6 trimethyl ester, bacteriopheopurpurin 7 trimethyl ester, bacteriochlorin e_6 trimethyl ester, pyrroporphyrin methyl ester and mesopyrrochlorin methyl ester. In the ultraviolet both classes of compds. show similar spectra, while in the visible large differences are to be detected. Victor R. Deitz

Absorption of polymolecular films in the infrared. G. B. B. M. Sutherland and W. T. Tutte. *Nature* **144**, 707 (1939).—Appreciable absorption at 3.3 μ due to CH groups was detected; a single reflection through a film of Me stearate 200 mols. thick was used. With a film 700 mols. thick, other bands between 6 μ and 10 μ were observed. The infrared absorption coeff. of a mol. seems to increase when it is in a surface film. G. M. Petty

Influence of temperature and coupling on the intensity of infrared vibrations. Frank Matossi. *Physik. Z.* **40**, 323–31(1939).—An application of dispersion theory for anharmonic linear coupled oscillations to *silicate* spectra. The intensity of vibrations depends on the degree of coupling and when there is an atom common to both oscillations, as in silicates, there is anomalous weakening of the octave. The 2 components of the octave have different intensities. The anharmonic binding const. as calcd. from the shift in the max. absorption coeff. with temp. agrees with observation. J. B. Austin

The Raman effect in organic chemistry. M. Burgel and M. Pio. *Uspekhi Khim.* **8**, 271–99(1939).—Review. F. H. Rathmann

Absorption of dipole liquids and electrolytes in the region of short electric waves. Karl Schmalc. *Ann. Physik* **35**, 671–89(1939).—Cond. measurements at high frequency for the dipole liquids water, glycol, acetone, $PhNO_2$ and PhCl show results in agreement with the Debye theory and the Malsch hypothesis of a relaxation time for the structure of the mols. (*C. A.* **33**, 3221[6]). Aq. solns. of cetylpyridinium chloride contg. 30% sugar show a selective absorption at wave lengths between 10 and 20 m. Hausser, *et al.* (*C. A.* **30**, 934[1]), Schmacks (*C. A.* **31**, 587[5]) and Linhart (*C. A.* **32**, 858[8]) have observed a similar effect. These results may be regarded as resonance effects or explained by the Malsch hypothesis. E. O. Wiig

The magnetic rotation of praseodymium, samarium and europium chlorides in aqueous solution at 25°. Charles M. Mason, Joseph W. Hickey and Wilfred K. Wilson. *J. Am. Chem. Soc.* **62**, 95–9(1940); cf. *C. A.* **30**, 7931[7].—The rotations were measured for the wave lengths λ = 4810.5, 5085.8, 5460.7, 5893, 6362.4, and 6438.47 A. except in those cases where absorption interfered. The *n*s of these aq. solns. were detd. at 25°. The Verdet consts. were calcd. The consts. for Sm and Eu solns. are pos. and those for Pr solns. are neg. when referred to water. The specific and mol. rotations were calcd. The values of the specific rotation for solns. of Pr are const. within limits of error but those Sm and Eu chlorides show a definite trend to decrease in the more concd. solns. An anomaly is observed in the comparison of the Verdet consts. with the known magnetic moments of these ions. The Bohr magneton nos. of Pr, Eu, Ce and Sm are 3.6, 3.4, 2.5 and 1.5, resp., but the magnetic optical rotatory powers of Eu are of the order of magnitude of those of Sm rather than those of Pr or Ce. A. B. Garrett

Spectrum of the torch discharge. Yosihiro Asami and Takeo Hori. *Nature* **144**, 981–2(1939).—The torch spectrum, which is obtained at a single electrode in an ultra high-frequency (10^7–10^8) undamped oscillation circuit, is essentially the same as that of the high-tension d.-c. arc. Bands due to O_2 (Runge), NO (γ) and OH in the flame, and N_2 and N_2^+ near the electrode, were observed. There is a continuous band from 6000 A. to the red end. The *Q* branch of the 3360 band of NH appears at higher c. d. G. M. Petty

Absorption spectra of heteropolar crystals and the crystal lattice energy. L. M. Shamovskiĭ. *Trans. All-Union Sci. Research Inst. Econ. Mineral.* (U. S. S. R.) No. **130**, 5–50(in English 51)(1938).—A critical review of the modern conception of the relation between optical and thermal properties of heteropolar crystals. Sixty-seven references. A. A. Podgorny

Cathodo-luminescence of luminescent magnesium silicates and some related magnesium minerals. Eiti Iwase. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 426–36(1939)(in English); cf. *C. A.* **32**, 8272[7], 6946[9].—The luminescence, as a result of cathode-ray bombardment, of synthetic Mg silicates to which were added, before calcination, small amts. of salts of Ag, Al, Au, Bi, Ca, Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, Sb, Sm, Sn, Th, Tl, U and Zn were observed visually and in part spectroscopically. In particular added Mn gives an intense red luminescence. A no. of native minerals were also examd. On passing from magnesite through dolomite to calcite there is a shift in the max. of the luminescent bands paralleling the change in chem. compn. The luminescence from a powd. carbonate mineral from Korea indicated the presence of Mg, which was borne out by chem. analysis. E. O. Wiig

Cleavage luminescence in mica. V. Ben Meen. *Univ. Toronto Studies, Geol. Ser.* No. **41**, 33–4(1938); *Mineralog. Abstracts* **7**, 404–5.—Pale-brown mica ($n_\beta = n_\gamma = 1.575$) from the magnesite mine at Kilmar (Quebec) shows a bluish white luminescence when split. The assocd. magnesite and dolomite are triboluminescent, resp. yellow and reddish orange, when struck. A pale-brown phlogopite from Buckingham (Quebec) also shows cleavage luminescence. C. A. Silberrad

Optical sensitization of silver halides. VII. Spectral sensitivity and absorption spectrum of sensitized layers of silver bromide. S. Natanson. *Acta Physicochim. U. R. S. S.* **11**, 67–74(1939)(in English); cf. *C. A.* **33**, 3707[9].—Graphical data for the effects of erythrosin, phloxine and rhodamine B are given in 3 figures. Conclusion: The shift of the sensitivity max. is due to the change of the absorption spectrum resulting from adsorption of the dye on the Ag halide. F. H. Rathmann

Photodissociation of ICN and BrCN molecules and the transfer of rotational energy on collision of the CN radical with foreign molecules. A. V. Yakovleva. *Acta Physicochim. U. R. S. S.* **9**, 665–80(1938)(in English); *J. Expll. Theoret. Phys.* (U. S. S. R.) **9**, 10–16(1939); cf. *C. A.* **33**, 8112[2].—The fluorescence of CN in ICN consists of bands at 3883 and 4216 A. and is accompanied by fluorescence of I_2 mols. In the region 3900–3800 A., the I_2 mol. shows 3 bands with max. at 3925, 3870 and 3800 A. The photodissocn. of ICN is accompanied by the formation of CN radicals in the electronic state $^2\Sigma^+$ and in the vibrational states $v' = 0, 1, 2$. The rotational energy of the CN radical for $v' = 0$ corresponds with 1140°K. With BrCN, CN fluorescence shows the same groups as with ICN. The magnitude of the effect of foreign gases in increasing the rotational temp. of the CN radical decreases in the order $A > N_2 = CO_2 > H_2$. B. C. P. A.

Some investigations on the photochemical methods for the measurement of ultraviolet radiation. T. Imai.

Hokuetsu Igk. Z. **52**, 952–66(1937); *Rev. Phys. Chem. Japan* **12**, 62(1938).—Among the various photochem. methods for the measurement of ultraviolet radiation, the oxalic acid method (Anderson and Robinson, cf. *C. A.* **19**, 2453) and the NH_4 molybdate method (Hanzawa, cf. *C. A.* **25**, 2643) were examd. The principal results of these expts. are: (1) The decompn. of oxalic acid is almost proportional to the amt. of the radiation, while the reaction of the NH_4 molybdate becomes slower with prolonged exposure. This may be due to the fact that the transmission index of radiation in the oxalic acid soln. does not change throughout the process, while in the NH_4 molybdate soln. it is decreased gradually with exposure. (2) For a const. exposed area the reaction value in a large quantity of soln. is greater, but the reaction value of unit vol. in a large quantity of soln. is smaller because of the transmission index. In the oxalic acid method the ratio of the equiv. value for unit vol. to the other is almost const. while in the NH_4 molybdate method it approaches 1 with prolonged exposure. (3) The reaction is influenced slightly by the reflection factor of the substance under the soln. In the oxalic acid method the influence is almost const., while in the NH_4 molybdate method it is reduced with the process of reaction. (4) Temp. has a slight influence on the reaction to almost the same extent in both methods. (5) Visible rays somewhat influence the reaction in both methods, to a greater extent in the oxalic acid method. E. H. 1 2 3 4

Studies on the reactions of the leucocyanides of the triphenylmethane dyes. I. The mechanism of the dark reaction following the photolysis of malachite green leucocyanide. Frank E. E. Germann and Charles LeRoy Gibson. *J. Am. Chem. Soc.* **62**, 110–12('1940).—Absorption studies of photolyzed and subsequently faded solns. of malachite green leucocyanide in alc. contg. some water have shown that the dark reaction does not regenerate the leucocyanide as an end product; nor is it leucocarbinol. The final product of the dark reaction is a colorless, light-sensitive substance with a peak in its absorption curve in the neighborhood of 3500 A. This end product is decompd. by dil. HCl to form a green soln. similar to that of malachite-green salts. A. B. Garrett 5

Photosensitized production of reducing sugars from starch. Lawrence J. Heidt. *J. Am. Chem. Soc.* **61**, 3588 9(1939); cf. *C. A.* **34**, 3255.—Substances which reduce the Shaffer-Hartmann-Somogyi reagent are produced when light is absorbed by aq. solns. contg. uranyl sulfate and starch. Quinine and fluorescein had little effect on starch. The quantum yield is smaller and falls more rapidly than for the photosensitized decompn. of sucrose at the same concn. of O bridges, if there is 1 bridge per sucrose mol. and 1 per glucose unit in starch. C. J. W. 6

Luminescent material. Humboldt W. Leverenz (to Radio Corp. of America). Can. 385,361, Nov. 28, 1939. A luminescent material consists of Mn-activated Be Zn salt of an ortho acid of an element in the second subgroup of the 4th group of the periodic system, e. g., Mn-activated Be Zn orthosilicate. Cf. *C. A.* **33**, 8130[1].

Luminescent tubes. Lloyd T. Jones. U. S. 2,177,891, Oct. 31. In producing a luminescent tube having a longitudinally striated discharge, an electrode of the tube is coated with an oily substance and the glass of the tube and its electrodes are heated to deprive them of occluded gases, the tube is evacuated, and is filled with an inert gas such as A and Hg at reduced pressure.

Luminous and radioactive compositions suitable for luminous paints. Raymond W. Gear. U. S. 2,178,961, Nov. 7. A method of making a luminous compn. involves adding concd. NH_3 soln. to a mixt. formed from S and KNO_3 for pptn. of a "nitrosulfate," adding to the latter, by pptn., activated sulfides obtained by pptn. with alc. from a mixt. formed from Th and Na nitrates and S, and thoroughly mixing the resulting composite mixt. with added luminous Ca sulfide.

Fluorescent-screen material. Russell H. Varian (to Farnsworth Television Inc.). Can. 384,697, Oct. 17, 1939. In a cathode-ray tube a fluorescent screen material consists of Zn tungstate contg. not more than 10^{-6} deactivating impurities.

Fluorescent-screen material. Russell H. Varian (to Farnsworth Television Inc.). Can. 384,698, Oct. 17, 1939. A Mn salt is heated with Zn borate, and the reaction product is mixed with pure ZnS at a temp. insufficient to cause combination of the Mn and ZnS.

Screen for cathode-ray tube. Philo T. Farnsworth and Harry S. Bamford (to Farnsworth Television Inc.). Can. 384,703, Oct. 17, 1939. A fabric of fine refractory W wire is knitted and mounted by its edges, and the diam. of the wire is decreased by etching in hot $NaNO_3$.

4—ELECTROCHEMISTRY

COLIN G. FINK

Review of the world development of the electrothermic and electrochemical industries. E. Houbart. *Bull. soc. belge electriciens* **55**, 418–50(1939).—A comparatively exhaustive review covering all important producing countries. As a whole, the world's electrochem. industry has more than tripled during the past 10 years. C. G F. 7

Process studies of the manufacture of calcium cyanamide. Karl Heilmann. *Z. Ver. deut. Ing., Beiheft Folge* **1939**, No. 4, 103–15.—Time-temp. relationships were detd. in a nitriding furnace of 0.8 m. diam. and 2.9 m. height. The charge was ground to approx. 8% on the 4900 mesh screen (corresponds to about 170 mesh Tyler Standard Screen Scale) and the compn. averaged CaC_2 79.5, $CaCN_2$ 20 and CaF_2 0.5%. Processing gave a vol. shrinkage of 10% of the initial vol. and a wt. increase of 22–23%. Time-temp. diagrams for longitudinal and cross sections are presented in 2 and 3 dimensions (isotherms). If the N_2 supply is sufficient, the reaction proceeds rapidly and uniformly. If the N_2 supply is limited by lack of sufficient supply channels, the reaction slows down and becomes irregular resulting in the formation of cold wall zones with incomplete conversion. Temp.-pressure relationships show that the vacuum created by the reaction increases with increasing reaction temp. The differential equation for the heat of reaction is derived from a heat balance and the quantity calcd. as 330 kg.-cal./kg. Many figures, graphs and data are given. 8

Karl Kaminermeyer

Rapid methods for heavy nickel plating. Louis Weisberg. *Monthly Rev. Am. Electroplaters' Soc.* **26**, 929–36 (1939).—For rapid nickel plating a Watts-type bath may be used: 32–48 oz./gal. of $NiSO_4.7H_2O$; 6 of $NiCl_2$; and 4 of boric acid. The operating conditions are: c. d. up to 150 amp./sq. ft. with agitation, or 60 amp./sq. ft. without agitation; temp. up to 180°F. Soft deposits (Brinell, 150) are obtained at a pH of 2 and medium hard deposits at a pH of about 5. Harder deposits may be obtained by adding not over 1 oz. of $(NH_4)_2SO_4$ per gal. of bath and maintaining the pH at 5.2. A modified Ni bath is recommended, which is made by adding Ni for- 9

mate, 6 oz./gal. and formaldehyde, 0.3 oz./gal., to the above Watts-type bath. With this bath, hard deposits can be obtained at a lower pH, and the hard deposits are more ductile than those from the Watts-type bath contg. added NH_4 salts. Pitting seldom if ever occurs in the formate bath. To overcome stress and buckling in deposits, certain naphthalenesulfonic acids may be added to the bath. A. Brenner

Bright nickel deposits—their structure and properties. A. W. Hothersall and G. E. Gardam. *Metal Ind.* (London) **55**, 455-8, 493-6(1939). L. H. Seabright

A suggested basis for specifications of electroplated coatings of nickel and chromium. A. W. Hothersall. *J. Electrodepositors' Tech. Soc.* **15**, 195-204(1939); cf. *C. A.* **33**, 2418[7].—The British Non-ferrous Metals Research Assoc. (BNF) has suggested specifications to assist their members in framing their own detailed specifications. These specifications cover the requirements for decorative or protective electrodeposited coatings of Ni and Cr on steel or on Cu alloys contg. more than 50% Cu. The coatings must be free from imperfections such as blisters, pits, cracks, etc. Three qualities of Ni plating are specified and they differ with respect to the min. thickness of coating on a significant surface.

Quality	Service conditions	Minimum thickness of undercoating (inch): On Brass (Nickel)	On Steel (Ni or Ni-Cu-Ni or Bronze-Ni)
A	Mild	0.0002	0.0004
AA	General	0.0004	0.0008
AAA	Severe	0.0006	0.0008

The average thickness of coating would usually be 2 or more times the minimum thickness. The porosity of AAA quality plating, as detd. by the ferricyanide test, should be less than 6 pores/sq. ft. Cr should always be applied over a Ni undercoating and should have an av. thickness of 0.00002 in. for qualities A and AA and a thickness of 0.00004 in. for the AAA quality. It is suggested that significant surfaces be defined as surfaces which can be touched by a ball 0.75 in. in diam. The BNF jet test is suggested as a min. thickness test for Ni coatings. A sample fails if the coating falls below the required min. thickness at 2 points more than 0.5 in. apart. The thickness test for Cr consists in measuring the time required for a reagent (20 g. of Sb_2O_3 in 1 l. of HCl of sp. gr. 1.16) to dissolve the Cr coating. A. Brenner

Simple methods for plating-solution analysis. Paul A. Oldam. *Monthly Rev. Am. Electroplaters' Soc.* **26**, 851-9(1939).- A review. A. Brenner

Polarization during the electrodeposition of tin from acid solutions of its simple salts. M. Loshkarev, O. A. Esin and V. Sotnikova. *J. Gen. Chem.* (U. S. S. R.) **9**, 1412-22(1939).—Measurements were made of the polarization during cathodic deposition and of anodic soln. of Sn in acid solns. of $SnCl_2$ and $SnSO_4$ by use of the direct compensation method with a mirror galvanometer. The deviations of the polarization values in parallel expts. were 0.2-0.3 mv. for solns. without any addns. and 0.3-0.5 mv. for solns. with addns. for small c. d. At high c. d. in com. baths the deviations were greater, but did not exceed 10 mv. For moving Hg cathodes the reproducibility was 2-3 mv. for pure Hg and 1 mv. for the Sn amalgam. The observed small polarization in $SnCl_2$ and $SnSO_4$ solns. can be almost completely overcome by agitating the electrolyte. This polarization is a result of the slow diffusion of Sn^{++} in the electrolyte. Volts *vs.* c.-d. curves are given for the deposition of Sn from acid solns. ($SnSO_4$, H_2SO_4, glue, cresolsulfonic acid, H_2O). A high polarization voltage is observed in the presence of cresolsulfonic acid. The first part of the voltage *vs.* c.-d. curve (up to the "limiting" c. d.) can be expressed by the equation for the concn. polarization if a sufficient amt. of the cresolsulfonic acid is present. The second part of the curve (beyond the "limiting" c. d.) can be satisfactorily expressed by the equation $\eta = a - b \log (i - i_n)$ where η is the polarization, i is the total c. d. and i_n is the "limiting" c. d. Analogous expts. with moving Hg cathodes were performed. Results supported the previous conclusions. Ten references.

Influences affecting the use of spray rinsing facilities. J. D. Tierney. *Monthly Rev. Am. Electroplaters' Soc.* **26**, 937-46(1939).—A discussion of the advantages of the spray-rinse method over the still rinse tank. A. B.

Anodic treatment of aluminum. Henry A. Smith. *Monthly Rev. Am. Electroplaters' Soc.* **26**, 843-50(1939).—A review. A. Brenner

The platinum electrode. VII, VIII. The effect of poisoning on the capacity of the platinum electrode. A. Slygin and B. Ershler. *Acta Physicochim. U. R. S. S.* **11**, 45-58(1939)(in English); cf. *C. A.* **32**, 3271[6].—S. and E. detd. the amts. of H_2 adsorbed on variously poisoned platinized and smooth Pt electrodes. The exptl. data are shown graphically in 11 figs. Small amts. of Hg and As are adsorbed on the most active spots. With further addn. of poison, KCN lowers the adsorption potential of H_2 (similar to the effect of reversibly adsorbed Br ions), $HgCl_2$ leaves the shape of the isotherm unchanged, As increases the binding energy. At low concns. the relative poisoning effects are: As = 4, KCN = 10, Hg = 40 atoms of H per mol. of poison. Poisoning effects of Hg and As on smooth and on platinized Pt show almost quant. agreement. The decrease of adsorption of H_2 after poisoning is due to a certain specific effect of interaction and not to mere blocking of the surface. F. H. Rathmann

Hydrogen overvoltage on nickel. P. Lukovtsev, S. Levina and A. Frumkin. *Acta Physicochim. U. R. S. S.* **11**, 21-44(1939)(in English).—The H overvoltage on Ni in HCl solns. from 0.0006 to 0.15 *N* and for c. d. from 10^{-5} to 10^{-4} amp./sq. cm. obeys Tafel's equation $\eta = a + b \log i$ with $b = 0.100$. In NaOH, concns. from 0.001 to 8.8 *N*, $b = 0.108$-0.115 at 20°. In acid solns. the overvoltage increases on addn. of neutral salts (NaCl, $LaCl_3$); in alkalies, it decreases. A satn. current similar to that predicted by Horiuti and Okamoto (*C. A.* **32**, 4861[9]) was observed only at much higher c. ds., and can be more satisfactorily explained as due to concn. polarization of H and to the oxidation of Ni and not by the velocity of H adsorption. The exptl. results can be explained by assuming that the slow process is ionic and influenced by the elec. field of the double layer. F. H. Rathmann

Activation process and the nature of the active centers in electrocatalytic hydrogenation. V. V. Monblanova, N. I. Kobozev and P. S. Filippovich. *J. Phys. Chem.* (U. S. S. R.) **13**, 326-40(1939).—Data are given for the electrocatalytic hydrogenation of cinnamic acid at electrodes with large (Cu, Ag, Hg, Pb, Sn) and small (Pt, Fe) H overvoltages; and in the presence of catalyst poisons such as K_3AsO_4 and $HgCl_2$. The "poisons" poison the first group of metals and activate the second up to a certain max. concn., 1×10^{-5} mols./l. in alkali, 6×10^{-4} in acid for $HgCl_2$ on a Pt cathode and 1×10^{-4} mols./l. for K_3AsO_4 on an Fe cathode, from which the Kobosev (cf. *C. A.* **33**, 7654[3]) "active ensemble" could be calcd.: 2.1-2.4 for Pt, 2.0 for Fe. In this case the active centers have a lowered adsorption potential due to the effect of the "poison." On a clean Pt cathode the energy of activation between 0° and 51° is 5.95 cal., on a Hg film 1.5 mol. thick 2.32, and on an amalgamated Pt cathode 1.21 cal./mol. Comparison of the effects of poisoning of polarized surfaces of smooth and of platinized platinum indicates that they are essentially the same. On Ag and Cu cathodes no reduction takes place with or without the presence of a "poison." Exptl. data are tabulated in 10 tables and 7 figs. The Erdey-Gruz-Volmer and the Bowden-Rideal conceptions of electrode processes are not applicable to electrocatalytic reduction. F. H. R.

Overvoltage of silver. A. T. Vagramyan. *J. Phys. Chem.* (U. S. S. R.) **13**, 311-17(1939); cf. *C. A.* **33**, 6169[1].—Data are given for the Ag-$AgNO_3$ electrode in a N_2 atm. On closing the circuit, the cathode polarization is high, then decreases to a nearly const. value, the less the greater the concn. of the electrolyte, and varying also with the purity of the soln. Above 6 *N* $AgNO_3$ (3 cryst. deposit

nuclei), especially if impure, the value of the stable cathode polarization varies by only 0.5 mv. on changing the current from 10^{-5} to 10^{-6} amp.; below 0.1 *N* $AgNO_3$ (70 nuclei), esp. in pure solns., it increases considerably. Temporarily the polarization increases considerably on increasing the current, and vice versa, but then slowly, and in 20–40 min. reaches a stable value. These facts cannot be explained by the present Erdey-Gruz and Volmer theory. F. H. Rathmann 1

Overvoltage of hydrogen on lead. B. Kabanov, S. Filippov, L. Vanyukova, Z. Iofa and A. Prokof'eva. *J. Phys. Chem.* (U. S. S. R.) 13, 341–9(1939).—See *C. A.* 33, 2044. F. H. Rathmann 2

Electrochemical potential and Volta effect. I. O. Scarpa. *Atti accad. Lincei, Classe sci. fis., mat. nat.* 29, 141–51(1939).—The Volta effect (potential difference between 2 metals in contact) cannot always be ignored when measuring metal electrode potentials. A list of such potentials for the more common metals is given. A. W. Contieri 3

Role of electrons in producing the electromotive force at the metal-electrolyte contact. N. Vasilesco-Karpen. *Compt. rend.* 209, 474–6(1939).—In voltaic cells metal and electrolyte are regarded as immiscible liquids of different dielec. consts. and contg. metal cations of concns. M and M' in metal and electrolyte, resp., and free electrons of concns. E and E'. The valence of the metal is n. The energy θ_m of an equiv. of cation in the interior of the metal is less than that, θ_e, in the electrolyte, the difference $\theta = \theta_e - \theta_m$ being the work required to remove the cation from metal to electrolyte; similarly to remove an electron the necessary energy is $\tau = \tau_e - \tau_m$. The p. d. produced by exchange of cation between metal and electrolyte is $V_1 = \theta - (RT/n) \log (M/M')$, and similarly for the electron $V_2 = -\tau + RT \log (E/E')$. V_1 should equal V_2, but usually does not do so. If, e. g., V_1 is greater than V_2, electrons and cations will pass between metal and soln., reducing the concn. in the metal to $M - x$ and $E - nx$ until the potential becomes $V = \theta - (RT/n) \log [(M - x)/(M' + x)] = -\tau + RT \log [(E - nx)/(E' + nx)]$. In the soln. the electrons and cations recombine to metal. *Ibid.* 509–11. V.-K.'s views are applied to the Daniell cell in which x is small compared with M, E and M'. C. A. Silberrad 4

Electron concentration cells and measurement of pH. N. Vasilesco-Karpen. *Compt. rend.* 209, 790–2(1939); cf. preceding abstr.—The case is considered of cells composed of identical electrodes of nonattackable metal in 2 electrolytes touching each other and contg. no cations of the metal; which according to the author's theory are electron-concn. cells. C. A. Silberrad 5

Electrolytic preparation of iron and steel microspecimens. G. E. Pellissier, Jr., Harold Markus and Robert F. Mehl. *Metal Progress* 37, 55–6(1940).—Steel specimens finished with 000 emery were polished electrolytically in an aq. electrolyte contg. acetic acid and perchloric acid. Modified electrolytes and elec. conditions are given for Sn, Cu, Co, Al, Zn, Pb, brass and bronze. Illustrating photomicrographs at 100 to 2500 magnification are included. W. A. Mudge 6

Galvanic action, particularly in corrosion. W. P. Jorissen. *Chem. Weekblad* 36, 832–4(1939).—A review covering the period from the 18th century (Galvani, Volta) to the present. 36 references. A. H. Krappe 7

Backing and steel-facing zinc plates. A. G. Arend. *Process Engraver's Monthly* 45, 369–70(1938); *Phot. Abstracts* 19, 50.—Zn plates are "steel-faced" by depositing first a thin film of Cu and then a coating of Fe. Successful facing depends upon a high Fe^{++} concn. at the cathode, low acidity, high temp., the presence of chlorides and freedom from org. matter. H_2 is absorbed by charcoal suspended in the bath. An acid-resisting backing can be applied by depositing a steel similar in compn. to "Staybrite." The same Fe bath can be used with the addn. of Ni and Cr. 8

An apparatus for electrodialyses and preparation of organic sols and gels. Olle Dahl. *Svensk Kem. Tid.* 51, 219–25(1939)(in English).—A glass cylinder of about 800 cc. capacity is placed between 2 electrode compartments made of wooden blocks. The wood compartments are separated from the glass cylinder by a cellophane membrane at the anode end of the cylinder and by parchment at the cathode end. Electrodes are made of stainless steel wire gauze disks. Ag wire cannot be used. Glass tubes pass into the wooden compartments so as to have water circulate through them, also to remove accumulating gases. The glass cylinder has a feed tube through which the material to be electrodialyzed is introduced. The wooden parts are impregnated with paraffin. A 220 v. current is applied at the beginning of the electrodialysis giving about 40 milliamp. which gradually drops to 4 and remains constant; 440 v. may then be applied. A. R. Rose 9

Piezodynamic proof of the Gladstone-Tribe theory of the mechanism of the lead storage battery. Ernst Cohen and G. W. R. Overdijkink. *Proc. Acad. Sci. Amsterdam* 42, 834–48(1939).—Within exptl. error the mechanism of the Pb battery is described by the Gladstone-Tribe sulfate theory, $2PbSO_4 + 2H_2O \rightleftharpoons Pb + PbO_2 + 2H_2SO_4$. The vol. change due to the supply of current and with the passage of 2 faradays was detd. The mol. vol. of the solid substances was detd. by means of x-rays. The pressure coeff. of the e. m. f. at 0° = -3.07×10^{-6} = 0.038×10^{-6} v./atm. W. George Parks 10

Lamps: electric, incandescent, large, tungsten-filament. *Federal Specification* W-L-101d, May 2, 1939. **Batteries, storage: ignition, lighting, and starting.** *Ibid.* W-B-131b, Apr. 4, 1939. Washington: Supt. of Documents, U. S. Govt. Printing Office, 5¢ each. L. W. Greene 11

Electroconvective vortexes in smoke-laden air. Douchan Avsec. *Compt. rend.* 209, 869–71(1939); cf. *C. A.* 34, 1159⁴.—A layer of tobacco smoke 2–5 mm. thick was arranged along the bottom of a glass chamber 110 cm. long and of cross section 45 × 2 to 6 cm. thick. The vortexes formed on applying an electrostatic field of at least 1000 v./cm. are described. C. A. Silberrad 12

Cleaning of air and gas by thermal repulsion [elec. heating in] (Blacktin) **1**. Elec. method for end-point detns. in jet test for thickness of metal plating (Lindsey, Terrett) **9**. Heat-treatment of metal filaments [for incandescent lamps] (U. S. pat. 2,179,367) **9**. Elec. heating of flowing molten glass [use of elec. resistor] (U. S. pat. 2,179,224) **19**.

Storage-battery paste. Robert A. Daily (to General Motors Corp.). U. S. 2,178,680, Nov. 7. A Ni salt of sulfonated lignin is used as an expander.

Storage-battery venting device. Stewart C. Aikenhead (to Willard Storage Battery Co.). Can. 385,264, Nov. 21, 1939. Structural details

Dry cell. Paul A. Marsal (to Canadian National Carbon Co., Ltd.). Can. 385,324, Nov. 28, 1939. Operative and structural details.

Dry electrolytic condenser. James M. Booe and Charles M. Blackburn (to P. R. Mallory & Co.). U. S. 2,177,819, Oct. 31. A flexible sheet electrode for dry electrolytic condensers comprises a cloth base and finely divided film-forming metal such as Al deposited on the base the metal particles cohering to provide a conducting path along the electrode layer and the electrode being sufficiently open-mesh and porous to permit light to pass through the electrode layer at a multiplicity of distributed points throughout its area. Such electrodes give relatively high capacity.

Vent for electrical condensers. Alexander M. Georgiev and Paul F. Koehly (to General Motors Corp.). U. S. 2,178,686, Nov. 7. Various structural details, including

a vent with a wall member having an aperture therethrough ending in a countersink, and a celluloid soln. residue sealing the aperture against free flow around a closure which is provided.

Venting cap for electrolytic devices such as condensers. Joseph L. Collins (to Sprague Specialties Co.). U. S. 2,174,437, Sept. 26. Structural details.

Oxide film on aluminum used for electric condensers. V. I. Likhov. Russ. 51,902, Oct. 31, 1937. The oxide film is obtained by anodic oxidation at elevated temp. and under pressure.

Dry electrolytic capacitors. Samuel Ruben. U. S. 2,178,970, Nov. 7. Between elements such as electrode foils, a spacer is used comprising a layer of fibrous material such as paper sized with a plasticized, conductive, flexible, nonviscous methyl cellulose compn. comprising a membrane in the fibrous layer.

Potential producing cell. Samuel Ruben. U. S. 2,178,969, Nov. 7. A neg. electrode such as a Zn or Cd disk and a pos. electrode such as a V_2O_5 disk are used with a contacting electrolyte such as one formed of ethylene glycol, boric acid and NH_3 soln. all of which are sealed together in a shell of molded resin such as a synthetic resin.

Electroplating with stainless iron. Miklós Kalocsay. Hung. 122,063, Nov. 15, 1939. Anodes of a stainless Fe alloy or steel are used in a bath contg. the components of this metal as cations; other metals or ions, especially citric acid, may be present. Potential of 4 v. and c. d. of 3.5 amp. per sq. dm. are used.

Gold-plating grids for electric discharge tubes. Egyesült Izzólámpa és Villamossági R. T. Hung. 121,761, Oct. 16, 1939. Gold is electrodeposited in several layers, and the grid ignited in a neutral-gas atm. after each layer is deposited.

Barrel electroplating apparatus. Albert H. Hannon. U. S. 2,177,982, Oct. 31. Various structural, mech. and operative details.

Calcium silicide. M. A. Varzanov, A. S. Negovskiĭ and Ya. I. Izrailovich. Russ. 51,983, Oct. 31, 1937. To prep. $CaSi_2$, a mixt. of SiC, CaC_2 and quartz is fused in the elec. furnace.

Apparatus suitable for etching printing plates in an electrolytic bath. Harry G. Pfaffmann (to Burger-Baird Engraving Co.). U. S. 2,177,877, Oct. 31. Various structural, mech., elec. and operative details.

Electrostatic heating system suitable for heating nonconducting molding materials. Arthur C. Meller (to Bell Telephone Laboratories, Inc.). U. S. 2,179,261, Nov. 7. Various structural, elec. and operative details.

Electrode clamp suitable for use with electric furnace electrodes. Robert R. Jones (to Ohio Ferro-Alloys Corp.). U. S. 2,179,153, Nov. 7. Various structural details.

Oxide cathodes. Egyesült Izzólámpa és Villamossági R. T. Hung. 122,130, Nov. 15, 1939. A metal wire (e. g., tungsten) is led through an aq. suspension of the substance that is to be applied to its surface. Various org. substances (e. g., sucrose or glucose) are dissolved in this suspension so that on ignition not more than 0.1% carbon should be formed on the metallic surface. This first coating is dried at 200–450°, the wire is treated with a soln. of the same substances in nitrocellulose and the procedure is repeated. Cf. *C. A.* **33**, 2824[6].

Thermionic cathode. Victor O. Allen (to Radio Corp. of America). Can. 384,608, Oct. 10, 1939. A thermionic cathode for use in an electron-discharge device consists essentially of W contg. Th electrolytically coated with Cr.

Cooled contact rectifier. Carl C. Hein (to Westinghouse Elec. & Mfg. Co.). U. S. 2,179,293, Nov. 7. Various structural details of a rectifier having a plate contact member such as one of Cu with an adjoining metal member carrying a layer of electronically conductive compd.

Grids for rectifier tubes. Egyesült Izzólámpa és Villamossági R. T. Hung. 121,762, Oct. 16, 1939. The base metal of the grid is coated with a metal or an alloy that will form an alloy with Au (e. g., Ni or Ni alloys), and then a Au plate is applied. The grid is finally heated to alloy the Au with the intermediate layer.

Electric resistors. Knox C. Black and Royer R. Blair (to Bell Telephone Laboratories, Inc.). U. S. 2,178,548, Nov. 7. A method of making a resistor involves welding terminal conductors to the ends of a length of fine Ag wire, heating the wire in S vapor to sulfidize it, drawing the wire and terminal conductors into a capillary glass tube, placing a heating coil about the exterior of the tube and mounting the unit thus formed in an evacuated envelope such as a glass tube.

Electric resistor unit. Charles J. Ganci (to Ward Leonard Elec. Co.). U. S. 2,179,212, Nov. 7. A ceramic base carries a resistive conductor such as wound Ni-Cr-Fe alloy wire over which is placed an enamel coating having a coeff. of expansion lower than that of the ceramic base, the latter having a coeff. of expansion of 50–75% that of the resistive conductor.

Photoelectric exposure meter. Joseph M. Bing. U. S. 2,178,197, Oct. 31. Various structural details.

Gas treatment. Harry A. Wintermute (to International Precipitation Co.). Can. 384,289, Sept. 26, 1939. A gas is passed through a high tension elec. field maintained between opposed complimentary electrodes and an extended stream of liquid particles is projected into the gas without coming into contact with the electrodes. The process is used for cleaning gases, for removing water from a tar emulsion by means of hot gases or aerating sewage. An app. is described.

Grid for screening-off scattered x-rays. Gustav A. Lindstedt and Ernst H. Öhrn (to Aktiebolaget Linham). U. S. 2,178,798, Nov. 7. A thin sheet of Pb is coated with a layer of fibrous material such as paper and the composite sheet thus formed is cut into narrow strips which are assembled side by side to form the grid.

Electrodes for television tubes. John L. Gallup (to Radio Corp. of America). U. S. 2,175,689, Oct. 10. A mosaic electrode includes an enameled perforated base of material such as Ni and a vitrified enamel coating completely covering the base to provide apertures having enameled walls, the enamel consisting of an alkali lime glass base contg. 8–15% B_2O_3, m. about 900° and having an elec. resistivity of about 1×10^{13} ohm cm., and metallic plugs contg. Ag fitted into the apertures.

Insulating films for picture-transmitting tubes. Emanuel R. Piore (to Radio Corp. of America). U. S. 2,178,081, Oct. 31. In a tube having a mosaic structure and means for producing an electron beam and for directing it toward the mosaic structure, the latter is formed with an electrically conducting surface having on it an insulating film of a material comprising B_2O_3, which supports a multitude of electron-emissive elements or globules supported on the film and insulated from each other.

Electric discharge devices. Walter Hanlein, Wilhelm Hagen and Hermann Krefft (to Canadian General Electric Co., Ltd.). Can. 385,194, Nov. 21, 1939. The device contains a gaseous atm. and sealed electrodes, and is formed of a glass consisting of SiO_2 about 82.5%, Al_2O_3 10, CaO 3.75 and BaO 3.75%.

Vapor electric device suitable for arc discharge. Adolph H. Toepfer (to Westinghouse Elec. & Mfg. Co.). U. S. 2,179,310, Nov. 7. Various structural details of a device having a container of quartz tubing or the like contg. loose particles of high-resistance material such as B carbide portions some of which protrude from a slitted opening in a lower portion of the container into contact with a conductor such as Hg.

Cathode for electron-discharge devices. Emil G. Widell (to Radio Corp. of America). U. S. 2,179,110, Nov. 7. In a device such as an amplifier, a cathode of substantially pure Ni contg. 0.02–0.05% of C is used with a coating of alk. earth oxides (the Ni being free of impurities which would reduce the oxides).

Gaseous electric discharge device for emitting ultraviolet radiations. Alfred Rüttenauer (to General Elec. Co.). U. S. 2,178,436, Oct. 31. On the interior surface of the container of a Hg-vapor lamp or the like, a coating is used consisting of Mn-activated Cd silicate and Sm-

activated Ca tungstate and which avoids loss of luminosity such as occurs when ZnO is used.

Electric discharge device suitable for making visible the paths of electrons. Ernest A. Massa and Geo. A. Morton (to Radio Corp. of America). U. S. 2,178,238, Oct. 31. Various details are described of a device having a fluorescent screen comprising an insulating supporting surface such as mica or glass having on it Ag globules sensitized with an alkali metal and having only a portion of the globules covered with minute particles of fluorescent material such as willemite substantially uniformly distributed over the screen surface.

Luminescent mixture suitable for use with electric discharge tubes. Marcel Servigne (to Société pour l'étude & l'exploitation des materiès luminescentes). U. S. 2,179,134, Nov. 7. Tri-Ca orthophosphate 75, Pb molybdate 5, Ca molybdate 20 parts and Li_2O 0.25 part or the like are used together.

Coating the interior surface of luminescent glass tubes with materials such as fluorescent compositions. Theodore W. Frech (to General Elec. Co.). U. S. 2,179,288, Nov. 7. Various details of app. and operation.

Removing gases from enclosures such as electric discharge tubes. Jean Lecorguillier (to Soc. anon. pour les applications de l'électricité et des gaz rares, établissements Claude-Paz & Silva). U. S. 2,178,326, Oct. 31. A process for removing gases evolved from electrodes of a gaseous elec. discharge tube during its manuf. involves circulating Hg unidirectionally in a closed circuit including the discharge tube, successively converting the Hg from liquid to vapor state in a sep. vaporizing receptacle, passing it through substantially the whole longitudinal section of the discharge tube in the vapor state, condensing it by passing downward through a cooled condensing chamber and returning it as liquid to the vaporizing receptacle, while causing the gases to flow in the same direction as the condensed liquid, and sucking them from the closed circuit at a point between the condensing chamber and the vaporizing receptacle.

Electric discharge lamp. Willem Uyterhoeven (to General Elec. Co.). U. S. 2,177,755, Oct. 31. An elec. lamp comprises in combination a gaseous elec. discharge lamp device of the type operating with an elevated container temp., a heat conservator in which the lamp device is mounted and which has a heat dissipating part, a coating of heat-sensitive, luminescent material such as ZnS in the conservator in light-receiving relation to the lamp device and remote from the heat-dissipating conservator part, and a gaseous filling such as N in the conservator at a pressure such that the heat emitted by the lamp device during its operation causes convection currents in the gas to transfer the heat from the lamp to the heat-dissipating part of the conservator to increase the useful life of the luminescent material.

Flash lamp. Richard S. Mackie (to General Elec. Co.). U. S. 2,178,430, Oct. 31. A flash lamp with a sealed container contg. combustible material such as Al foil is provided with an igniter comprising a bead of highly sensitive fulminating substance (such as Zr, PbO_2 and a lacquer binder) coated with a synthetic-resin mixt. or the like. Cf. *C. A.* **33**, 2826[7].

Electric incandescent lamp. Arthur R. Socolofsky U. S. 2,179,437, Nov. 7. A W filament is used with inert gas such as A or N and active gases such as WCl_6 which set free W atoms operating to compensate evapn. of the filament.

5—PHOTOGRAPHY

E. R. BULLOCK

Hundredth anniversary of the discovery of photography. A. Rabinovich. *Uspekhi Fiz. Nauk* **21**, 478–80 (1939).—A brief historical review. F. H. Rathmann

Recent developments in color photography. D. A. Spencer. *J. Roy. Soc. Arts* **88**, 163–75(1939). E. H.

The photographic reciprocity law at low temperature. C. H. Evans and E. Hirschlaff. *J. Optical Soc. Am.* **29**, 164–7(1939); cf. *C. A.* **32**, 7837[6].—The results of measurements of reciprocity law failure at 20° and at −186° are given for 2 different high-speed panchromatic emulsions, 1 low-speed unsensitized emulsion and 1 high-speed orthochromatic emulsion. These measurements, covering the range in exposure time from 1/16 sec. to 1024 sec., show that in each case the reciprocity law failure, at both high and low intensity, is normal at 20°, but has disappeared entirely at −186°. These results are in complete agreement with those recently published by Berg and Mendelssohn (*C. A.* **33**, 1608[9]). Authors

Chemical analysis of an M.-Q. developer. Ralph M. Evans and Wesley T. Hanson, Jr. *J. Soc. Motion Picture Engrs.* **32**, 307–20(1939); cf. *C. A.* **33**, 1228[6].—The maintenance of developer activity over a long period of time is among the most important problems of a motion-picture lab. The developer is oxidized by the Ag halide in the emulsion and by air. When known amts. of these 2 oxidizing materials react with the developer, simple calcns., which were presented in a previous paper (*C. A.* **33**, 4536[5]), are sufficient to det. the equil. condition of the developer as well as the replenisher formula to give a chosen equil. Under ordinary conditions, there are large variations in the amt. of developer oxidation. A chem. analysis immediately detects any deviation from the correct equil. and permits readjustment of the replenisher formula. Chem. analyses are presented which require a min. of equipment and time. In most cases, ease of manipulation and speed have been considered as more important factors than a high degree of accuracy but in all cases the methods are capable of giving results to an accuracy of 5% or better. Whenever possible, the analyses are colorimetric in nature, the measurements being made on an instrument called an opacimeter (cf. *C. A.* **34**, 1209[9]). One operator can make a complete analysis in about 30 min. Analysis for any one constituent may be made in a much shorter time. It is emphasized that no one control variable is significant for specifying the activity of a developer. Sensitometric curves are included demonstrating the time lag in pH equil. but not in photographic equil. when hydroxide is added to or released in the developer. The aim of chem. control is to insure a const. condition of the developer and thus const. photographic quality, rather than to det. the degree of development. Authors

Use of color-coupling developers for toning processes. K. Famulener. *J. Soc. Motion Picture Engrs.* **32**, 412–18 (1939).—Some expts. on the toning of motion-picture pos. film by the methods of direct dye-coupling color development, which have heretofore been applied principally to natural color processes, are described. Methods of obtaining a wide range of colors and of controlling contrast are also discussed. Author

Making duplicates from miniature negatives. I, II. Heinrich Stoeckler. *Miniature Camera Mag.* **3**, 129–30, 228–30(1939); cf. *C. A.* **33**, 8512[9].—Two articles deal with the production of duplicate negatives on special duplicating films, such as are marketed by Agfa, Kodak and Perutz. Procedures and formulas are given. M. D. G.

Color printing by photogravure. H. Mills Cartwright. *Phot. J.* **79**, 436–8, 449(1939); cf. *C. A.* **33**, 5759[1].—The photogravure process is described with special reference to the methods employed for color printing. Color correction, types of original and proofing are discussed. R. F. W. Selman

Ozaphane sound film. A. Narath. *Kinotech.* **20**, 232–7 (1938); *Phot. Abstracts* **19**, 66.—The Ozaphane film using cellophane base gives direct positives after development with NH_3 gas. The grainless image is warm black; a d. of 2.42, measured visually, has a d. of only 0.45 to a Cs photocell densitometer. The sensitive layer is thicker (47 or 65 μ) than that of a normal Ag halide emulsion (10–15

μ), and as a result sound tracks show losses at high frequencies. With variable-width methods a slight loss in amplitude occurs. Satisfactory copies can be obtained with the Ozaphane film, the nonlinear distortions caused by diffusion in the sensitive layer being not more important than those produced in Ag halide emulsions.

Mack, Julian Ellis, and Martin, Miles J.: The Photographic Process. New York: McGraw-Hill Co. 586 pp. $5.00. Reviewed in *J. Applied Phys.* 11, 71-2 (1940).

Color photography. John Eggert, Alfred Fröhlich and Bruno Wendt (to Agfa Ansco Corp.). U. S. 2,179,228, Nov. 7. A light-sensitive material for color photography comprises a support such as a film carrying a Ag halide gelatin emulsion contg. an org. colorless dye component such as 2,3-hydroxynaphthoic acid dianisidide capable of reacting with a further component such as *p*-diphenylaminediazonium sulfate to produce a dye image, the first component being of a chem. character imparting to it substantive properties with respect to the gelatin. Several examples are given.

Color photography. Gustav Wilmanns, Wilhelm Schneider and Ernst Bauer (to Agfa Ansco Corp.). U. S. 2,179,238, Nov. 7. A light-sensitive material for color photography comprises a Ag halide emulsion contg. a dye component for color-forming development, such as an acetoacetic ester having attached to it a group which gives the component substantive character with respect to the binding agent of the Ag halide emulsion and also contg. a compd. such as diphenylguanidine having a pptg. action on the dye component. U. S. 2,179,239 relates to a photographic emulsion layer having incorporated in it a color-forming development component, such as one contg. the benzothiazole grouping, which has linked to an atom of its mol. a substantive grouping of so large a number of C atoms that the mol. size of the component is materially increased, the grouping rendering the component fast to diffusion.

Color photography. Wilhelm Schneider and Alfred Fröhlich (to Agfa Ansco Corp.). U. S. 2,179,244, Nov. 7. Use is made of a Ag halide gelatin emulsion contg. a dye component such as an α-hydroxynaphthoic acid reaction product which is fast to diffusion and capable of forming a dye of the group of quinoneimine-, azomethine- or azo dyes, and which is a polypeptide of a color former.

Color photography. Gustav Wilmanns and Wilhelm Schneider (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,229, Sept. 26, 1939. Multilayer photographic material having several superposed Ag halide emulsion layers contg. dyestuff components fast to diffusion is exposed, the formed latent image developed with a black-and-white developer, fixed, the formed Ag reconverted to a Ag salt capable of being developed and the Ag salt redeveloped successively with several color-forming developers that react with different speeds with the dyestuff components contained in the layers.

Color photography. Gustav Wilmanns and Wilhelm Schneider (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,384, Oct. 3, 1939. A colored transparency to be viewed in reflected light comprises a support, several Ag halide emulsion layers for a multicolor picture on one side of the support, and a panchromatic layer for a black-and-white picture on the other side. The black-and-white picture faces the camera objective and is developed as a dyestuff picture or directly as a Ag picture.

Color photography. Wilhelm Schneider (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,668, Oct. 17, 1939. A light-sensitive element consists of a support and several differently sensitized Ag halide emulsion layers consisting of a blue-sensitive layer having a sensitive range of about 400–80 mμ with a max. of about 430–60 mμ, a green-sensitive layer of sensitive range about 460–610 mμ with a max. at 540–55 mμ, and a red-sensitive layer of sensitive range about 500–670 mμ with a max. at about 500–630 mμ.

Color photography. Wilhelm Schneider (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,669, Oct. 17, 1939. In producing colored prints from subtractive master pictures, a multilayer, color-photographic, light-sensitive element sensitized with dyes corresponding substantially with the absorption maxima of the picture dyes of a master picture is illuminated through the master picture and a series of filters which absorb the wave lengths of the light corresponding to the overlapping regions of the picture dyes of the master picture.

Color-photographic material. Gustav Wilmanns (to Agfa Ansco Corp. (a Delware corp.)). Can. 384,383, Oct. 3, 1939. A color-photographic material to be viewed in reflected light comprises an opaque support, several differently sensitized emulsion layers with dye components fast to diffusion, and an antihalation layer contg. finely divided pyrolusite as an absorbing medium arranged between the support and layers.

Bi-pack for color photography. Bruno Wendt (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,667, Oct. 17, 1939. One support bears two superposed, differently sensitized Ag halide emulsion layers and another bears a single Ag halide emulsion layer, the layers being in contact with one another, and the two superposed layers contain a dyestuff fast to diffusion.

Emulsion for color photography. Wilhelm Schneider and Alfred Fröhlich (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,382, Oct. 3, 1939. The emulsion contains a dye component fast to diffusion with respect to the gelatin. The dye component contains a carboxylic acid radical linked to the amine group of a polypeptide and is capable of forming a quinoneimine, an azomethine or an azo dye *in situ* with a Ag picture on contact with a color-forming developer.

Photographic emulsion. Walter Zeh (to Agfa Ansco Corp.). Can. 384,086, Sept. 19, 1939. A Ag halide emulsion contains a dyestuff consisting of at least 2 nitrogenous heterocyclic nuclei, the nuclei joined by at least one methine group, with at least one of the nuclei being a 2-alkyltetrahydrobenzothiazole or a 2-alkyltetrahydrobenzoselenazole. Many examples are described for the prepn. of the dyestuffs.

Photographic emulsion. Frank L. White and Grafton H. Keyes (to Canadian Kodak Co., Ltd.). Can. 384,241, Sept. 26, 1939. Many examples are described of hemicyanine dyes for incorporation in Ag halide emulsions. Novel sensitivity is produced and the concn. of the dyes in the emulsions is about 5–100 mg./l. of flowable emulsion.

Photographic emulsions on textiles. P. N. Engelblik. Dutch 46,703, Sept. 15, 1939. Melted light-sensitive emulsions are applied to fabrics and rubbed in; the tissue may be pretreated successively with a $KMnO_4$ soln. (1%) and a K metabisulfite soln. (10%). The emulsion can be: 65 g. gelatin, 50 g. KBr, 0.5 g. KI, 1.5 l. distd. H_2O and 65 g. $AgNO_3$ heated to 55° for 1 hr., then 0.5 l. H_2O added and 90 g. gelatin, heating continued for 1/4 hr. After solidification the mass is broken up, washed for 1 hr., melted at 30° and 1/8 l. formaldehyde soln. added. A metol-hydroquinone developer and acid fixing bath are advocated.

Photographic silver halide gelatin emulsions containing dye components. Wilhelm Schneider and Max Hagedorn (to Agfa Ansco Corp.). U. S. 2,178,612, Nov. 7. With a Ag halide gelatin emulsion, there is used a dye component fast to diffusion with respect to the gelatin and which may be an amide of a color former with a highly polymeric carboxylic acid capable of forming a dye at the places of the Ag image upon being brought into contact with a color-forming developer such as *p*-aminodimethylaniline.

Light-sensitive layers. Roelof J. H. Alink and Jan H. de Boer (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,178,771, Nov. 7. In mfg., from a diazonium compd. component, a coloring component, and an alk.-reacting substance, a light-sensitive layer capable of image development after exposure merely by the action of moisture and without the addn. or removal of any coem. substance, at least the last-applied of the components is applied in a

powdery state to a dry carrier such as paper to which is also applied an alk.-reacting powder such as Ca silicate and a powder, such as CaO, which yields upon development a hydroxide of low soly. Various examples are given.

Dyeing photographic images. Béla Gáspár. U. S. 2,178,167, Oct. 31. A process of dyeing a photographic image by an azo dye involves incorporating in the light-sensitive Ag halide emulsion used for the production of the image an aromatic nitro or nitroso compd., such as di-(nitrobenzoylamino)-stilbenedisulfonic acid, exposing the layer to light to form a latent image in it, developing to form a Ag image, reducing the N compd. within the layer to an amino compd., as by a 2% Na hyposulfite soln., and synthesizing an azo dye within the layer from the amino compd., as by use of an alk. soln. of β-naphthol.

Photographic fixing and hardening composition. Garnet P. Ham (to American Cyanamid Co.). U. S. 2,179,242, Nov. 7. A product suitable for dissolving in water is formed into solid masses with a core of a hardening component such as alum surrounded by a layer of a fixing component such as Na thiosulfate.

Gelatin printing reliefs. Walter Frankenburger and Georg Rössler (to Agfa Ansco Corp.). U. S. 2,178,338, Oct. 31. A process for the production of a gelatin relief by the H_2O_2 etching method involves exposing a Ag halide gelatin emulsion layer through the support of the layer, developing the latent image, hardening the gelatin proportionally to the developed silver, exposing the layer to diffused light, treating the layer with a developer incapable of affecting the gelatin, and transforming the layer to a relief.

Photographic film. Alfred Miller (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,385, Oct. 3, 1939. On the front of a support are 2 differently sensitized Ag halide emulsion layers and on the rear is a third layer. Each layer contains a dye component fast to diffusion, capable of forming a dye at the places of the Ag image on contact with a color-forming developer. A layer contg. a matting agent is cast on top of the third layer.

Multicolor sound films. Wilhelm Schneider (to Agfa Ansco Corp.). U. S. 2,178,882, Nov. 7. A process of producing multicolor sound films comprises producing a multilayer film having incorporated in the several Ag halide gelatin emulsion layers dye components which, though sol. in aq. liquids, are fast to diffusion and capable of forming dyes with a developer adapted for color development, the several layers being sensitive to different colors, exposing the multilayer film to a color-picture image while protecting a marginal portion of the film for the sound record, developing all the layers in a single process in a developer capable of forming dyes with the dye components, bleaching the produced metallic Ag, printing a sound negative on the marginal portion of the film while protecting the picture portion of the film from further exposure, developing the sound track in a black-and-white developer, and removing all the undeveloped Ag halide still contained in the layers.

Developing photographic films and plates. Alphons O. Jaeger and Joseph E. Jewett (to American Cyanamid & Chemical Corp.). U. S. 2,178,450, Oct. 31. A Ag halide emulsion contg. a latent image is subjected to the action of a chem. developer soln. together with an effective amt., not substantially exceeding 0.25%, of a salt of an ester of an aliphatic sulfo carboxylic acid such as Na dioctyl sulfosuccinate which serves to facilitate uniform distribution of the developer soln.

Photographic sound-track image. Ralph M. Evans and Wesley T. Hanson, Jr. (to Canadian Kodak Co., Ltd.). Can. 385,872, Dec. 26, 1939. A natural-color image and a sound-track image are formed in a multilayer film having three differently sensitized layers on one side of a transparent support by forming a natural-color picture in the film and a sound-track image in at least one layer of the film by development with a *p*-benzylphenol and a *p*-phenylenediamine developing compd.

Sound and picture photographic records. Judd O. Baker (to Radio Corp. of America). U. S. 2,178,217, Oct. 31. A method of sound motion picture production involves recording the sound and picture on a photographic record having a fog d. of the range of 0.38 and a γ of the range of 0.55, printing the sound track into a second record having high-contrast pos. emulsion, a fog d. of the range of 0.02 and a γ of the range of 4, printing the sound from the high-contrast record to a release print, and printing the picture from the photographic record to the release print.

Making photographs. Geo. N. Pifer (to Speedtype, Inc.). U. S. 2,178,896, Nov. 7. App. is described, and a process of producing a photograph which involves applying a developing soln. to the exposed sensitized surface, then applying an acid bleaching soln. and partially removing the bleaching soln., then applying a "hypo" soln., and then, without an intervening washing of the surface and while it is in an acid condition and without exposure to light, applying a developing soln. in the presence of the "hypo" soln. which mixes with the developing soln. and acts as an accelerator for it.

Multicolor photographs. Wilhelm Schneider (to Agfa Ansco Corp.). U. S. 2,179,234, Nov. 7. A process of producing multicolor photographs comprises producing a multilayer film having incorporated in the several gelatin Ag halide emulsion layers a dye component capable of forming a dye with a developer adapted for color development, the dye components although sol. in aq. photographic developing solns. being of such molecular constitution that they are incapable in such dissolved form of diffusing in gelatin in any photographic treating bath, exposing the multilayer film to a colored object, developing the exposed film in a developer not capable of forming a color with the dye components, exposing the multilayer film a second time, simultaneously developing all the layers of the exposed film in a developer capable of forming dyes with the dye components and removing the developed Ag from the film.

Printing multicolor pictures. Wilhelm Schneider (to Agfa Ansco Corp. (a Delaware corp.)). Can. 384,386, Oct. 3, 1939. In printing from a multicolor master picture obtained by color-forming development onto a printing material adapted for color-forming development, a multicolor filter contg. images identical in structure with those of the master film is interposed in the path of the light rays.

Color correction of photomechanical images. Robert L. Klein. U. S. 2,179,014, Nov. 7. A method of controlled color correction of photomech. images involves applying, over those mass tones that are correct, a permanent transparent waterproof and acid-resisting staging compd., etching unstaged tone masses of the image with etching soln. until masses requiring the least etching are corrected, then staging the masses thus corrected with a staging compd. as previously used, and repeating the etching and staging operations as required to correct and protect all tone masses of the image, then photographically copying through the corrected image without removing any of the previously applied staging compd. Various compns. used are described.

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

The properties of liquid amalgams. V. D. Ponomarev and S. M. Gubel'bank. *J. Gen. Chem.* (U. S. S. R.) 9, 1365-8(1939).—0.1 *N* $HgCl_2$ shaken with Zn amalgam for 10–15 sec. was reduced to Hg. $PbSO_4$ was reduced to Pb by Zn amalgam in HCl soln. These results show that liquid amalgams can be used for the decompn. of weakly dissocg., or of slightly sol. compds. which contain an ion whose oxidation-reduction potential

is higher than the potential of the corresponding amalgam. AgCl, AgBr and AgI were completely reduced by Zn amalgam. A decrease of the acidity during the reduction process increased slightly the time of the decompn. of the ppts. The decompn. velocity decreased in the direction from AgCl to AgI. These reactions can be utilized for the detn. of Cl^-, Br^- and I^-. Unsatisfactory results were obtained for the quant. decompn. of AgNCS because the Zn amalgam reduces not only Ag^+, but also NCS^-. $Ag_4Fe(CN)_6$ is only slightly reduced. $Ag_3Fe(CN)_6$ is reduced to $Ag_4Fe(CN)_6$ by reaction with the amalgam. For CuCl and CuI the reduction proceeded quantitatively and in CuNCS, NCS^- was reduced to H_2S. $HgCl_2$ and HgI_2 were reduced in several sec. with the Zn amalgam. Hg_2SO_4 was decompd. with difficulty, but quantitatively, while HgCl was only slightly decompd. K_2HgI_4 was reduced. Unsatisfactory results were obtained for CuS, while Ag_2S and HgS gave a quant reduction of the metals. Quant. decompn. of the sulfides of Pb, Cd, Bi, Sn and Sb was obtained. At temps. of 60–70° all the decompns. proceed more easily and rapidly. Five references. W. R. H. 1

The structures of boron hydrides. II. L. E. Agronomov. *J. Gen. Chem.* (U. S. S. R.) 9, 1389–93(1939); cf. *C. A.* 33, 6189[8].—The new exptl. results obtained by Schlesinger and Burg (*C. A.* 32, 2859[9]) for $B_2H_6.2NH_3$ (in their investigation of the reaction with Na in liquid ammonia) can be explained if the compd. is taken to be of the form $BH_3.NH_3$. The more complex formula (proposed by Schlesinger and Burg) $NH_4.[BH_3.NH_2.BH_3]^-$ is not based on exptl. results. The article gives also a possible scheme of the reaction for the formation of the compd. B_2H_7N that agrees with the formula $BH_3.NH_3$ for the ammoniate prepd. from diborane. Ten references. W. R. Henn 2

Recent developments in the chemistry of the boron hydrides. II. Some new reactions of diborane and its derivatives. A. J. E. Welch. *Chemistry & Industry* 1939, 937–40; cf. *C. A.* 34, 39[3]. R. F. D. 3

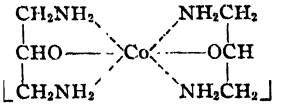
Some new halides of silicon. IV. A silicon chloride of formula SiCl. Robert Schwarz and Ulrich Gregor. *Z. anorg. allgem. Chem.* 241, 395–415(1939); cf. *C. A.* 32, 3716[6], 6169[8].—The method of formation, chem. behavior and constitution of SiCl were investigated; hydrolysis and ammonolysis gave new unsatd. Si compds. The thermal decompn. of $Si_{10}Cl_{20}H_2$ at normal pressure in inert atm. at 300° gave a solid, yellow SiCl or $(SiCl)_x$ of laminated, amorphous structure. Color change from yellow to orange-red is reversible between 180 and 200°, probably owing to the unsatd., highly polymeric character of the compd. SiCl is reduced in ammoniacal $AgNO_3$; Br_2 decomposes it into Si and unsatd. Si-Cl-Br compds. A very unstable compd. is formed with concd. HNO_3, which is explosively decomposed by contact or heating. SiCl does not react with dry O_2 in the cold; at 98° it burns briskly to fine SiO_2. Ammonolysis at room temp. gave $Si_6(NH_2)_6(NH)_3$ and $Si_8(NH_2)_8(NH)_2$. At temps. below 0° products of the same chain length were obtained. The results of ammonolysis of SiCl were confirmed by partial hydrolysis. Hydrolysis proceeds in three steps; at the second step chain members with 4-Si atoms appear. Results indicate that $(SiCl)_x$ is highly polymeric. M. McM. 4

Magnetochemical investigations. IV. Magnetochemistry of complex antimony compounds of various degrees of oxidation. R. W. Asmussen. *Z. Elektrochem.* 45, 698–703(1939).—Magnetic measurements were made in the systems $SbCl_3$–$SbCl_5$ and $SbCl_3$–Rb_2SbCl_6. One would expect Sb^{IV} to be *paramagnetic* and Sb^{III} and Sb^V to be *diamagnetic*. All the compds. in the systems studied were found to be diamagnetic. It is assumed that Sb has a valence which oscillates between 3 and 5, although this is in apparent disagreement with x-ray structure, which indicates that Sb is quadrivalent. H. Stoertz 5

The chemistry and morphology of the basic salts of bivalent metals. VII. Basic nickel chlorides. W. Feitknecht and A. Collet. *Helv. Chim. Acta* 22, 1428–44 (1939).—The chemistry of the solid solns. of Ni salts is discussed. In the pptn. of $NiCl_2$ with NaOH a basic dispersed chloride is obtained that gradually changes into the hydroxide. During this aging the pH decreases by about one unit. The soly. product is 1.1×10^{-16}. Expts. on the aging reaction at various concns. and temps. led to 5 basic chlorides of different structures. The following "ideal" formulas are suggested: (*a*) $1\,NiCl_2.Ni(OH)_2$; (*b*) $NiCl_2.3\,Ni(OH)_2$; (*c*) $NiCl_2.2Ni(OH)_2$; (*d*) $NiCl_2.3$–$4\,Ni(OH)_2.xH_2O$; (*e*) $NiCl_2.6$–$7Ni(OH)_2.xH_2O$. Their equil. conditions could not be investigated because reaction rates were too low. However, the greater part of them seem to be metastable. The respective crystallographic structures are discussed. **VIII. Basic nickel bromides.** *Ibid.* 1444–55.—Concd. solns. of $NiBr_2$ can contain much $Ni(OH)_2$. Six different basic Ni salts were obtained at varying temp. and concn. ranges. The following formulas are suggested: (*a*) $NiBr_2.3Ni(OH)_2$; (*b*) $NiBr_2.2Ni(OH)_2.4H_2O$; (*c*) $NiBr_2.7Ni(OH)_2.8H_2O$; (*d*) $NiBr_2.5Ni(OH)_2.8H_2O$; (*e*) $NiBr_2.5Ni(OH)_2.7H_2O$; (*f*) $NiBr_2.6$–$7Ni(OH)_2.xH_2O$. The compds. seem to be solid solns. No complex ions were found in the lattices. The lattice types are discussed. Robert Simha 6

Hydrothermal reactions. II. Magnesium hydrosilicate. 2. Wilhelm Jander and Reinhold Fett. *Z. anorg. allgem. Chem.* 242, 145–60(1939); cf. *C. A.* 32, 4898[8].—The synthesis of talc and serpentine was investigated at 600° and at 300°. A very simple phase diagram was derived. Between 100 and 60% MgO, $Mg(OH)_2$ + serpentine exists; between 60 and 42% MgO, serpentine + talc; with less MgO, talc + SiO_2. Anthophyllite and meerschaum were not found under exptl. conditions used. Fluorine seems to play an important role in the synthesis of chondrodite and humite. At least 6% F is necessary for the formation of chondrodite by hydrothermal reactions. At lower steam pressure the Mg orthosilicate, forsterite, is formed instead of serpentine. Temp.-pressure dependence of the formation of orthosilicate or serpentine is according to the equil.: $2(3MgO.2SiO_2.2H_2O) \rightleftarrows 3Mg_2SiO_4 + SiO_2 + 4H_2O$. This dependence is of great significance in the formation in nature. Corresponding equil. ratios were not observed with talc. They probably lie beyond the temp.-pressure region investigated. M. McMahon 7

Aluminum fluosilicate. Adrien A. Sanfourche and Alexandre Krapivine. *Bull. soc. chim.* 6, 1689–96(1939). —See *C. A.* 33, 6743[1]. J. F. D. 8



Mechanism of the formation of polythionic acids. II. Formation of polythionic acids with the aid of thiosulfurous acid. Hellmuth Stamm and Margot Goehring. *Z. anorg. allgem. Chem.* 242, 413–26(1939); cf. *C. A.* 33, 9178[8].—The following mechanism is proposed for the formation of polythionic acids in Wackenroder's soln. The starting point is the reaction between H_2S and SO_2 to form $H_2S_2O_2$, which reacts with more H_2S to form S and H_2O. $H_2S_2O_2$ then reacts with $2H_2SO_3$ to form $H_2S_4O_6 + 2H_2O$ and from these primary products all the other polythionic acids can be obtained as follows: $H_2S_4O_6 + H_2SO_3 \rightarrow H_2S_3O_6 + H_2S_2O_3$; $S + H_2SO_3 \rightleftarrows H_2S_2O_3$; $H_2S_4O_6 + H_2S \rightarrow S + 2H_2S_2O_3$; $H_2S_2O_2 + 2H_2S_2O_3 \rightarrow H_2S_6O_6 + 2H_2O$; $H_2S_6O_6 \rightarrow H_2S_5O_6 + S$. H. Stoertz 9

The hydrates of cobalt, nickel and copper sulfates. A. Simon and H. Knauer. *Z. anorg. allgem. Chem.* 242, 375–92(1939).—Dehydration of $CoSO_4.7H_2O$ in a desiccator over H_2SO_4 leads to a continuous loss of H_2O until the monohydrate is reached. Dehydration at a const. tension of 11 mm. indicates the existence of the hydrate $CoSO_4.6.5H_2O$, which is formed at 18°, after which the temp. steadily rises to 29.5° at which the hexahydrate, $CoSO_4.6H_2O$ is formed. $NiSO_4.7H_2O$ can be converted into tetragonal $NiSO_4.6H_2O$ by dehydration over H_2SO_4 in a desiccator. Crystd. from a concd. neutral soln., monoclinic hexahydrate is obtained. Treatment of the hexahydrates of Ni and Co and the pentahydrate of Cu with anhyd. liquid NH_3 indicates that 1 mol. of H_2O is bound in a manner different from the others. Ni and Co form the hexammine monohydrate and Cu the tetrammine monohydrate. Tensimetric decompn. of $NiSO_4.7H_2O$ at 11 mm. shows steps to correspond with $NiSO_4.6H_2O$ and $NiSO_4.4H_2O$. In dehydration of $CuSO_4.5H_2O$, if this is crystd. from H_2SO_4, a trihydrate is formed, which breaks down to monohydrate, but if the pentahydrate is obtained 10

from alc. soln. it goes directly to monohydrate. The results indicate the structure $[M(H_2O)_4][SO_4H_2O]$ for the Ni and Co salts and $[Cu(H_2O)_4][SO_4.H_2O]$ for the Cu salt. H. Stoertz

Active iron. XII. Magnetic character of a few complex iron salts. A Simon and H. Knauer. *Z. Elektrochem.* **45**, 678–85(1939).—In the salts (in which bip represents bipyridyl and phen represents phenanthroline) $[Fe(bip)_3]_2[PtCl_6]_3.0.7H_2O$, $[Fe(bip)_3]_2[PtCl_6]_3.3H_2O$, $[Fe(phen)_3]_2[PtCl_6]_3.1.4H_2O$, $[Fe(phen)_3]_3[PtCl_6]_3.1H_2O$, $[Fe(phen)]Cl_3$, magnetic susceptibility down to temps. of −190° follows Weiss's law rather closely. H. Stoertz

Coördination compounds of 1,3-diaminoisopropanol. J. G. Breckenridge and J. W. R. Hodgins. *Can. J. Research* **17, B**, 331–5(1939).—1,3-Diaminoisopropanol combines with cobaltous salts to give a series of *cobaltic coördination compds.* of the general formula $[(C_3H_9N_2O)_2Co]X$. The chloride, bromide, iodide, thiocyanate, nitrate, *d*-camphor-10-sulfonate, and *d*-α-bromocamphor-11-sulfonate were prepd. The last 2 were prepd. from the iodide by interaction with the Ag salt of the camphorsulfonic acid. These compds. were previously prepd. by the use of roseocobaltic salts. The complex cation is assigned the following structure

The base also gives cryst. coördination compds. with Cu^{++}, Ag and Zn salts. With Cu, the salts have the general formula $CuX_2.(C_3H_{10}N_2O)_2$, with $AgNO_3$ the salt $C_3H_{10}N_2O.AgNO_3.0.5H_2O$ was obtained, and with $ZnCl_2$ the cryst. product obtained did not correspond to any simple formula. H. Stoertz

The stereochemistry of complex inorganic compounds. VI. A study of the stereoisomers of the dichloro-diammino-ethylenediamine cobaltic ion. John C. Bailar, Jr., and Donald F. Peppard. *J. Am. Chem. Soc.* **62**, 105–9 (1940); cf. *C. A.* **34**, 3428.—The three isomeric forms of the dichloro-diammino-ethylenedianine cobaltic ion were prepd. The *cis*-dichloro-*cis*-diammino-ethylenediamine cobaltic ion is asymmetric and has not been resolved. It is most readily obtained through the reaction of *trans*-dichloro-*cis*-diammino-ethylenediamine cobaltic ion with Ag_2CO_3 to give carbonato-*cis*-diammino salt, which reacts with alc. HCl to give the *cis*-dichloro-*cis*-diammino isomer. The second step gives a mixt. of the cis and trans forms, owing to the rearrangement of the *cis*-dichloro form. The configurations of the two *cis*-dichloro forms were assigned through a study of the corresponding carbonato complexes. Improved methods are described for the prepn. of NH_4 *cis*-disulfito-tetrammino cobaltiate, NH_4 *cis*-disulfito-*trans*-diammino-ethylenediamine cobaltiate, cis and trans isomers of dichloro-*cis*-diammino-ethylenediamine cobaltic chloride, *trans*-dibromo-*cis*-diammino-ethylenediamine cobaltic bromide, and isomers of carbonato-*cis*-diammino-ethylenediamine cobaltic carbonate. A. B. Garrett

Constitution of complex metallic salts. X. Further evidence for the structure of bridged dipalladium derivatives. Joseph Ghatt and Frederick G. Mann. *J. Chem. Soc.* 1939, 1622–34; cf. *C. A.* **33**, 2434[3].—Previous conclusions of Mann and Purdie (*C. A.* **30**, 6668[8]) on the existence of the unsymmetric form in complex metallic salts are not supported by attempts to prep. a bridged compd. which could have only this structure. Two phosphine or arsine mols. were replaced by a suitable chelated mol. having two atoms united by coördinated links in the cis position to one Pd atom. Several unbridged Pd compds. contg. such chelated mols. were prepd., but none reacted further with $PdCl_2$ to give the required bridged derivs. The apparent nonexistence of such a bridged compd. is evidence against the existence of stable unsymmetric compds. The high value of the dipole moments of the bridged tetrachlorides and the dichloroöxalate cited by Mann and Purdie must be due primarily to the presence of a tautomeric mixt. of the cis and the trans symmetric forms alone. The yellow cryst. compd. $[C_2H_4(AsPhBu)_2PdCl_2]$, which contains two similar, asymmetric 4-covalent As atoms, was obtained in two forms, α m. 172–4°, β 185–6°; one of these forms must be the meso and the other the externally compensated isomer. This is the first recorded example of such isomerism in coördinated metallic derivatives. M. McMahon

Application of artificial radioelements to clearing up of a question of complex chemistry (Grinberg, Filinov) 3.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Chromatographic methods in inorganic chemistry. H. Erlenmeyer and H. Dahn. *Helv. Chim. Acta* **22**, 1369–71 (1939).—Schwab and his coworkers (cf. *C. A.* **31**, 8437[2], 3811[7], 6993[3]) have shown that chromatographic methods can be applied to the analysis of inorg. cations and anions. They used, for the most part, Al_2O_3 prepns. as adsorption agent and, when necessary, developed the colors of the different layers by the addn. of various reagents. Here, the use of 8-hydroxyquinoline(oxine) as adsorption agent in a tube 5–8 cm. long and 0.3 cm. in diam. is described. Schwab showed in his studies that the adsorption was probably due to the replacement of Na and the formation of metal aluminates. With oxine, hydroxyquinolates are formed. The order in which the adsorption takes place and the color of the layer formed are as follows: VO_3^- grayish black, WO_4^{--} yellow, Cu^{++} green, Bi^{+++} yellow, Ni^{++} green, Co^{++} pink, Zn^{++} yellow with intense green fluorescence, Fe^{+++} black, UO_2^{++} reddish orange. The order appears to correspond pretty well with the varying solubilities of the hydroxyquinolates but it also depends upon the pH of the liquid. Thus the order of Zn and Fe is reversed in AcOH solns. The sensitivity of the tests varies with the color formed. As little as 2 γ of Fe can be detected by the black zone formed. The method should find use in qual. or semiquant. tests. W. T. H.

Inorganic chromatography. IV. Chromatography as an auxiliary method in qualitative analysis. G. M. Schwab and A. N. Ghosh. *Angew. Chem.* **52**, 666–8 (1939); cf. *C. A.* **33**, 941[4].—The combination of the usual qual. analytical procedure and chromatography results in considerable improvements in the use of the latter, especially with the HCl, H_2S and $(NH_4)_2S$ groups. Karl Kammermeyer

Analytical results obtained by the explosion of gases. V. Beneš. *Chem. Obzor* **14**, 219–23(1939).—B. describes an app. in which gases are exploded completely or fractionally and analyzed for CO, H, CH_4, N, CO_2 and O. Results obtained in the analysis of generator gas are compared with those obtained by the usual combustion method. Frank Maresh

Spectral determination of elements in the spark by direct photoelectric measurement of line intensities. G. Thanheiser and J. Heyes. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* **21**, 327–34(1939).—The efforts to det. spectral lines in the spark instead of in the flame because of greater intensity of the lines in the spark and better possibility of detn. in the ultraviolet range are described and the shortcomings discussed. A direct photoelec. detn. is described in which the light emanating from the spark is divided in two parts by a prism system and each part examd. spectrally. One line of each part spectrum is prepd. by a monochromator and the intensity of this line caused to act on a photocell and the photocurrents are measured by the charging of two electrometers. The

quotients of the two charges in a given time are proportional to the ratio of the line intensities and permit detn. of the element if the relation between line intensity and concn. of the element is known. App. and procedure are described in full. The av. error of the measurement is 1.49%. An example of the detn. of Mn and Mg in Al illustrates the method which proved to have the same accuracy as detn. with the photographic plate.
M. Hartenheim

Organic reagents in inorganic analysis. J. Albert Southern. *Furman Bull.* **22**, 14–23(1940).—A review with 61 references. W. T. H.

Use of base-exchanging substances in analytical chemistry. II. Olof Samuelson. *Svensk. Kem. Tid.* **51**, 195–206(1939)(in German); cf. *C. A.* **33**, 5767[1].—Burrell, *C. A.* **32**, 4700[8], has proposed the name *organolite* for org. substances which behave like permutite and other zeolites for removing cations from aq. solns. In the expts. here described the organolite used was a sulfonic acid. With the aid of 3.2 g. of the organolite it was possible to remove all Al^{+++} from a soln. contg. a little more than 2 milliequiv. of $Al_2(SO_4)_3$ and H^+ ions replaced the Al^{+++} in the soln. The H^+ equiv. to the SO_4^{--} could then be titrated with NaOH to a methyl red end point. In 30 expts. most of the values were excellent although there was nearly 1% error in a few cases. The organolite could be regenerated by washing with 200 ml. of 2 *N* HCl followed by pure water. The analysis required much less time than the usual methods. With about 5 g. of organolite which was satd. with NH_4^+ ions it was possible completely to remove a little over 2 milliequiv. of K^+ and the anions were left in the filtrate. Then, by washing with HCl, all the absorbed alkali cations could be removed and, after evapn. to dryness and careful ignition, the Cl^- equiv. to the K^+ could be titrated with $AgNO_3$. Such a method of analysis is particularly advantageous when a nonvolatile anion such as VO_3^- is present. Much less time is required than when the VO_3^- is removed by means of the insol. Pb salt and the results appear to be better. Bibliography of 15 titles.

Determination of arsenic by the distillation method. D. R. Jackson. *J. S. African Chem. Inst.* **22**, 68–70 (1939).—Loss of $AsCl_3$ on mixing the H_2SO_4 soln. with HCl can be avoided by pptg. the As as As_2S_3 and using this ppt. in the distn. with HCl. A. B. Garrett

The microestimation of arsenic. P. Kamerman. *J. S. African Chem. Inst.* **22**, 63–7(1939).—To carry out the Gutzeit test, it is recommended to bubble the AsH_3 through $AgNO_3$ soln. contg. gum arabic to protect the Ag sol formed and to measure the color in a Lovibond Tintometer. The method is suitable for detg. 2–20 γ of As.
A. B. Garrett

Determination of extremely small quantities of iron in aluminum by means of photoelectric colorimetry. M. Kofler and H. v. Halban. *Helv. Chim. Acta* **22**, 1395–1403(1939).—The Fe content can be detd. within 10% of the truth when 0.05–2.0% of Fe is present provided there are available test electrodes of accurately known compn. The photoelec. method is capable of detecting very much less than 0.0001% of Fe in metallic Al. Contents of 0.0001–0.01% were studied and results obtained which were within 10% of the truth after 10 g. of metal was dissolved in HCl and the soln. dild. to one l. Particular attention was paid to the Fe content of the acid used. W. T. H.

Rapid method of estimating small amounts of iron and manganese in copper-nickel-zinc alloys. Harendra Nath Roy. *J. Indian Chem. Soc.* **16**, 419–20(1939).—The alloy is dissolved in dil. HNO_3 and the Fe + Mn are pptd. as $Fe(OH)_3$ and H_2MnO_2 by means of NH_4OH and Br_2. The well-washed ppt. is dissolved in H_2SO_4 + $NaHSO_3$ and is oxidized by persulfate. After boiling to decomp. the excess persulfate, the acid soln. is reduced in a Jones' reductor and the Fe^{++} titrated with 0.02 *N* $KMnO_4$. After this the Mn is detd. by the persulfate method.
W. T. H.

Estimation of lithium as lithium potassium ferric periodate. O. Pročke and A. Šlouf. *Collection Czech Chem. Commun.* **11**, 273–94(1939).—P. and Uzel, *C. A.* **32**, 5329[9], showed that Li can be pptd. as $LiKFeIO_6$. In this paper the best conditions for carrying out the quant. pptn. were detd. and the best way to det. Li in the presence of Na. To carry out the analysis, evap. the soln. contg. the chlorides or sulfates of Na and Li to about 1 ml. In the tests, the Li content varied from 0.07 to 3.5 mg. To remove the Na, treat the soln. with EtOH which has been satd. with HCl. Remove the NaCl and wash the ppt. 3 times with 2-ml. portions of the alc. soln. of HCl. Evap. the filtrate contg. the Li to about 1 ml. and make about 1.0 *N* in KOH. While stirring and heating to 90° slowly add the reagent. It is prepd. from 2.3 g. of KIO_4, 10 ml. of 2 *N* KOH, 2 ml. of *N* $FeCl_3$ soln., 40 ml. of 2 *N* KOH and water to make 100 ml. When all the Li has been pptd. and the supernatant liquid is clear, filter and wash the ppt. of $LiKFeIO_6$ with 0.25 *N* KOH soln. Dissolve the washed ppt. in dil. H_2SO_4, add KOH till neutral and then just enough acid to clear the soln. Add an excess of KI and after some time add $NaHCO_3$ and titrate the liberated I_2 with standard arsenite or thiosulfate soln. Seven equivs. of I_2 correspond to 1 atom of Li.
W. T. H.

Colorimetric determination of manganese in the presence of organic substances and of Cu, Al, Zn, Ca, Mg, Fe and P, with special reference to drug preparations. Elemér Schulek and Pál Menyhárth. *Magyar Gyógyszerésztud. Társaság Értesítője* **15**, 513–20(1939).—Take sufficient sample to furnish 0.1–1.0 mg. of Mn. Digest it with concd. H_2SO_4, fuming and cautiously adding small portions of H_2O_2 until all org. matter is destroyed. Cool, dil. and oxidize the Mn to MnO_4^- by persulfate in the presence of Ag^+. Det. the color photometrically. Full details are given for carrying out the analysis. If much Fe is present, the addn. of H_3PO_4 is advisable and in some cases filtration is necessary before adding the presulfate.
S. S. de Finály

Method for determining very small quantities of molybdenum, applicable to biological material. Didier Bertrand. *Bull. soc. chim.* **6**, 1676–89(1939).—ter Meulen (*C. A.* **25**, 3882) studied the detn. of Mo in vegetable products but used samples weighing 3–5 kg. His method of basing the detn. upon the color of colloidal MoS_3 can serve to detect in 5 ml. of soln. as little as 0.2 mg. Mo per l. Sb, Sn and Sn cause interference. A procedure is given here for starting with 100 g. of material and detg. as little as 2 γ of Mo. With 14–15 g. of ash as little as 1–2 γ of Mo can be detd. Special pains should be taken during the calcination of the sample. Then, on treating the ash with HCl and removing the Si, it is necessary to remember that some Mo is contained in the insol. residue and it can be recovered by fusion with $NaHCO_3$. The sulfide test does not work well if much salt is present and it is convenient to conc. the Mo by forming a complex with cupferron and extg. it with $CHCl_3$. To remove the Sn, careful neutralization with NH_4OH succeeds provided a little Fe^{+++} is present. Cu is removed by pptn. with Na_2S. The final detn. of Mo is made with the aid of a photoelec. cell in a vol. of less than 9 ml. Full details are given for carrying out the entire procedure. W. T. H.

Amperometric titrations. II. The titration of nickel with dimethylglyoxime using the dropping-mercury electrode as indicator electrode. I. M. Kolthoff and A. Langer. *J. Am. Chem. Soc.* **62**, 211–18(1940); cf. *C. A.* **34**, 958[6].—This method yields accurate and precise results for very dil. Ni solns., good results being obtained in a concn. range between 0.01 and 0.0001 *M*. The interference by other metal ions is discussed. Procedures are described for the detn. of Ni after removal of large amts. of Co and of Fe. The procedure given for the detn. of Ni in Ni steel yields good results. A. B. Garrett

Determination of tantalum and columbium in ferrotantalum, ferrocolumbium and ferrotantalocolumbium. K. Brüning, K. Meier and H. Wirtz. *Metall u. Erz* **36**, 551–4(1939).—To det. the sum of the oxides Ta_2O_5 + Cb_2O_5, place 1 to 2 g. of alloy in H_2O in a covered Pt dish, add 3 to 4 ml. HNO_3 and if necessary small amts. of HF until soln. is complete. Add 10 ml. of 12 *N* H_2SO_4 and heat the mixt. to fumes. Fuse the salts so obtained with KH-

SO_4 until the melt is bright red in color. Ext. it with H_2O, dil. to about 800 ml., and digest for 0.5 hr. with SO_2, which completely separates Ta and Cb. Filter the ppt. and wash with H_2O contg. SO_2; all the Ta and Cb, nearly all the Sn, most of the Ti and a small amt. of Fe remain on the filter. Carefully wash the ppt. into an 800-ml. beaker with hot H_2O, and add 100 ml. of 6 *N* HCl and 25 ml. of perhydrol. Heat the soln. until clear, dil. to 500 ml. and digest for 20 min. Filter the ppt., wash with hot H_2O, redissolve as above and reppt. The ppt. is now free of impurities, but some of the Ta and Cb are in soln. To recover these, evap. the filtrates to about 500 ml., and add NH_4OH until the soln. will contain only about 30 to 40 ml. of 6 *N* HCl. Heat to 90° and allow to stand 12 hrs. If a ppt. forms, filter, and wash the ppt. with H_2O contg. HCl. Heat the filtrate to 40 to 50°, and sat. with H_2S, after which filter the ppt. and wash with H_2O contg. NH_4NO_3. This ppt. is free of Ta and Cb. In the H_2S-contg. filtrate, which is boiled, ppt. Ta, Cb and Ti with NH_4OH, filter, ash in a porcelain crucible and fuse with $KHSO_4$. Take up the melt with H_2O, add 30 ml. of 12 *N* HCl, dil. to 300 ml. with H_2O and neutralize with NH_4OH. Again add 30 ml. of 12 *N* HCl, dil. the soln. to 500 ml. and digest for 20 min. The remainder of the Ta and Cb sep., leaving Ti in soln. Filter the ppt. and wash with H_2O contg. HCl. Combine the 3 ppts. and ash in a porcelain crucible to Ta_2O_5 and Cb_2O_5. Sep. the Ta and Cb by a crystn. method based on the work of Marignac. H. Stoertz

Rapid method for determining halogen in gaseous mixtures containing chlorine and fluorine substitution products of hydrocarbons. W. D. Treadwell and M. Zürcher. *Helv. Chim. Acta* **22**, 1371–80(1939).—The use of CF_2Cl_2 has become quite common in refrigeration. The tech. testing is usually based upon the detn. of the d. and the halogen content of a given vol. of gas. The method here proposed consists in mixing a known quantity of sample with a large excess of H_2 and a little air, burning the mixt. from a narrow Pt capillary, condensing the water and analyzing the condensate for HF and HCl. The mixt. suitable for analysis can be obtained by passing H_2 through the liquid. For condensing all the HF and HCl with the H_2O it was found necessary to introduce a little excess water vapor. Sufficient air is provided so that the products of the combustion are CO_2, H_2O, HF and HCl together with a very little Cl_2. From 25 ml. of the sample, about 25 ml. of aq. soln. was obtained which was approx. 0.1 *N* in HCl and 0.1 *N* in HF. The Cl^- can be titrated in an aliquot part of the condensate with $AgNO_3$ and in another part of the condensate the F^- can be titrated with $FeCl_3$ if the aq. soln. is satd. with NaCl and the titration done in an atm. of CO_2. Both end points can be detd. electrometrically. Known wts. of CF_2Cl_2, $CHCl_3$, C_6H_5Cl and CCl_4 were analyzed. From samples contg. 1.5, 26.0 and 106.4 mg. of Cl, the values 1.2, 25.4 and 104.9 mg. Cl were obtained and from samples contg. 13.7 and 14.8 mg. F the values 13.2 and 14.6 mg. F were obtained. Three different methods for carrying out the condensation are described. In one case the H_2 mixt. is burned in a cake of ice obtained from about 1 kg. of distd. water. In the second case a water-cooled condenser is used and in the third case, the combustion takes place in a glass vessel kept at const. temp.; the gases formed are removed by suction and the condensation of the HCl and HF is effected in an efficient wash bottle contg. dil. alkali hydroxide. W. T. H.

A method for a rapid and accurate determination of small concentrations of chlorine in air. A. N. Mal'chevskiĭ. *Hig. i Sanitariya* **1938**, No. 11–12, 37–43; *Khim. Referat. Zhur.* **2**, No. 4, 74–5(1939).—A construction of an absorbing app. is proposed and a method for the detn. of Cl in air is given. The air under investigation is drawn through a soln. contg. KI, starch and a standardized soln. of As_2O_3 or $Na_2S_2O_3$. The amt. of Cl is detd. from the vol. of air which it is necessary to pass through the absorber to give a blue color to the starch. The absorber consists of a test tube 17 cm. long and 1.8 cm. in diam. A glass rod is sealed to the enlarged upper part of the test tube for the passing of gas. The surface of the test tube has deformities for better mixing of air. The absorber is closed with a stopper through which a sealed tube for air is passed almost to the bottom. The end of this tube has a 0.1–0.2-mm. opening. The vol. of the absorbing soln. is 15–17 cc. At a Cl concn. of 5–50 mg. per cu. mm. the air is passed with a velocity of 0.5–0.7 l./min. The error is about 5%. The time of one detn. is 4–6 min. W. R. Henn

Phosphorus determination in vanadium slags. E. Stengel. *Arch. Eisenhüttenw.* **13**, 205–7(1939).—See *C. A.* **33**, 9192⁴. Max Hartenheim

Scattered elements in salt deposits. Yu. V. Morachevskiĭ and T. V. Polenova. *Byull. Inst. Halurgii* **1938**, No. 3, 1–12; *Khim. Referat. Zhur.* **2**, No. 4, 76(1939).—For very small amts. of admixts. in salts methods of prepn. of analytical concentrate and the direct detn. of elements in this concentrate are proposed. For elements of analytical groups III and IV dissolve the sample of salt (7–10 kg.) in hot distd. water in a 35–40-l. porcelain container heated by elec. coils, collect the insol. residue in a large Büchner funnel and wash with hot water. Acidify the filtrate with HCl (20 cc. of concd. HCl per l. of soln.), heat to 70–80°, introduce H_2S gas, after 1.5 hrs. add 0.1 g. of $HgCl_2$ dissolved in a little water, introduce H_2S gas for 2–3 hrs. more with frequent shaking and let stand overnight. Filter off the ppt. of the sulfides through a Büchner funnel, wash with water satd. with H_2S, dry the residue at 50–60° and save it for further analysis. After the sepn. of groups IV and V, make the filtrate slightly alk. with NH_4OH and pass H_2S gas through the soln. Let stand overnight, filter off the ppt., wash with water contg. $(NH_4)_2S$ and dry as previously. Analyze the ppts. by the usual methods. Sep. the Hg residue from Hg by roasting at 600°, treat the residue with HNO_3, filter off the insol. part, roast, remove SiO_2 with HF and H_2SO_4, fuse with $K_2S_2O_7$, combine the soln. of the melt with the main soln. and det. Pb and Cu. Transfer the sulfide residue of the elements of group III to a HCl soln., remove SiO_2 from the insol. part (as explained above) and det. Fe, Ni, Mn and Zn in the soln. Fourteen samples of salts from the Solikamsk deposits were analyzed according to the method described. The amts. of the elements found were from 10^{-6} to 10^{-4}%. W. R. Henn

The microestimation of sulfates in sea water and the body fluids of marine animals. D. A. Webb. *J. Exptl. Biol.* **16**, 438–45(1939).—The basic principle of the method is the addn. of an insol. iodate which reacts with the ion to be estd. so as to form a more insol. salt and liberate iodate ions into the soln. For the estn. of chloride $AgIO_3$ is used; for sulfate, $Ba(IO_3)_2$. The IO_3^- ion is then detd. iodometrically. Benjamin Prescott

Determinations by means of sulfocarbamide. II. The titrimetric determination of manganese dioxide, lead dioxide and per-compounds. C. Mahr and Hertha Ohle. *Angew. Chem.* **52**, 618(1939); cf. *C. A.* **33**, 4549⁴.—Oxidizing reagents can be detd. by the addn. of excess sulfocarbamide and titration of the excess with bromate-bromide soln. Exptl. results are shown for MnO_2, PbO_2, $K_2S_2O_8$ and H_2O_2. 5 references. K. Kammermeyer

Determination of carbon dioxide in aqueous solution. J. R. I. Hepburn. *J. Soc. Chem. Ind.* **58**, 340–2(1939).—The method serves to det. quickly and accurately both free and combined CO_2. Possible applications are the detn. of CO_2 in *spring waters, baking powders, self-rising flours* and for the analysis of carbonates which are not decompd. readily by mineral acid at room temp. The CO_2 is liberated in an app. under reduced pressure, absorbed in a measured vol. of 0.1 *N* $Ba(OH)_2$ and finally the excess is back titrated with oxalic acid. W. T. H.

Hydrogen peroxide determination. P. Thorsell and E. Bengtsson. *Svensk Farm. Tid.* **43**, 567–70(1939).—The usual nitric acid NH_4 molybdate reagent may replace neutral $(NH_4)_2MoO_4$ soln. in reducing the time for detg. H_2O_2 by adding KI and titrating the liberated I with 0.1 *N* $Na_2S_2O_3$. A. R. Rose

Revised procedure for the qualitative analysis of Group III cations. Wm. J. Tomsicek and James J. Carney. *J. Chem. Education* **17**, 29–31(1940).—Kolthoff, Stenger and Moskovitz (*C. A.* **28**, 3024[8]) showed that a buffered soln. of benzoic acid was better for sepg. Fe, Al and Cr from Ni, Co, Mn and Zn than most other methods. In this paper a complete scheme for the analysis of Group III is given and the results of several hundred analyses by students indicate that the procedure is suitable for beginners. No particular attention is paid to the possible presence of anions such as PO_4^{---}, F^- and $C_2O_4^{--}$. The soln. is neutralized, made slightly acidic with AcOH and boiled after adding NH_4Cl and NH_4 benzoate. The resulting ppt. is analyzed for Fe, Cr and Al in the conventional way. In the filtrate, Mn, Ni, Co and Zn are first pptd. as sulfides and in the filtrate tests are made for Groups IV and V. The sulfide ppt. is dissolved in hot HNO_3 and the Mn pptd. as MnO_2 by boiling with HNO_3 + $KClO_3$. In the filtrate from the MnO_2 pptn. Ni and Co are pptd. as hydroxides and thus sepd. from Zn by means of excess NaOH. The Zn is finally identified by the sulfide pptn. and as the 8-hydroxyquinolate. Ni is eventually identified by the pptn. with dimethylglyoxime and Co is identified by Vogel's test. W. T. H.

Gas determination in aluminum. E. Schmid and H. D. Graf v. Schweinitz. *Aluminium* **21**, 772–8(1939).—When the H_2 dissolved in Al was detd. quite considerable differences were obtained, depending on whether the detn. was made by hot-extn. with or without cold deformation, detn. of equil., bombardment with ions, or chemically. Special expts. were made with pure Al which showed that the reason for the error in the results is H_2 originating from surface reactions between metal and adsorbed water with formation of Al_2O_3 and H_2. This addnl. H_2 is the greater the larger the ratio of surface to vol. This was the case also in the two most accurate methods, viz., elec. bombardment and hot-extn., which both gave in spite of very large differences in the dimensions of specimens, practically the same amts. of H_2 for specimens of the same dimension. If a specimen is exposed to air after a detn. H_2 is found again, also after cold deformation. But while cold deformation does not influence the result of the detn. very much, exposure to air does so very much more; the effect of cold deformation is due only to enlarged surface, which again adsorbs more humidity. Systematic characterization of atomic groups (in organic compounds) with respect to analytical chemistry. J. V. Dubsky. *Collection Czech Chem. Commun.* **11**, 295–312 (1939); cf. *C. A.* **31**, 7785[6]; **32**, 74[6], 4472[5].—A lecture read at Delft on May 25, 1939 in which the relations between the structure of the mol. of an org. reagent and the ability to form characteristic color tests with various cations are pointed out. W. T. H.

Identification of the halogen in organic halogen compounds. David W. Wilson and Cecil L. Wilson. *J. Chem. Soc.* **1939**, 1956–8(1940).—The microchem. procedure here described is based upon the fact that AgI, AgBr and AgCl formed under suitable conditions can be distinguished from one another under the microscope. The predominant forms of AgCl are octahedra, cubes and squares but AgBr forms triangular and hexagonal plates. AgI is easily sepd. from AgCl and AgBr by means of NH_4OH but the insol. AgI can be dissolved in pyridine from which it crystallizes in characteristic, transparent, oblong shapes which are easily recognized if the specimen is not allowed to become dry. There is no difficulty in identifying the iodide and the chloride or bromide is easy to recognize when it is fairly pure. When both chloride and bromide are present, considerable care is necessary in accomplishing satisfactory sepn. by means of dil. NH_4OH. As little as 1 γ of either Cl, Br or I can be recognized. One part of Cl in the presence of 10 of Br or one of Br in the presence of 30 of Cl can be detected and 1 part of I in the presence of 50 parts of either of the others is detectable. A pos. test for Cl can be obtained when no ppt. is visible to the naked eye. W. T. H.

Methods of determining formaldehyde. A. Foschini and M. Talenti. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., **1939**, 54–60; cf. *C. A.* **33**, 7238[3].—A review. L. E. Gilson

Analytical procedures employing the Karl Fisher reagent. II. The determination of alcoholic hydroxyl. W. M. D. Bryant, J. Mitchell, Jr., and Donald Milton Smith. *J. Am. Chem. Soc.* **62**, 1–3(1940); cf. *C. A.* **33**, 8524[3].—The analysis depends upon the general reaction $ROH + CH_3COOH = CH_3COOR + H_2O$. By employing a large excess of AcOH and making use of BF_3 as an esterification catalyst it is possible to shift the equil. almost completely to the right. The H_2O content is then detd. by direct titration with the Karl Fisher reagent (cf. *C. A.* **33**, 8524[3]). This new hydroxyl procedure is applicable to aliphatic and alicyclic alcs. including branched-chain types and hydroxyl acids, also such aromatic alcs. as have the hydroxyl group attached to an aliphatic side chain. Phenols do not react completely. Aldehydes, ketones, acetals, ketals and amines affect the procedure unfavorably. Differences in the relative esterification rates of aliphatic and strictly aromatic alcs. make it possible to differentiate these 2 classes of compds. by this method. **III. The determination of organic acids.** J. Mitchell, Jr., Donald Milton Smith and W. M. D. Bryant. *Ibid.* 4–6.—The basis of this procedure is the estn. of water liberated by the reaction $RCOOH + CH_3OH \rightarrow RCOOCH_3 + H_2O$ catalyzed with BF_3. The procedure is applicable to aliphatic acids generally, including branched-chain and hydroxyl-substituted types, and also aromatic acids having the carboxyl attached to an aliphatic side chain. Typical aromatic acids having the carboxyl group attached directly to the ring do not react quantitatively. Boric acid, anhydrides and strong inorg. acids may interfere. A. B. Garrett

The determination of organic peroxides. Herman A. Liebhafsky and Wm. H. Sharkey. *J. Am. Chem. Soc.* **62**, 190–2(1940).—Iodometric methods for the analysis of peroxides were modified to meet the following requirements: (1) a reaction system homogeneous even during the titration; (2) a negligible blank; (3) liberation of I_2 complete within 10 min.; (4) accuracy to within 2 drops of 0.01 *N* soln. Homogeneity and rapid I_2 liberation are obtained in glacial AcOH. The addn. of $NaHCO_3$ to the reaction mixt. eliminates the necessity of a blank. KI soln. is added to the mixt. contg. AcOH, $NaHCO_3$ and the peroxide; the mixt. is then titrated with 0.01 *N* thiosulfate. Several observations are made concerning the reaction rates. A. B. Garrett

Behavior of diethylmalonylurea and certain pyrazolone derivatives with various reagents. Antonio Perotti. *Boll. chim. farm.* **78**, 497–505(1939).—A study of the behavior of Millon's reagent; Dénige's reagent; a mixt. of 1 g. $CO(NO_3)_3$, 1 g. $CaCl_2$ in 10 cc. H_2O; 5% vanillin in alc. in the presence of H_2SO_4; and of a mixt. of 10% $CO(NO_3)_3$, 10% KCN in the presence of 10% NH_4OH on barbital (I), antipyrine (II), pyramidone (III), mixts. of 1 mol. I and 1 mol. II; 1 mol. I and 2 mols. II; 1 mol. I and 1 mol. III; 1 mol. I and 2 mols. III; 1 mol. I, 1 mol. II and 2 mols. III; and Antinevralgico "Alpha" (IV). Mixts. of I and II gave no reactions characteristic of I whereas mixts. of I and III indicated the existence of free I. The behavior of IV suggested the formation of a complex between I, II and III and this finding was confirmed by photomicrographs of the cryst. products. C. R. A.

Determination of tartaric acid by oxidation with silver salt. A. N. Smolin. *Uchenye Zapiski Fakul'teta Estestvoznaniya Moskov. Gosudarst. Pedagogicheskogo Inst. (Lab. Org. i Biol. Khim.)* **1938**, No. 3, 189–93; *Khim. Referat. Zhur.* 2, No. 4, 79(1939).—The method is based upon the fact that tartaric acid reduces an ammoniacal soln. of silver nitrate; the reduced Ag is dissolved and detd. by the Volhard method of titrating with alkali thiocyanate. To 10 cc. of the soln. contg. about 75 mg. tartaric acid, add an excess $AgNO_3$, 1.3–1.5 cc. of a concd. NH_4OH and an excess of alkali hydroxide. Carry out a

control expt. in which the vol. of the tartaric acid soln. is replaced by an equal amt. of water. Heat the soln. for 2 hrs. at 50–60°, cool, add 0.5–1 cc. of NH_4OH soln., mix and dil. to a known vol. Filter, and dissolve the Ag residue in dil. HNO_3 and titrate with KCNS soln. by the method of Volhard. The method can be used for the detn. of tartaric acid in the presence of citric, malic, oxalic and succinic acids and is as accurate as the detn. based on the low soly. of $KHC_4H_4O_6$. W. R. Henn 1

Determination of aromatic aldehydes. A. Eitel and G. Lock. *Monatsh.* **72**, 385–91; *Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIb, **148**, 83–9(1939).—A modification of the method of Houghton (*C. A.* **28**, 2641[2]) is used. The reagent is prepd. from 2.5 g. 2,4-$(O_2N)_2C_6H_3$-$NHNH_2$ and 50 cc. concd. H_2SO_4 in 950 cc. H_2O; 100 cc. of this reagent is used per millimole of aldehyde. Use of BzH (0.9852 g.) in 100 cc. acid-free EtOH (99.28% of BzH present), 5 cc. of the soln. and 50 cc. of the reagent, dild. to 200 cc. with H_2O, stirred a few min. and allowed to stand overnight, give 98.72–99.24% of BzH as the hydrazone, m. 238°; with dioxane as the solvent, the yield of hydrazone varies from 98.88 to 99.15%. Similar results were obtained with the 3 ClC_6H_4CHO. *m-Chlorobenzaldehyde 2,4-dinitrophenylhydrazone*, Bordeaux-red, m. 248°; *p-isomer*, light brown, m. 264° (m. ps. cor.). C. J. West 2

The determination and identification of phenolic compounds in very dilute solution by means of an improved indophenol reaction. L. F. Levy. *J. S. African Chem. Inst.* **22**, 29–36(1939).—The principle underlying the Houghton and Pelly (cf. *C. A.* **31**, 3184[4]) method was adopted: the pH of the phenol soln. was adjusted to 9.2–10.5, a little of 2,6-dibromo-4-aminophenol was added, mixed and then 2 mols. of 0.05% NaOCl soln. added for each mol. of the reagent. The indophenol color developed in 3–5 min. It was found that an aq. or alc. soln. of 2,6-dibromo-4 aminophenol chlorostannate, on addn. to the buffered soln., produces a colorless soln. which lends itself perfectly to the estn. of the phenols in such solns. The phenols are identified by the blue color of the indophenols which are stable in AcOH soln. buffered to pH = 3–4. A. B. Garrett 3

(Izmailov, Tkachenko) **10**.

pH Determinations. Solomon F. Acree. U. S. 2,178,550, Nov. 7. Various details of pH determinations and buffers and indicators for such use are described, including a process of preparing a series of indicators standardized as to pH and chosen concn. without added buffers. The process consists in adding to chosen concns. of the indicators having useful colorimetric pH ranges between pH 0 and pH 14 the requisite amts. of standard alkali or acid and making comparisons thereof in thin layers by Beer's law against pH color standards to form a series of indicator standards varying from pH 0 to pH 14 by definite predetd. small increments. The CO_2 content of a sterile buffer standard is adjusted to equil. with the CO_2 of the atm. and Na acid orthophthalate may be used. 4

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

X-rays in mineralogy. Design of a serviceable apparatus. M. A. Peacock. *Univ. Toronto Studies, Geol. Ser.* No. 42, 79–93(1939).—In the study of minerals older methods do not suffice for their identification, e. g., chem. analysis, crystal habits, etc. Since the x-rays have been applied to the study of minerals many which previously could not be classified or were difficult to classify can be grouped with their resp. kind. The x-ray has made possible measurements of the distance between the several planes of atoms; hence by calcn. the size of the unit cell becomes known. H. E. Messmore 6

Fungi as destructive and constructive agents of minerals and rocks. František Ulrich. *Věda Přírodní* **19**, 45–50 (1938); *Mineralog. Abstracts* **7**, 408.—The lublinite variety of calcite occurring in cretaceous rocks of N. Bohemia and W. Moravia is frequently of biogenetic origin, the fibers of various hyphomycetes detg. the crystn. and structure of the $CaCO_3$. C. A. Silberrad 7

Greenockite from Llallagua, Bolivia. Samuel G. Gordon. *Notulae Naturae, Acad. Natural Sci. Phila.* No. 1, 1–6(1939).—The greenockite from the Sn mines of Llallagua is remarkable for its red color and cyclic twinned crystals. Results of spectroscopic and microchem. tests show the mineral to consist essentialy of Cd, Fe and S, with traces of Zn, Si and Al (the Fe being probably due to admixed pyrite or marcasite, the greenockite occurring usually on marcasite). The crystals vary in habit, being pyramidal, thick tubular or prismatic. Crystals twinned on $i(10\bar{1}2)$ are common, being simple contact twins of 2 individuals or cyclic twins with 4 individuals in 4 equiv. positions. Crystallographic measurements (given) identify the crystals with forms already recorded for greenockite. Drawings and one photomicrograph are included. A note on twinned wurtzite from Frisco, Utah is also given. Microchem. tests show the mineral to be ZnS, and the twins examd. are similar to those in greenockite. Edward B. Sanigar 8

Nickeliferous pyrite from the Denison Mine, Sudbury District, Ontario. Ellis Thomson and J. S. Allen. *Univ. Toronto Studies, Geol. Ser.* No. 42, 135–9(1939).—Nickeliferous pyrite from the Denison Mine was of a faint violet shade modifying the usual color of pyrite. Several types were observed, one creamy in color, one of the above-mentioned violet, and the third was intermediate between these. The sp. gr. was approx. 4.81 and the Ni content amounted to approx. $^1/_2$ atom per unit cell of Fe_4S_8, the Ni replacing the Fe. This mineral has essentially the chem. and structural properties of pyrite. H. E. Messmore 9

Mineral of domeykite group from Běloves near Náchod (Bohemia). Ladislav Janota and S. Kraus. *Věda Přírodní* **19**, 152(1938); *Mineralog. Abstracts* **7**, 409.—The mineral is silver-gray and metallic, and contains 73.21% Cu with As. It is disseminated in cuprite. Besides cuprite, olivenite and tyrolite occur in this neighborhood. C. A. Silberrad 10

Studies of mineral sulfo-salts. I. Cosalite from Canada and Sweden. L. G. Berry. *Univ. Toronto Studies, Geol. Ser.* No. 42, 23–31(1939).—Cosalite from McElroy Township, Timiskaming district, Ontario, for which a reliable analysis and d. measurement were available, is orthorhombic; space group $D_{2h}^{16} = Pbnm$ or $C_{2v}^{9} = Pbn$. The unit cell, $a_0 = 19.05 \pm 0.03$, $b_0 = 23.82 \pm 0.03$, $c_0 = 4.047 \pm 0.01$ A., contains $8[(Pb,Cu)_2Bi_2S_5]$. Cosalite from the Cariboo Gold Quartz Mine, and the Island Mountain Mine, Cariboo district, British Columbia, and from Nordmark, Sweden, give powder photographs identical with that on the Ontario material. H. E. Messmore 11

Occurrence of cosalite in British Columbia. H. V. Warren. *Univ. Toronto Studies, Geol. Ser.* No. 42, 151–5 (1939).—Certain ore shoots at the Cariboo Gold Quartz Mine contain the rare minerals cosalite and galenobismutite, closely assocd. with native Au. These minerals were deposited at approx. the same time. Some ankerite was found as an uncommon gang mineral. Galena, sphalerite and chalcopyrite also occur in minor quantities. The cosalite contains approx. 41.2 Pb, 39.3 Bi, 16.0 ± 0.3 S, 0–3.6 Cu and 0–1.8% insol. The formula should be Pb_2- 12

Bi_2S_3. The cosalite contains 0.15–10.10% free Au. H. E. Messmore

Rammelsbergite from Ontario. M. A. Peacock and C. E. Michener. *Univ. Toronto Studies, Geol. Ser.* No. 42, 95–112(1939).—The mineral occurred with maucherite and temiskamite, at Moose Horn Mine, Elk Lake, Ontario. It is white in color; with crystals approx. 0.06 mm. in diam. The mineral is anisotropic, gives polarization colors and consists of 27–28% Ni, 66–68% As, and usually 2–3% S. Occasionally 1–2% Co is present, with traces of impurities. This particular sample was described as pseudo-orthorhombic, with cell edges of $a_0 = 5.74$, $b_0 = 5.81$ and $c_0 = 11.405$ A., the cell const. Ni_8As_{12}. H. E. Messmore

Magnesiochromite from Caribou pit Coleraine Township, Quebec. A. L. Parsons. *Univ. Toronto Studies, Geol. Ser.* No. 42, 75–8(1939).—A sample of magnesiochromite for analysis and x-ray examn. was sepd. from impurities by use of Clerici's soln., and a magnetic separator. The chem. analysis of this sample agreed with those from other sources. The x-ray data gave the cube edge as 8.247 ± 0.005 A. H. E. Messmore

New occurrences of hot-spring calcite. E. Balogh. *Erdélyi Muzeum, Cluj-Kolozsvár* **1937**, 362–6; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 622.—Microscopic examn. of the hot-spring calcite of the Valea Vinului-Borpatak Valley shows it to consist of interlaced fibers of calcite, and not, as hitherto supposed, of aragonite. The peculiar form is attributed to the presence of NaCl in the water from which it has crystd. NaCl is also present in the calcite of Corund-Korond where a similar deposit occurs, also formerly regarded as aragonite. C. A. S.

Protocalcite. E. Balogh. *Erdélyi Muzeum, Cluj-Kolozsvár* **1937**, 147–55; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 621–2.—At one place in the Comarnic-Komarnic cave (Banater gebirge) there occurs a layer of flock-like material resembling a fungus growth, 1–2 mm. thick, consisting of a loosely knotted mass of needle-like crystals at most 0.5 mm. long by 1 3 μ broad, consisting of calcite, but apparently a mono- or tri-clinic form. The name protocalcite is suggested. C. A. Silberrad

Transparent green pyroaurite from Ontario. H. V. Ellsworth. *Univ. Toronto Studies, Geol. Ser.* No. 42, 33–45(1939).—Certain specimens of a dolomite from lot 27, concession X, Calvin Township and 3.5 miles east of Rutherglen, Ontario, contain small quantities of the rare mineral pyroaurite. The mineral occurs as small greenish barrel-shaped hexagonal crystals rarely over 1 mm. in diam. By analysis the formula is $Fe_2O_3.6MgO.CO_2.12.5$ or 13 H_2O. Upon heating to 150° 5 mols. of H_2O is lost, 2 mols. is lost between 210 and 260° and the remaining 5.5 mols. is expelled between 260 and 270°. After complete dehydration the mineral is a rich brownish color and still uniaxial or very slightly biaxial. H. E. Messmore

Vesuvianite from Great Slave Lake region, Canada. V. B. Meen. *Univ. Toronto Studies, Geol. Ser.* No. 42, 69–74(1939).—Vesuvianite occurs in Pre Cambrian sediments, near a granite contact, at Turnback Lake, about 40 miles north of Great Slave Lake, Northwest Territories. The vesuvianite crystals were up to 1 in. in length, chocolate brown with a greenish tint, and prismatic in form. $n\omega = 1.712$, $\epsilon = 1.708$. The vol. of the unit cell is 2890 cu. A., d. = 3.432. The mol. wt. of the unit cell is 6011; the cell const. is $(Ca, Mn, Na, K)_{27.72}(Al, Be, Fe^{++}, Fe^{+++}, Mg, Ti)_{27.72}Si_{35.41}(O, OH, F)_{168}$. H. E. M.

The cation exchange and swelling of montmorillonite as a function of preheating. U. Hofmann and Jo. Endell. *Beiheft Z. Ver. deut. Chem.* No. 35, *Angew. Chem.* 52, 708–9(1939); cf. *C. A.* **31**, 6147[1].—Exptl. data are presented for two Ca and Na bentonites each and one mica mineral. The bentonites lose the property of intercryst. swelling between 300 and 490°. References. K. Kammermeyer

Thorium-free monazite from Llallagua, Bolivia. Samuel G. Gordon. *Notulae Naturae, Acad. Natural Sci. Phila.* No. 2, 1–7(1939).—The monazite occurred in 3 different veins in the Sn mine in Llallagua as flesh-pink coarse granular aggregates of crystals intergrown with cassiterite, in a matrix of rounded fragments of quartzite cemented together by "wood tin," and as twin-crystals of monazite with small transparent crystals of wavellite on clear prismatic crystals of quartz, resp. No Th was detected by spectrographic examn. of the monazite from the first vein. No evidence of a greater concn. of radioactive material than is found in ordinary earth was obtained. Tables showing chem. analyses and crystal angles of 14 forms are given, together with details of methods of analysis and drawings of crystals. The crystals are translucent, sp. gr. 5.173, have $n\alpha = 1.785$, $\beta = 1.787$ and $\gamma = 1.840$ all ± 0.005, and are usually prismatic in habit with twins (simple contact pairs or cruciform penetrations) quite common. Edward B. Sanigar

Wulfenite, ralstonite and thomsenolite from Ivigtut, Greenland. Samuel G. Gordon. *Notulae Naturae, Acad. Natural Sci. Phila.* No. 11, 1–2(1939).—The thomsenolite occurs in tubular crystals often in fan-shaped aggregates. The ralstonite is present as small colorless limpid octahedra and cubo-octahedra, n (immersion method with Hg yellow light) being 1.399 ± 0.001. The wulfenite crystals are grayish yellow in color with an adamantine luster. Edward B. Sanigar

Anthraxolite from South Nahanni River, Northwest Territories. R. L. Rutherford. *Univ. Toronto Studies, Geol. Ser.* No. 42, 123–5(1939).—A specimen from Meilleur Creek, a tributary of the South Nahanni River, consisted of brittle anthraxolite with small fractures filled with quartz. This material consisted of moisture 1.9, volatile matter 6.0, fixed C 85.9 and ash 6.2%. It is brittle and breaks with pseudo-rectangular cleavage into small chunks. Anthraxolite is a coal-like material resulting from the metamorphism of petroleum. The chem. analysis of this material should be compared on an ash-free basis. H. E. Messmore

Theories of formation of ore deposits. Edson S. Bastin. *Sci. Monthly* 49, 538–47(1939).—A review. E. H.

Geology and tectonics of the Outokumpu ore field and region. Heikki Vayrynen. *Bull. comm. géol. Finlande* No. 124, 91 pp.(1939)(in English); cf. Haapala, *C. A.* 30, 7508[6]; Mäkinen, *C. A.* 32, 2471[1].—Mainly geol. The ore body is estd. to contain 20 million metric tons of ore, rather uniform in compn., and averaging SiO_2 40, Fe 27.5, S 27, Cu 4.5, Zn 1.0, Co 0.2, Ni 0.1%, as well as 1 g. Au and 12 g. Ag per metric ton. The mineralogic compn. is quartz 40, pyrite 31.7, chalcopyrite 13, pyrrhotite 13.8 and sphalerite 1.5%. Michael Fleischer

Mindanao Mother Lode Philippines. Lawrence E. Smith. *Mines Mag.* (Colo. School of Mines) 29, 563–6(1939).—A survey of mining operations. Values are in the form of very fine Au assocd. with Cu sulfides and quartz. Among the minerals in the vein are chalcopyrite, chalcocite, enargite, cuprite, malachite, native Cu, pyrite, galena, sphalerite, calcite and quartz. Leopold Scheflan

Association of gold, tungsten and tin at outpost islands, Great Slave Lake. J. E. Hawley. *Univ. Toronto Studies, Geol. Ser.* No. 42, 53–67(1939).—In the Great Slave Lake region, minerals of W, Sn, Cu and Mo are assocd. with Au in mineralized zones in which also are found quartz-mica lenses of pegmatitic aspect, contg. staurolite and andalusite, the latter enclosing grains of blue corundum. Many quartz bodies range in size from 1 to 10 ft. in width, and 10 to 50 ft. in length. Segregations of muscovite and biotite, locally altered to chlorite, are contained within the quartz, as well as 3–4 in. crystals of red andalusite. Minor constituents are magnetite, ilmenite and specular hematite. The quartz is usually coarse-grained, glassy and white in color. Where replacement of andalusite has been extensive, grains of corundum are enclosed by mica. The Au appears to be the last mineral deposited and occurs as disseminated flakes, and as is so often the case no indication is available as to the temp. of the Au deposition. Samples from this region contained 0.05–0.20% Sn and nil–1.20% W, although no definite Sn mineral could be identified. The W occurred in either ferberite or powellite. H. E. Messmore

Copper-tourmaline-hematite veins at Highland Valley, B. C. John S. Stevenson. *Univ. Toronto Studies, Geol. Ser.* No. 42, 127–33(1939).—The veins are in close proximity to a quartz diorite area. They vary in width from that of a knife edge to 4 ft., but 10 in. is most common. The vein-filling material consists of tourmaline, quartz, specular hematite, magnetite, chalcopyrite, pyrite and chlorite, chalcocite, malachite and limonite. Tourmaline is by far the most abundant of these minerals, consisting of 5–90% of the veins. H. E. Messmore

Iron ore on the Mediterranean seaboard. J. H. Goodchild. *Mining Mag*, 61, 333–43(1939).—The geochem. significance of an occurrence of Fe ore on the coastal fringe of the Sierra Nevada is discussed. This is another example of the segregation of a weak base, Fe (cf. *C. A.* 32, 8993[4]). A comparison of such segregations assists in the study of the growth of new bodies that depend on the concn. of strong bases. In the case now considered, photographic illustrations of exposures are held to demonstrate clearly the processes of concn. or growth of rich ore bodies. Immense quantities of unstable matter are supposed to have disappeared during earlier stages, resulting in a greater freedom for the development of new structures. In most cases studied, the ore tends to reveal the effects of internal rather than external force; the dynamical aspect of the iron ore bodies, of the marbles, of the schists is that of growth in a field of potential. Here in Spain the stratigraphy indicates how and when such fields may develop. A. W. Furbank

Tungsten-molybdenum deposits of Kok-kul in the High Altai. G. D. Zinov'ev, V. D. Timofeev and T. M. Zubkov. *Soviet Geol.* 9, No. 8, 53–65(1939).—A list of 38 minerals found is given. Green, almost isometric, wolframite contg. 75.08 WO_3, 20.75 MnO and 2.30% FeO, and long, gray, layer wolframite contg. 76.72, 15.65 and 8.17%, resp., were found, as well as molybdenite, scheelite, etc. Com. exploitation is considered feasible. **New tungsten deposits of Cis-Balkhash in Kazakhstan.** A. S. Osipov. *Ibid.* 66–71.—The wolframite contains 75.65% WO_3, 10.86 MnO, 12.05 FeO and 0.25 $(Ta + Cb)_2O_5$. F. H. Rathmann

A recent discovery of commercial titanium ore. C. C. Coulter. *Mining J.* (Phoenix, Ariz.) 23, No. 9, 7(1939).—Large quantities of Ti ore of satisfactory com. grade were discovered in Hidalgo County, New Mexico, near the Arizona border. It is a replacement deposit of contact metamorphic origin. The content of TiO_2 increases with depth. The deposit averages 70 ft. in width and approx. 1000 ft. in length. Leopold Scheflan

Fluorite deposit of Chebargatin. E. K. Tepikin. *Soviet Geol.* 9, No. 7, 95–6(1939).—The CaF_2 content is 48–92%, av. 75%. 200,000 tons of ore is commercially available. F. H. Rathmann

Illinois mineral industry in 1938. A preliminary statistical summary and economic review. Walter H. Voskuil and G. N. Oliver. *Illinois State Geol. Survey, Rept. Investigations* No. 56, 5–24(1939). E. H.

Subsurface geology and oil and gas resources of Osage County, Oklahoma. II. Townships 22 and 23 North Ranges 8 and 9 East. C. T. Kirk, H. D. Jenkins, Otto Leatherock, W. R. Dillard, L. E. Kennedy and N. W. Bass. *U. S. Geol. Survey, Bull.* 900-B, 47–82(1939); cf. *C. A.* 32, 7864[5]. E. H.

The Pre-Cambrian. M. E. Wilson. *Trans. Roy. Soc. Can. IV* 33, 1–9(1939).—An outline of the history of geol. nomenclature and classification in the Can. Shield in Canada. It is suggested that wherever a continuous succession of lavas or sediments or both be found in the Archian complex of the St. Lawrence province they be given local series names and that Keewatin or Timiskaming be used only to designate groups of Keewatin or Timiskaming type; that as geol. controls detailed maps of areas favorable for study be made and that maps more detailed than 1 mile to 1 in. be extended to other favorable geol. areas beyond those where important mineral deposits have been made. J. W. Shipley

The Temiskaming-Keewatin problem in the Rouyn-Harricanaw region, N. W. Quebec. H. C. Gunning and J. W. Ambrose. *Trans. Roy. Soc. Can. IV* 33, 19–47 (1939).—No subdivision of the Archian in N. W. Quebec into Timiskaming and Keewatin can be made. Sediments and volcanic rocks are much mixed. Sediments were deposited at various places along with the volcanic rocks with interfingering and interbedding common. Beds of chloritic tuff in the Cadillac sediments indicate that some explosive eruptions occurred after Cadillac sedimentation was under way. Beds of iron formation and magnetite are restricted to the Cadillac group. The fine-grained sediments of the Kewagama and Cadillac groups are indistinguishable. J. W. Shipley

Calcium silicate and calco-magnesian rocks of the Mts. de Forez. Jean Jung and Paul Sainfeld. *Compt. rend.* 209, 887–8(1939).—Although the wollastonite-pyroxene-anorthite rock reported in 1883 from St.-Clément (Puy-de-Dôme) could not be identified, rock approximating to its description was found at St.-Bonnet-le-Courreau (Loire) forming enclaves of gneiss in anatectic granite and consisting of amphibolite and pyroxenite and often contg. almandine and in places fibrous wollastonite. C. A. Silberrad

The stock of "suzorite" in Suzor Township, Quebec. Carl Faessler. *Univ. Toronto Studies, Geol. Ser.* No. 42, 47–52(1939).—An outcrop of suzorite occurs in the Little Pichui River region of the Greenville area of Suzor Township, Laviolette County, Quebec. The outcrop forms an ellipse, with diams. of approx. 200 ft. and 1100 ft. The contact between the suzorite and the country rock could not be found, but in its place was a zone about 2 ft. wide of highly altered and loosened rock material originating from both the country rock and the instrusion. The suzorite rock is massive, dark-brown, very soft, coarse-grained and has little mech. strength. Sp. gr. is about 2.9. The rock contains over 50% of a dark-brown mica, some red feldspar, greenish pyroxene, and some colorless apatite. H. E. Messmore

Vesicular carbonaceous sediments in Lake of the Woods region. Jas. E. Thomson. *Univ. Toronto Studies, Geol. Ser.* No. 42, 141–50(1939).—Five exposures of vesicular graphitic sediments were observed in the Lake of the Woods region, the best occurring southwest of the town of Kenora on the northwest corner of Corkscrew Island. In one 25-ft. section of sedimentary material 6 vesicular chert zones were present with intervening nonvesicular material. Freshly broken samples of this chert show a dense black groundmass with spherical cavities varying in size from 0.5 in. to microscopic size and resembling pumice in structure. Some cavities are empty; some contain rounded masses of graphite. These sediments contain 92–97% SiO_2, 1.6–2.6 Al_2O_3 with smaller amts. of Fe, Ca, etc., and 0.40 to 1.98% C. The origin of this material is not definitely known. H. E. Messmore

Iron-stained rocks, Hematite Stream, North Canterbury. J. Healy. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* 13, 116(1938–39).—The hematite occurs in 2 types of bedded deposits which appear to be assocd. with igneous extrusions of the pillow-lava type. The more common type is a red siliceous rock occurring in alternating bands of hard and friable material and interbedded with greywackes. The other type consists of crushed quartz and jaspillite beds with a development of Fe-staining along the joint planes. Six samples contained an av. of 7.5% Fe. K. D. Jacob

Weathering in sunny places. A. Kieslinger. *Jber. Sonnenblickver.* 1937, 22–32(1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, 1939, 665–6.—Examples of phys. and chem. weathering, especially of marbles and calcareous schists of the Hohen Tauern, are described. In particular while phys. weathering results in projecting knobs of feldspar the presence of pyrite through production of H_2SO_4 produces hollows ("pit-weathering"). Knob-weathering is also conspicuous in the breunnerite serpentine, where in apparent contradiction it is the easily sol. carbonate that forms the knobs projecting from the silicates. "Lath-weathering" results from hardening owing to invading solns. along small fissures in the gneiss. C. A. S.

Hydrothermal reactions—Mg hydrosilicate (Jander, Fett) 6.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Thermal metal recovery. E. J. Kohlmeyer. *Metall u. Erz.* **36**, 545–51(1939).—A general discussion of theory and practice of thermal methods for recovery of metals from ores. H. Stoertz

The role of Emulsol X-l in flotation. J. Bryant Kasey. *Mining J.* (Phoenix, Ariz.) **23**, No. 15, 3–4(1939).—Emulsol X-l, by enlarging the fine bubbles of a pine-oil froth, permits rapid drainage of gang; it does not vary in frothing properties over a wide range of pH values and has practically no collecting properties. Com. applications of this new frothing agent are described. L. Scheflan

Flotation of gold. I. N. Plaksin. *Zolotaya Prom.* **1938**, No. 10, 6–11; *Khim. Referat. Zhur.* **2**, No. 4, 98 (1939).—The upper limit of the flotation corresponds to 0.3–0.4-mm. size of the particles. The sulfide Au ores are most easily floated. The quartz and the oxidized ores usually can be floated by an addn. of the sulfide ores or by the addn. of special reagents which favor the formation of a stable froth. In a no. of cases not only Au, but also other valuable components of the ore (Cu, Pb, As, etc.) are sepd. by flotation. Before flotation the coarse particles of the Au must be sepd. by concn. on tables, in settling app., etc., as well as by amalgamation. A proper selection of the concn. of the pulp is important. The optimum ratio is solid:liquid = 1:2.5. W. R. H.

A new method of cyanidation of the sulfide gold ores and concentrates with addition of hydrophilic colloids. B. Nevskiĭ. *Zolotaya Prom.* **1938**, No. 10, 32; *Khim. Referat. Zhur.* **2**, No. 4, 98(1939); cf. *C. A.* **32**, 6989⁸.—The cyanidation of the sulfide Au ores is difficult because the ores are not easily wetted by solns. The hydrophobic properties of such ores are increased by flotation. The hydrophobic properties of the ores can be reduced by an addn. of hydrophilic colloids (saponin, tannin). The use of these substances increases the extn. of Au, as shown by the preliminary expts. at the Moscow Inst. of Noble Metals and of Gold. W. R. Henn

Addition to amalgamation plants. N. Antonova. *Zolotaya Prom.* **1938**, No. 6, 24–5; *Khim. Referat. Zhur.* **2**, No. 4, 98(1939).—Only 50–60% of Au contained in ores is extd. in the amalgamation plants. It is proposed to treat the tailings by flotation with butyl xanthate (70 g./ton) and pine oil (45 g./ton) with an addn. of soda and water glass. This gives a concentrate contg. about 88% of Au and about 98% of Zn of the tailings. The concentrate contains 38–41% of Zn and is ready for treatment in the metallurgical plant. The tailings from flotation yield a baryta concentrate (after a treatment on concn. tables) contg. about 85% of $BaSO_4$. The total extn. of Au from the ore is approx. 85%. W. R. Henn

Three years of operation with a Hadsel mill. Geo. A. Bell. *Eng. Mining J.* **141**, 32–3(Jan., 1940).—A new type machine employed by Demonstration Gold Mines, Ltd., at Baguio, P. I., is economical in work and maintenance, mechanically sound and ideal for 1-stage crushing of wet, sticky ore. A flowsheet is shown of the crushing and fine grinding section of the 250-ton cyanide unit, also a side elevation of the Hardinge-Hadsel mill. W. H. B.

An American view of the copper industry. E. O. Sowerwine. *Mining J.* (Phoenix, Ariz.) **23**, No. 14, 2–4(1939). —Descriptive. Leopold Scheflan

East Bohemian copper ore deposits (Sudeten province). Fritz Hoffmann. *Metall u. Erz* **36**, 513–16, 529–31 (1939).—Cu occurs as sulfide, with Cu ranging from 0.67 to 2.17%, and is found in microscopic state of division in coal. The coal is burned away, Cu loss being very small in this process. The product is further enriched by flotation. H. Stoertz

Styrian ores in greater Germany. Hans Malzacher. *Metall u. Erz* **36**, 497–504(1939).—Fe ore deposits in the Styrian district of Austria are described. These ores contain only traces of S and are almost completely free of P. High Mn content makes them very suitable for steel manuf. H. Stoertz

Black copper of Yunnan. H. Bruce Collier. *J. Chem. Education* **17**, 19–21(1940). E. H.

Smelting methods in the years 1937 and 1938. V. Tafel. 3 *Metall u. Erz* **36**, 384–9, 415–19, 441–8, 484–91, 504–7, 516–22, 532–41(1939).—A description of smelting methods used for Pt, Au, Ag, Cu, Bi, Pb, Sn, Sb, Zn, Cd, Hg, Ni, Co, Al, Mg, Ca, Ba, V, Cr, Mo, Mn, Be, Si, Se, Te and Tl. Electrolytic as well as dry and wet methods are discussed, and ore dressing methods are considered. H. S.

Effect of carbon dioxide on the velocity of reduction of magnetite and hematite by carbon monoxide. E. P. 4 Tatievskaya and G. I. Chufarov. *J. Phys. Chem.* (U. S. S. R.) **13**, 495–501(1939).—Exptl. data over the temp. range 400–900° and at gas pressures of 0.02 to 0.20 mm. Hg are given. The retarding effect of CO_2 on the initial stage of reduction of magnetite is considerable at 500° and negligible at 900°; CO_2 does not affect the initial reduction of hematite, but after a Fe_3O_4 surface layer has once formed, hematite behaves the same as magnetite. F. H. Rathmann

The open-hearth furnace and its auxiliaries. G. D. 5 Tranter. *Metal Progress* **37**, 34–8(1940).—A practical summary of recent improvements in design and operation. The use of hot metal, bottom patching, control, waste heat boilers, and insulation, combustion and temp. control are described. W. A. Mudge

Resistance-heated electric crucible furnaces for light metals. O. Gengenbach. *Elektrowärme* **9**, 227–34(1939). —Furnaces for melting small amts. of Al and Mg are re- 6 viewed and crucibles with resistance heating discussed in particular. Graphite crucibles have the great advantage of not adulterating the melt but the heat cond. is rather low so that the heating elements (when heating from the outside) must have a temp. of about 1050–1100° for a crucible temp. of about 900°. This reduces the life of the heating elements. Also the graphite burns off if the inner wall is not covered by the melt. Cast-Fe crucibles, sometimes 7 with low Cr content, give good service, if often cleaned as molten Al dissolves Fe. Molten Mg does not dissolve Fe so that cast Fe crucibles can very well be used for melting Mg. Care must be taken that the scale (oxide) which forms on the outside does not come in contact with the liquid metal as they form together a mixt. burning with an explosion. The energy consumption is about 1 kw. per 1 kg. crucible content. Melting processes are discussed and directions for pouring Al and Mg given in detail; furnaces 8 are described. M. Hartenheim

Apparatus for preparing gas for heat-treating metals. A. A. Shmykov. *Vestnik Metalloprom.* **19**, No. 4, 38–42 (1939).—An app. is described for prepg. gases used in heat-treating metals. The app. includes an NH_3 dissociator, chambers for the partial combustion of H_2 and purification of the gas, and dehydration cooling chamber for freezing out the moisture as well as absorber for drying the 9 gas and flow controllers. B. Z. Kamich

Progress in metals—specifications for furnace castings. W. L. Nelson. *Oil Gas J.* **38**, No. 22, 72(1939).—A tentative standard specification by alloy-casting manufacturers and consumers. Analysis and phys. properties of castings for various services are given. W. Andrew Wright

Aging of metals after deformation. N. F. Lashko, G. Ya. Slobodyanyuk and A. K. Khodulin. *Vestnik Metalloprom.* **19**, No. 4, 69–76(1939).—Aging of various steels contg. up to 1% Mn was investigated by variations in the

temp. of cold brittleness. Deformation was made by stretching, compressing, and bending followed by artificial aging at 250° for 30 min. Plastic deformation by various methods increased the temp. of cold brittleness. Deformation by compression had a greater effect on temp. of cold brittleness than the same degree of deformation by stretching. B. Z. Kamich

Metals in drilling. V. Drilling hoists. W. L. Nelson. *Oil Gas J.* **38**, No. 21, 54(1939).—The metallurgy of parts for drilling hoists. **VI. Engine and machine castings.** W. L. Nelson. *Oil Gas J.* **38**, No. 26, 57(1939).—The specifications of iron and steel castings for engine and machine parts are listed as to chem. analysis and phys. properties. **VII. Crown and traveling blocks.** W. L. Nelson. *Oil Gas J.* **38**, No. 25, 49(1939).—A discussion of the metallurgy of the various parts of crown and traveling blocks. W. Andrew Wright

Production of forged rolls for cold rolling. R. Scherer. *Stahl u. Eisen* **59**, 1105–11(1939).—The recent increase in cold rolling and generally higher roll pressures has focused attention on roll failures. Formerly cold rolls were cast but lately forgings have been used. The most frequent compn. is 0.9% C and 1.8% Cr. For long life, care must be taken in the grinding and polishing as well as in the compn., melting, and forging. Sharp changes in section must be avoided and gradual fillets used. Experience has shown that rolls not bored for water cooling have longer life, but are harder to produce. Defects such as flakes, fissures, sand seams, and grinding checks are illustrated. In water-quenching care must be taken to avoid troostite formation at the surface and to obtain a gradual transition from the hard surface to the softer center. In grinding care is necessary to avoid local overheating. During rolling damage may be caused by dragging or sliding of the work and too high roll pressures which may soften the surface and cause spalling and cracking. Also in *Heat Treating Forging* **25**, 598–603, 615–16(1939). S. Epstein

Fatigue of boiler iron. N. N. Afanas'ev. *Vestnik Metalloprom.* **19**, No. 3, 28–34(1939).—Fatigue tests were made at 350° and room temp. during repeated bending in one plane with boiler Fe of av. quality and contg. about 0.15% C. The fatigue limit at 20° was lower than at 350°. Holes in the sheets reduced the fatigue limit by 30%. Compression increased the fatigue as did aging after riveting. The results are compared with literature data. B. Z. Kamich

Crosshead speed vs. rate of strain. Lawford H. Fry. *Metal Progress* **37**, 46–8(1940).—An analysis of expts. with screw-driven testing machines shows loading of the tensile specimen at a continually varying and increasing speed despite const. screw speed. The yield point of steel is not very sensitive to these normal variations. The hydraulic machine permits rate of loading at any desired value. W. A. Mudge

Barrel polishing. E. G. West. *Machinery* (London) **54**, 713–17(1939).—Gray-iron castings fill a horizontal steel barrel from ¾ to completely full. A quantity of sand or emery is added together with water. Sometimes 10% H_2SO_4 is added to remove scale. Speed varies from 25 to 50 r. p. m., total running time from 36 hrs. for malleable to 60 and 90 hrs. for gray cast iron. Brass and bronze are usually treated in an open, inclined barrel. Sand, powd. pumice, coke, glass powder or other abrasive can be used in quantities varying up to the same vol. as the charge; the mixt. is covered with water. The operation takes 10 to 20 hrs. Light loading and low speed are used for Al castings. Richard P. Seelig

Pickling tanks. L. Vielhaber. *Emailwaren-Ind.* **16**, *Beizerei* 33(1939).—The best solution of the pickling-tank problem is to line concrete or masonry tanks with acid-proof metal, such as bronze or monel. Rubber-lined iron tanks are mentioned. M. V. Condoide

The study of metals and alloys. Morris Cohen. *Rept. New Engl. Assoc. Chem. Teachers* **41**, 52–8(1939).—An address. Leopold Scheflan

The deep drawing of aluminum. A. G. C. Gwyer and P. C. Varley. *Metallurgia* **21**, 19–22(1939).—The ability to withstand repeated drawing operations without intermediate anneals, its lightness, nontoxicity, cleanliness and attractive appearance are increasing the use of Al and its alloys for deep drawing. Favorable drawing conditions are discussed. Expts. showing that the thinner the metal the less is the possible reduction on drawing are described. J. L. Gregg

Absorption of hydrogen by chromium. I. E. Adadurov, N. I. Pevnyi, I. F. Rivlin and G. P. Kushta. *Trudy Kharkov Khim.-Tekhnol. Inst. S. M. Kirova* **1**, 12–18 (1939).—Cr does not absorb H. The addn. of Cr to Pt does not affect its catalytic activity. The increase of stability of Pt and of steels contg. Cr is connected with the fact that Cr does not absorb H and when added to alloys lowers their absorbing power. M. V. C.

Nickel additions to high purity copper. Torsional properties. W. F. Chubb. *Metallurgia* **21**, 7–10(1939).—Torsional properties of O-contg. and O-free Cu alloys contg. up to 0.5% Ni were detd. The rigidity modulus and the limit of proportionality increased as the Ni content increased. J. L. Gregg

Nickel's role in milling equipment. John E. Kerr. *Eng. Mining J.* **140**, 54–7(Dec., 1939).—Alloyed steels and irons contg. Ni find many uses in crushing and grinding and ore treatment. Ni-Cr-Mo steels possess excellent depth-hardening characteristics and are used in jaw crushers, gyratory crushers and rolls. Tables show the materials used for these parts. W. H. Boynton

Pure silicon. A. B. Kinzel and Thomas R. Cunningham. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* **1138**, 5 pp.(1939).—A review of properties of Si in purified form of com. product. C. L. Mantell

Making engravers' zinc. A. G. Arend. *Process Engraver's Monthly* **45**, 254–5(1938); *Phot. Abstracts* **19**, 50.—Improved methods of manuf. include the use of electromagnetic fields to heat and stir the metal without oxidation. Sheets are rolled separately, the tolerance of thickness being maintained to 0.001 in. Pits in the finished sheet are punched-up from the back, an optical device being used to control the operation. The plates are polished, and test etchings are made on them before they are placed on the market.

Pseudomorphism in quenched and tempered railroad tires. I. N. Frantsevich, M. S. Borushko and N. F. Lashko. *Stal* **9**, No. 7, 51–60(1939).—Specimens of steel contg. 0.52% C quenched from 880° and drawn at 540–700° developed a pseudomorphic sorbitic structure oriented like martensite which had a low impact resistance. This structure can be avoided by quenching from 950°. H. W. Rathmann

The prevention of flakes by holding railroad rails at various constant temperatures. R. E. Cramer and E. C. Bast. *Trans. Am. Soc. Metals* **27**, 923–30(1939); cf. *C. A.* **33**, 6769⁴.—The formation of flakes was prevented in 2-ft. specimens of 131-lb. rails by holding 3 hrs. at 1100°F.; 4 hrs. at 900° and 700°F.; and 5 hrs. at 500°F. The steels contained 0.75 to 0.78% C and were etch tested for 1 hr. in a 50% soln. of hot HCl followed by a ½-hr. immersion in a hot 10% soln. of Na-pyrophosphate to prevent corrosion. W. A. Mudge

Rational method of cementation. M. M. Kuz'mina. *Mashinostroitel* **8**, No. 6, 17–19(1938).—In testing various carburizers the following mixt. was found most satisfactory: 75% charcoal, 15% Na_2CO_3 and 10% $BaCO_3$. Addn. of $CaCO_3$ and NH_4 salts did not affect noticeably the cementation of the steels. Tentative heat-treatments are suggested. B. Z. Kamich

Synthesis of gas suitable for cementation operations. S. I. Privalov, M. K. Chukavin, V. P. Zueva and N. P. Ogarkov. *Vestnik Metalloprom.* **19**, No. 1, 85–91(1939).—Gas suitable for cementation of steel was prepd. by synthesizing CH_4 from CO, CO_2 and H_2 in the presence of a catalyst comprising pumice stone impregnated with a soln. of $Ni(NO_3)_2$ contg. 15% powd. Cr_2O_3 and reduced with H_2 at 350°. The life of the catalyst was indefinite provided the temp. did not exceed 500–600° and its surface remained clean. The temp. in the retort was maintained at 400°. If the starting gas has 4–5 times as much H_2 as

$CO + CO_2$ the resulting gas did not have to be scrubbed of the CO_2. B. Z. Kamich

Anticementation paste. A. Agatov. *Khim. Mashinostroeinie* 8, No. 6, 29–30(1939).—A paste suitable for protecting metal surfaces against cementation consists of CuCl, $CuCl_2$, PbO and Bakelite. The following 3 modifications were used with satisfactory results: (1) 500 g. CuCl and 200 g. red lead are mixed with an alc. Bakelite soln. (4:1) to give the desired consistency; (2) 600 g. $CuCl_2$ and 200 g. red lead are mixed with 600 cc. alc., cooled, and mixed with 150 cc. of the alc. Bakelite soln.; (3) 300 g. $CuCl_2$, 300 g. CuCl and 200 g. red lead are mixed with 300 cc. alc., cooled, and mixed with 200 cc. of the alc. Bakelite soln. Best results were obtained with the first type of paste. B. Z. Kamich

Quantitative investigation on the cementation of iron and the decarburization of steels. Seizirо Simura. *Tetsu-to-Hagane* 25, 851–74(1939).—In investigating the cementation of pure iron and the decarburization of carburized high-carbon steels, a dilatometer was used whereby the inner atm. was varied freely. Thin tubular specimens, 8 mm. in outer diam., 0.75 mm. in wall thickness and 100 mm. in length, were taken as standard; they were heated at certain const. temps. for a long time in a tubular heat-resisting carburizing box, in which solid carburizing materials were placed or gas current was applied. Since austenite increases remarkably in vol. as the cementation proceeds, and contracts by decarburization, the stages of various changes accompanied with these phenomena were traced under various conditions in the carburizing box, by measuring the dilatation of the specimens. M. Ishida

The Rennerfelt-Kalling process for the decarburization of solid granulated pig iron. B. Kalling and I. Rennerfelt. *Stahl u. Eisen* 59, 1077–82(1939).—See *C. A.* 33, 7253[3]. S. Epstein

Influence of graphite ladle additions on the mechanical properties of gray cast iron. A. H. Dierker, R. P. Schneider and H. H. Dawson. *Ohio State Univ. Studies, Eng. Expt. Sta. Repts.* 8, No. 4, 3–6(1939).—Certain foundries add graphite to the iron at the spout during casting, especially to thin sections. The influence of such addns. (approx. 0.11%) using various grades of graphite was investigated. Chill depth, transverse strength, deflection, tensile strength and Brinell hardness were detd. on bars of difference size. Graphite ladle addns. definitely reduce the chilling tendency of cast iron; any appreciable influence on the mech. properties could not be found, however. Richard P. Seelig

Antifriction and abrasion-resisting qualities of cast iron. Masahiro Tasaki. *Imono* 9, 613–21(1939).—Coulomb's law of friction holds for steel-to-steel contact up to a load of 7 kg./sq. cm. and the coefficient of static friction is independent of the load; above the load limit, the coeff. becomes large and variable with accompanying roughening of the friction surface. Between 2 cast-iron surfaces and between surface of steel against a Cu-Pb alloy the law holds up to a load of 280 kg./sq. cm. and the friction surfaces remain smooth. The coeff. of kinetic friction varies with the speed and does not obey Coulomb's law. M. Ishida

Porous antifriction metalloceramic cast iron. M. Yu. Bal'shin and N. G. Korolenko. *Vestnik Metalloprom.* 19, No. 3, 34–41(1939).—The manuf. of metalloceramic cast Fe is discussed under the headings of (1) selection of materials, (2) grinding of the cast iron, (3) preliminary annealing, (4) mixing, (5) pressing, (6) caking and (7) reduction to proper size. The best starting materials are cast irons with min. content of Si and other addns. Si should not exceed 1.7% and optimum content is 0.8–1.3%. White cast iron is preferred to gray or forged because it is not subject to flattening and cleavage during grinding although the last 2 types are to some extent more economical. Grinding of the material to 150–200 mesh is considered adequate for cold pressing. The most satisfactory annealing temp. is 750–900°, the duration depending upon the degree of graphitization desired. Pressure required varies from 2000 to 5000 kg./cm. depending on porosity and size of the object. The optimum temp. for caking is 1100° for periods of 30 min. to 2 hrs. and cooling should be done gradually. B. Z. Kamich

Original or remelted aluminum for deoxidation of iron and steel? E. Piwowarsky. *Aluminium* 21, 744–6 (1939).—The discussion of the question whether for the purpose of deoxidizing steel, Al should be used as it comes from the original raw material (as is still requested by many steel men) or if remelted Al could be used, leads P. to conclude that at present the quality of remelted Al is perfectly satisfactory for all industrial purposes. Two types of remelted Al are now on the market (in Germany) of the following compns.: USt-AlI, less than 4% Cu, trace Sn, less than 0.05% Zn, less than 0.3% Pb, higher than 92% Al, the remainder Fe-Si-Ni-Mg-Mn-Ti-Co-Cr; and USt-AlII, with less than 4% Cu, less than 0.2 Sn, less than 0.8 Zn, less than 0.5% Pb, more than 90% Al, and the same remainder as for USt-AlI. As only 0.05–0.1% Al is used for deoxidation, and 0.2% max. for nonaging material, the other impurities which get into the steel with it are of no practical consequence. Si, on the contrary, is of great advantage, as even a few tenths % of Si makes the steel less sensitive to overheating, and above 0.2–0.4% increases the uniformity of hardening in eutectoid steels. Killed steel and cast steel require addns. of 0.15–0.45% Si; for deep-drawing steels the content must be kept below 0.1%. C steels for tool steels should contain 0.1–0.6% Si, structural steels 0.1–2.0%, alloy steels for hot working 0.2–2%, and spring steels 1–3%. M. H.

Steel in 1939. Walter S. Tower. *Mfrs. Record* 109, No. 1, 32(1940).—A survey. Leopold Scheflan

Measuring the temperature of molten steel. Takesi Sugano. *Tetsu-to-Hagane* 11, 933–44(1939).—To increase the accuracy of measurement by the optical pyrometer, a study was made of (1) the personal error of the observer, (2) the emissive power of the liquid steel in the ladle, and (3) fall of the temp. in the ladle during pouring. By the simultaneous use of a standard lamp and a standard optical pyrometer, (1) was detd. to be ±10° at the max. By comparing the true temp. detd. by the Fe-W thermocouple with the brightness temp. by the optical pyrometer, av. emissivities in the ladle were for the arc furnace, 0.55 for Ni-Cr steel, 0.56 for Cr-Mo-steel, 0.53 for Ni-Cr-Mo steel and 0.52 for carbon steel. In the open-hearth furnace, where the data are insufficient, the total av. value is 0.52. The fall of temp. during the pouring of the steel in the ladle varies for slag thicknesses of 0.4 to 1.0 cm. from 40° to 20°. M. Ishida

Manufacture of nitrided crankshafts. S. F. Yur'ev. *Vestnik Metalloprom.* 19, No. 5, 41–55(1939).—The warping of crankshafts during the nitriding process is caused by (1) internal stresses resulting from previous treatment and (2) the wt. of the crankshaft at high temps. The first type of deformation can be decreased by properly regulating the manuf. of the crankshafts while the second type can be eliminated completely by constantly rotating the crankshafts during the heating, nitriding and cooling. A nitriding furnace suitable for these operations is described. B. Z. Kamich

Nitriding of steel during quenching. V. I. Prosvirin and A. P. Belova. *Vestnik Metalloprom.* 19, No. 6, 57–64(1939).—Ball-bearing, C and other steels were nitrided in NH_3 (dissocn. 50–70%) at temps. of 550–840° prior to quenching by dropping them through a vertical tubular furnace into the oil without coming in contact with the air. The treated steels showed high surface hardness and resistance to corrosion in water. The anticorrosive properties were not decreased by tempering after quenching. The specimens showed no brittleness and the surfaces were highly wear-resistant. B. Z. Kamich

Nitriding of high-speed tool steel. N. P. Petrov. *Stanki i Instrument* 9, No. 5, 20–3(1938).—High-speed tool steel contg. C 0.72, Cr 3.80, W 17.27 and V 0.54% was nitrided in a closed bath contg. NaCN 90.7, KCN 3.75% and the rest Na_2CO_3 and NaOH. Nitriding was done at 520, 550 and 580°. At 520° the av. increase in the depth of the nitrided layer was 0.8–1.0 μ/min., at 550° it was

1.8–2 μ/min., and at 580° it was 2.0–2.5 μ/min. The nitrided layer had a finely dispersed eutectoid structure devoid of carbides. Cutting tools were also nitrided at 500, 520, 560 and 580° for 5, 10 and 15 min. The increased cutting speed was dependent upon the bath compn., time of nitriding and temp. Tools which were nitrided for 15 min. at 520° in the above bath showed the greatest increase in speed of cutting. B. Z. Kamich 1

Introductory study of the nitriding of hardened high-speed steel by the use of molten cyanides. J. G. Morrison and J. P. Gill. *Trans. Am. Soc. Metals* **27**, 935–1011 (1939).—The paper is a detailed introduction of a comprehensive investigation of the process of surface hardening of hardened high-speed steel by immersion in a molten cyanide bath. The steel used contained 0.70 C, 4.0 Cr, 1.01 V and 18.0 W. Part I includes (*a*) compn. of nitriding bath, (*b*) chem. reactions which take place, (*c*) aging of the bath, (*d*) contamination of the bath from Ni pots or thermocouple protection tubes, and (*e*) the galvanic characteristics of the bath. Part II includes (*f*) N content, (*g*) hardness, (*h*) microstructure, and (*i*) appearance of nitrided surfaces. The appendix gives a method of analysis for *detg. N in steel.* W. A. Mudge 2

Isothermal transformation in steels. Edmund S. Davenport. *Trans. Am. Soc. Metals* **27**, 837–86(1939).—See *C. A.* **34**, 3557. W. A. Mudge 3

Heat-treatment and properties of EI172 steel—a substitute for high-speed steel. M. V. Pridantsev. *Stal* **9**, No. 7, 35–40(1939).—Steel contg. C 1.00–1.15, Si 1.1–1.7, Cr 11.0–13.0, V 2.1–2.5, Mn less than 0.4 and S and P less than 0.03% was quenched from 1100–1300° in oil and drawn at 500–575°. The best quenching temp. was 1240°. The hardness after quenching was 53–58 Rockwell "C." The optimum draw was at 540° for 6–8 hrs., preferably followed by 2 1-hr. draws at the same temp. Drawing increased the hardness of the steel to 62–64 Rockwell "C." The residual austenite in the steel after quenching did not transform into martensite while at the drawing temp. but changed in compn. owing to pptn. of carbides. After drawing the austenite transformed into martensite on cooling below 200°. The hardness of this steel was slightly less at 500–600° than that of steel contg. W 18, Cr 4 and V 1%. When V was on the high side the lower C limit was definitely too low to obtain max. hardness. H. W. Rathmann 4

The tempering of high-speed steel. Morris Cohen and P. K. Koh. *Trans. Am. Soc. Metals* **27**, 1015–46(1939).—X-ray, hardness, sp. vol., elec. resistance, metallographic, dilatometric and magnetic measurements on hardened specimens, tempered at several temps. for periods ranging from 1 min. to several hundred hrs., were made to study the mechanism of tempering and secondary hardening of 18–4–1 high-speed steel. Four overlapping stages are defined; (1) decompn. of tetragonal martensite with pptn. and coalescence of cementite in a highly alloyed ferrite matrix, (2) pptn. of complex carbides from the residual austenite, (3) transformation of the residual austenite, and (4) pptn. of complex carbides from the ferrite matrix of state (1), and the re-soln. of the cementite. The initial softening of the steel is due to (1); the secondary hardening results from (2) and (3); and (4) is not encountered in normal com. tempering. Single tempering does not remove internal stresses because austenite transforms during cooling. Multiple tempering results in incremental transformation during successive coolings so that stresses are relieved and martensite is toughened by the subsequent heatings and may therefore result in slightly lower secondary hardness than the single tempering. W. A. M. 5

New high-speed tool steel. K. Osipov. *Novosti Tekhniki* **1939**, No. 23–24, 28–9.—The following 2 steels were found satisfactory as substitutes for the high-speed steel of 18% W: (1) C 1–1.2, V 2.8–3.5, Mo 2.5–3.5, W 2.5–3.2, and Cr 3.8–4.5%, and (2) C 1.2–1.4, V 3.5–4.5, Mo 2.5–3.5, W 2.5–3.2 and Cr 3.8–4.5%. The steels should have the following properties: Brinnel hardness of 255–207 after annealing, 63–65 Rockwell scale C after hardening, and 63–65 Rockwell scale C after tempering. Heat-treatments are described. B. Z. Kamich 6

A hardenability test for shallow-hardening steels. W. E. Jominy. *Trans. Am. Soc. Metals* **27**, 1072–85 (1939).—The end cooling principle has been successfully used to measure the hardenability of shallow-hardening steels contg. 0.96 to 1.20% C. Descriptive details are given and illustrated with curves and photomicrographs. W. A. Mudge 7

Experiments with a new creep-testing apparatus on the course of time-elongation curves of different steels. H. Esser and S. Eckardt. *Arch. Eisenhüttenw.* **13**, 209–22 (1939).—Discrepancies often found in the results of evaluation of creep curves led to a modification of the app. generally used in which special attention was paid to concussion- and vibration-free suspension and the lever system for the transmission of the movement of the specimen to the recorder. Curves taken with this instrument show that in a test of 4.5 hrs. duration the curve has a purely parabolic shape up to 500°, so that they can be represented by a straight line in a double-logarithmic coördinate system and extrapolated more correctly. A test of 12–14 hrs. is considered sufficient for all practical purposes. This parabolic shape permits the derivation in connection with discontinuity points, of certain characteristics of the material which is explained at length by the example of several plain and alloy steels. Nine references. M. H. 8

Effect of temperature of hardening and tempering upon the deformation of steel. A. I. Samokhotskiĭ. *Vestnik Metalloprom.* **19**, No. 4, 67–9(1939).—Specimens of steel contg. C 1.04, Mn 0.22, Si 0.27, P 0.031 and S 0.017% were quenched at 700, 740, 770, 800 and 830° and tempered at 300, 500 and 700°. Regardless of the quenching temp. an increase in the tempering temp. gradually decreased the sp. vol. in comparison with the quenched condition. By increasing the quenching temp. the sp. vol. increased. B. Z. Kamich 9

Effect of austenite grain size in steel upon the properties of machine parts. I. S. Kozlovskiĭ and M. A. Leonov. *Vestnik Metalloprom.* **19**, No. 2, 56–73(1939).—This paper deals with the relation between the grain size of austenite and the mech. properties of machine parts made on a mass production basis. On the basis of the results obtained suggestions are offered for obtaining the proper grain size for various machine parts. B. Z. Kamich 10

Improvement of the quality of freshly rolled steel on storage. István Gállik. *Anyagvizsgálók Kozlönye* **17**, 79–105(1939).—Aging had no effect on the tensile strength, yield point and uniform elongation of steel samples. The increase of total elongation was little, that of contraction and cohesion, however, more important. The qual. improvement is not connected with hardness or the shape of the sample. Soft steels reached the max. qual. improvement within 1–2 days; hard rail steels, in a few weeks. Mn retards the improvement. The foot of the fresh rail is regularly better than the head. On aging the head improves more than the foot. S. S. de Finály 11

Resistance to caustic embrittlement of boiler plate steel in relation to its aging sensitivity, heat-treatment and aluminum content. F. Nehl and W. Werner. *Stahl u. Eisen* **59**, 1155–7(1939).—Six boiler steels contg. 0.06 to 0.23% C, two of which were killed with Al to give 0.048 and 0.044% residual Al contents were cold worked and aged to det. the loss in impact resistance on aging. Also "Jones" caustic embrittlement tests were made, by immersing specimens bent by clamping into hot caustic $Ca(NO_3)_2$ and NH_4NO_3 solns. The specimens were tested in the as-rolled condition, after annealing, after quenching, and after normalizing and annealing. There was no definite relationship between aging embrittlement by the impact test and caustic embrittlement. Low-C steels showed a greater tendency to intercryst. corrosion by caustic than higher-C steel; so that it appears best for resistance to caustic not to go under 0.15% C. On the addn. of Al caustic embrittlement was only improved when the steel contained over 0.04% Al. In steels not killed with Al or with low Al content resistance to caustic embrittlement was obtained by annealing or normalizing and annealing at 730° to 780°, or quenching and similar annealing. Air cooling from the annealing temp. gave about 12

the same resistance as furnace cooling. Surface decarburization materially raised the sensitivity to caustic embrittlement. S. Epstein

The study of high-strength austenite stainless steel sheet for aircraft construction. Sozi Hori and Hidekiti Ōhasi. *Tetsu-to-Hagane* **25**, 875–80(1939).—The yield strength or proportional limit of 18/8 stainless steel was raised to a considerable extent by the age-hardening of previously cold-rolled sheet. This property, however, can be developed most effectively by the addn. of some suitable elements to the plain 18/8 alloy. The authors made some expts. on the influence of Ti (5 test samples with a Ti content varying from 0 to 1.6% were used) on the mech. properties in connection with the degree of cold-rolling and the temp. of aging which they receive. From the results, it is found that a marked increase of the yield strength can be obtained by the appropriate aging of cold-rolled sheet to which 0.5% Ti has been added. M. I.

Chromium steel castings. E. K. Smith. *Metal Progress* **37**, 49–54(1940); cf. *C. A.* **33**, 1029.—Mech. properties and some uses for cast 21 to 29% Cr steels, low-Cr (1 to 5%) steels and Cr-Ni steels, contg. 15 to 29% Cr and 8 to 35% Ni, are given. Cb reduced impact strength of the high-alloy stainless steels and of the low-Cr steels; with the latter, resistance to oxidation was increased and air hardening prevented. Ti prevented air hardening and lowered yield and tensile strengths. The use of N-bearing ferro-Cr improved grain refinement and ductility. W. A. Mudge

Characteristics of 5.0 and 7.0 per cent chromium steels with varying molybdenum and vanadium content. W. G. Hildorf, C. L. Clark and A. E. White. *Trans. Am. Soc. Metals* **27**, 1090–1113(1939).—Short-time tensile tests at room temp. and 1200°F., rupture tests at 1200°F., and microscopic examns. of 5.0 and 7.0% Cr steels, contg. 0.50 to 2.0% Mo and 0.0 to 1.0% V (21 steels total), show that: (1) Mo continuously increases strength, and (2) V decreases strength when greater than 0.50% for the 5.0% Cr steel and greater than 0.18% for the 7.0% Cr steel. The difference is explained microstructurally in terms of the amt. of the δ-constituent present. For the same Si content, an increase in Cr from 5.0 to 7.0% did not appreciably influence the rupture strength of the steels contg. 1.0% or more Mo, while it decreased the rupture strength of all steels contg. V. W. A. Mudge

The effect of columbium on the properties of chromium-molybdenum and nickel-chromium steels. Yukio Ōkura and Zinpei Ōmori. *Tetsu-to-Hagane* **11**, 964–75(1939).—Effects of Cb on the phys., mechanical, chem. and welding properties of low-carbon Cr-Mo steels and medium-carbon Ni-Cr steels were studied, Cb is a valuable alloying element for low-alloy steels; it has several advantages such as inhibition of air-hardening characteristics, increasing strength at high temp., increasing corrosion and oxidation resistances and the improvement of weldability, although it lowers the impact value. M. Ishida

A discussion of leaded steels. F. J. Robbins and G. R. Caskey. *Trans. Am. Soc. Metals* **27**, 887–915(1939); cf. *C. A.* **33**, 9248[5].—Addns. of 0.15 to 0.30% Pb were made to several selected grades of S. A. E. C steels. Mech. and machining tests and the practical aspects of fabrication show an opportunity for substantial savings in machining and fabrication costs without sacrifice in mech. dependability. Production difficulties are rapidly being overcome. Detailed data are given. W. A. Mudge

Nickel steel and the hydrogenation of fuels. Charles Berthelot. *Japan Nickel Rev.* **7**, 323–36(1939); cf. *C. A.* **33**, 2088[3]. E. H.

Steel, corrosion-resisting; bars and forgings. *Federal Specification* QQ-S-763, Apr. 20, 1939. **Aluminum-alloy, forgings, heat-treated.** *Ibid.* QQ-A-367a, May 23, 1939. **Tubing, aluminum-alloy (AL-3) (aluminum-manganese).** *Ibid.* WW-T-788a, May 23, 1939. Washington: Supt. of Documents, U. S. Govt. Printing Office, 5c each. L. Wilson Greene

Recent progress on the structure of alloys. Mario A. Rollier. *Chimica e industria* (Italy) **21**, 615–22(1939).—A summary, including tabulated data on alloys contg. the rarer metals. A. W. Contieri

The microscopic analysis of intermediate phases in some age-hardening alloys. Marie L. V. Gayler (Mrs. Haughton). *Proc. Roy. Soc.* (London) **A173**, 83–91 (1939); cf. *C. A.* **33**, 2456[1].—It was shown in a 4% Cu-Al alloy that the intermediate phase α $CuAl_2$ is metastable and becomes β $CuAl_2$ on aging by a polymorphic change. In a 4% Cu, 0.5% Mg alloy a second intermediate phase assocd. with ternary Al-Cu-Mg was observed in the (100) planes. In Duralumin a buff-colored phase distinct from either α or β was found after prolonged aging at 250°. 11 references. J. N. Lynn

Modern antifriction alloys. L. G. Gershenfel'd. *Mashinostroitel* **8**, No. 4, 17–21(1938).—The properties, compn., and manuf. of modern antifriction alloys are reviewed. B. Z. Kamich

Lapping hard-alloy tools. E. N. Malyuchkov and M. L. Gol'man. *Stanki i Instrument* **9**, No. 11, 21–6(1938).—Results are given on lapping with various abrasive materials and with B carbide pastes. Under factory conditions lapping can be carried out with B carbide pastes (graining 28–40 μ) and a circular speed of the disk equal to about 1 m./sec. B. Z. Kamich

Magnetic test for superstructure in Permalloy. S. T. Pan. *Phys. Rev.* **56**, 933–6(1939).—A search for indirect evidence for the existence of superstructures $FeNi_3$ and Fe_2Ni_2 by a magnetic method is described. A preliminary test showed that annealing at a temp. around 450° for 2 to 3 days followed by slow cooling at a rate of about 40° per hr. increased the satn. magnetization by 3.9% in Permalloy and 1.3% in Hipernik over the values found after the alloys were quenched from above 900°. These increases were reproducible and the magnitudes depended somewhat on the exact way of heat-treatment. It would thus appear likely that at least partial order exists in the annealed alloys. Subsequent measurements taken after annealing at, and quenching from, different temps. showed that the assumed ordering process takes place in temp. ranges 640–400° and 800–400° for the 76Ni-24Fe and 50Ni-50Fe alloys, resp. The satn. magnetization vs. temp. curves for the quenched and the slowly cooled states of the 76Ni-24Fe alloy have also been taken. At a rather slow cooling rate, about 30° per day from 700° to room temp., the increase in satn. value at room temp. is 6.0%. All these results agree very well with those just reported by McKeehan and Grabbe (*C. A.* **33**, 3650[8]) and Leech and Sykes (*C. A.* **33**, 7168[2]). B. Lewis

The use of aluminum alloys in aircraft. W. C. Devereux. *Metallurgia* **21**, 11–14(1939).—The advantages of Al and its alloys are pointed out and some parts made from such materials are described. J. L. Gregg

Diffusion of beryllium in copper and its alloys. N. A. Filin and M. L. Shtil'man. *Metallurg* **13**, No. 12, 93–8 (1938).—Cu, Cu-Al alloy contg. 8% Al and Cu-Zn alloy contg. 10% Zn were heated in Be powder at 600–800° for 2–10 hrs. and depth of Be diffusion was detd. by hardness tests and micrographic examn. Max. diffusion at 800° in 10 hrs. was 1 mm. for pure Cu, 3 mm. for the Cu-Al alloy and 0.3 mm. for the Cu-Zn alloy. H. W. R.

Chromium alloys for use in the chemical industry. V. K. Pershke and Kh. L. Tseĭtlin. *Khim. Mashinostroenie* **1938**, No. 5, 42–4; *Khim. Referat. Zhur.* **2**, No. 3, 137 (1939).—Cr cast iron (35% Cr) and Cr steels (EYa I (18% Cr and 8% Ni), EI 100 (12% Cr, 8% Mn and 3% Ni), EZh 17 (17% Cr), "furadit" (26% Cr), "fekhral" (14% Cr and 4% Al)), ordinary cast iron, boiler iron, Pb and Al were tested for corrosion resistance in the processes of acetylation, chlorination, phenylation, tolylation, sulfonation and nitration. The Cr cast iron and steels corroded not at all, or much less than ordinary cast iron, Fe, Pb and Al. W. R. Henn

Constitution and properties of ternary alloys in the copper corner of the copper-aluminum-beryllium system. N. A. Filin and L. L. Iokhel. *Metallurg* **13**, No. 12, 81–92 (1938).—The ternary diagram for Cu alloys contg. up to 5% Be and 12% Al consists of 4 fields of primary pptn., ternary solid soln. α, β, β′ and γ′. Addn. of Al increases

the hardness of Cu-Be alloys in the cast, annealed or quenched state. All alloys lying outside of the α solid soln. are subject to aging at 200–400°. H. W. R.

Copper-rich nickel-aluminum-copper alloys. III. Effect of heat-treatment on microstructure. W. O. Alexander. *J. Inst. Metals* **65**, Advance copy No. 853, 14 pp.(1939); cf. *C. A.* **33**, 2090⁸.—Of the series, only the alloys of 5% Ni with 1.5–4% Al, 6% Ni with 1–4% Al, 8% Ni with 1–6% Al, and 10% Ni with 1–4% Al showed thermal arrest points. After various heat-treatment they were examd. microscopically. The limit of α solid soly. decreases with the fall of temp. and results in the rejection of the 2 phases θ(Ni_3Al) and NiAl either singly, or, within a narrow compn. range, together. Alloys such as one contg. 6% Ni and 6% Al are hardened by pptn. of the Ni-Al solid soln. phase from the solid soln. Alloys contg. a relatively small percentage of Al and of varying Ni content are heat-treatable owing to the breakdown of the α solid soln. to produce θ(Ni_3Al). The breakdown mechanism is indicated by the microstructure after heat-treatment: (1) recrystd. stable "ragged" grain structure as developed by quenching and tempering treatments, (2) lamellar sepns. of α and θ in eutectoid form accompanied by recrystn. of the matrix, obtained by cooling at the rate of 33° per day from 700° to 600° and (3) the trefoil ppt. of θ(Ni_3Al) in α obtainable by cooling at 10° per day from 700° to 600°. David Margolis

Effect of composition upon physical and chemical properties of 10-carat gold alloys. Tracy C. Jarrett. *Trans. Am. Inst. Mining Met. Engrs., Inst. Metals Div.*, Pub. No. 1122, 9 pp.(1939); cf. *C. A.* **33**, 9257⁹.—When Ag is present in 10-carat Au alloys, the corrosion loss is greatly reduced and the brass yellow color softened. Ni is a whitening agent, tending to reduce corrosion loss and increase hardness, yield point, and ultimate strength, whereas Zn produces an opposite effect. C. L. M.

Aging of lead alloys containing antimony, calcium and barium. V. S. Lyashenko. *Metallurg* **13**, No. 12, 99–113 (1938).—Aging of binary Pb alloys contg. Sb 1.46–11.72, Ca 0.045–0.166 or Ba 0.24–0.53% at 20°, 50° and 80° was detd. by tensile tests, hardness, elec. resistance and microstructure. All alloys showed an increase in tensile strength and hardness. Elec. resistance of Pb-Sn and Pb-Ca alloys decreased on aging while that of Pb-Ba alloys showed no change. Max. tensile strength of Pb-Ca alloys was attained in 1–3 days at 80° after which it steadily decreased. H. W. Rathmann

The constitution of dilute alloys of lead with sulfur, selenium and tellurium. J. Neill Greenwood and Hill Wesley Worner. *J. Inst. Metals* **65**, Advance copy No. 854, 11 pp.(1939).—Solid soly. at 300° of S, Se and Te in Pb contg. less than 0.0005% impurities was studied by means of microexamn. and detns. of m. p. and elec. resistance. Deoxidized and vacuum cast ingots prepd. from dild. mother alloys were extruded into wire 2 mm. in diam. for the elec. resistance detn. by means of the Kelvin double bridge by Wolff. M. ps. were detd. to 0.1° with a modification of the app. used in m.-p. detns. of org. compds. The elec. resistance of wires (1) with 0.001% and 0.0005% S is 0.1% higher than for similarly treated pure lead; (2) with up to 0.001% Se in solid soln. is lowered from 20.65 micro-ohms/cc. for pure Pb at 17° to 20.61; (3) with 0.004% Te in solid soln. is increased to 20.70 micro-ohms/cc. The solid soly. in Pb of (1) S is less than 0.0001% by wt. or 0.0006 at. %; this is also the limit of soly. in molten Pb at the m. p. (2) Se is 0.0015% (0.004 at. %) at 300° and a eutectic of 0.005% Se m. 0.2° below the m. p. of Pb. (3) Te is 0.004% (0.0065 at. %) at 300° and a eutectic of 0.025% Te m. 0.7° below the m. p. of Pb. While the actual depression of the f. p. of Pb by addn. of these elements is small, the at. depression is very high. David Margolis

Alloys of magnesium research. IX. The constitution of the magnesium-rich alloys of magnesium, aluminum and silver. J. L. Haughton. *J. Inst. Metals* **65**, Advance copy No. 856, 10 pp.(1939); cf. *C. A.* **33**, 9259⁶.—The constitution of the alloys of Mg with Al and Ag were investigated up to about 40% Al and 50% Ag. A ternary eutectic is formed at 403° ± 1°, contg. 52.8% Mg and 28.2% Ag. Contour plans of the liquidus, secondary sepn., solidus and solid soly. surfaces are reproduced, as well as a no. of vertical sections through the constitution prism in the neighborhood of the ternary eutectic limits. Ag up to 5.2% is sol. in the Al-Mg solid soln. at the ternary eutectic temp. and does not appreciably alter the solid soly. of Al in Mg. Al up to 8.8% is sol. at the same temp. in the Ag-Mg solid soln. but it greatly reduces the soly. of Ag in Mg. The addn. of the third component to either of the binary systems increases the steepness of its solid soly. curve. 21 references. Iver Igelsrud

Tensile properties of rolled magnesium alloys. I. Binary alloys with aluminum, antimony, bismuth, cadmium, copper, lead, nickel, silver, thallium, tin and zinc. John C. McDonald. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1110, 12 pp.(1939).—The tensile properties of several Mg-base binary alloys were studied in rolled strips by a method adopted especially to eliminate comparisons in which the effects of working would play a part; rather, the results are comparable strictly on a basis of alloy compn. The following elements were studied up to the limits indicated: 9% Al, 7 Sb, 9 Bi, 18 Cd, 10 Cu, 11 Pb, 9 Ni, 12 Ag, 15 Tl, 10 Sn, 8 Zn. According to the desirability of their effect, the order becomes: Zn, Al, Ag, Tl, Cd, Ni, Cu, Sn, Pb, Bi and Sb. C. L. Mantell

Gas industry and nickel alloys. Giro Tomita. *Japan Nickel Rev.* **7**, 303–12(1939). E. H.

A high-strength silicon-brass die-casting alloy. A. U. Seybolt and Bruce W. Gonser. *Trans. Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1123, 10 pp.(1939).—After the tensile properties of a wide range of chill-cast Cu alloys of relatively low m. p. were investigated, an alloy was developed that seemed promising for use in die casting. This alloy has the following compn.: 83% Cu, 10 Zn, 5 Si, 1 Al and 1 Mn. C. L. Mantell

A study of the distribution of structural and physical characteristics throughout castings of red brass. A. M. Rahm. *Trans. Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1117, 15 pp.(1939).—Examn. of grain size, density, hardness, microstructure, chem. compn. and the usual data obtainable from tensile and impact tests was undertaken to establish general laws connecting various characteristics of red brass castings or to supply, at least, a substantial amt. of material for further study. C. L. Mantell

The system iron–cobalt–beryllium. W. Köster. *Arch. Eisenhüttenw.* **13**, 227–30(1939).—Fe forms with $FeBe_2$ a eutectic alloy series; the eutectic temp. is about 1155°, the Be content at this temp. is 11% and that of the α-solid soln. 8%. Co forms with CoBe also a eutectic alloy series, eutectic temp. is 1115°, and the Be content of the eutectic is 4.2% and of the γ-solid soln. 2.5%. The extent of the homogeneous space of the α-solid solns. solidifying from the melt was investigated in particular for ratios of Fe:Co of 2:1, 1:1 and 1:3. Four different phases were found in the Fe–Co–Be system: the α and γ phases and 2 Be compds. A mixing gap exists between the Fe-Be and Co-Be compd. in the solid state; this gap is, however, not very wide. The eutectic three-phase equil. melt E_1 (= solid soln. α_1 + $\vartheta_1(FeBe_2)$) of the system Fe–Be shifts with addn. of Co gradually to lower temps., and ends, together with the equil. of melt E_2 (= solid soln. ϑ_2 + solid soln. η_2) on the four-phase plane $\alpha_2 S_1 \vartheta_2 \eta_2$, at about 1100°. The Curie temp. of the homogeneous Fe-Co solid solns. is greatly reduced by Be; Co counteracts this reduction, as for the same Be content the Curie temp. increases considerably with Co content. The α-solid solns. with up to 25% Co and 7.5% Be were quenched from 1100° and tempered for half an hr. at different temps. Up to 300°, hardness of the alloys did not change, from 300 to 500° it increased, and beyond 500° it decreased slowly.

Max. Brinell hardness occurred at about 500° tempering with about 620 kg./sq. mm. Alloys poor in Co and Be attain the max. at about 700°. The hardness of the homogeneous alloys increases with increasing Co and Be. An alloy with 5% Co, 7.5% Be was tested for magnetic behavior for the same hardening treatment. The satn. increases from 400° tempering temp. to a max. at 700°; the change in magnetic satn. is a measure for the disintegration of the oversatd. solid soln. The sepn. is accompanied by an increase of remanence and coercive force, both of which reach a max at 600°; hardness increases from 300° and reaches max. at 500°. The Fe-Co-Be alloys are similar in magnetic behavior to the Fe-Co-W alloys, except that in the former the satn. increases with the disintegration. Martensitic alloys with 50% Co and 2–5% Be had immediately after quenching 80–100 oersteds coercive force at a satn. of 16,000 and a remanence of 5000 gausses. The binary Co-Be alloys with 1–2% Be were homogeneous after quenching with a correspondingly low coercive force of 5 oersteds, which increased on tempering at 700° to 80,105 oersteds at 14,000-gauss satn. and 5000-gauss remanence. M. Hartenheim

Electrical method for end-point determinations in the jet test for thickness of metal plating. A. J. Lindsey and L. E. Terrett. *J. Soc. Chem. Ind.* **58**, 288–90(1939).—In the jet test (cf. Clarke, *C. A.* **31**, 2568[9]) a stream of corrosive liquid is impinged under controlled conditions upon the surface of a plated metal object. The time required for the plating to disappear is a measure of the thickness of the metal coating. In order to overcome the difficulty in visually observing the disappearance of the plating, an elec. method was devised to indicate the instant at which complete removal occurs. In the app. developed a connection is made from a calomel electrode to the running stream of etching fluid by means of an agar jelly-KCl bridge tube. The standard jet and funnel reservoir are the same as those described by Clarke. The specimen, from one corner of which the plating has been removed, is connected to a galvanometer; the e. m. f. generated by the system being balanced by adjustment of a potentiometer. The latter is fed by a single-Pb accumulator. The galvanometer is a central zero pointer instrument with 0.2 microamp. per division sensitivity and a resistance of 770 ohms. The potentiometer resistance is rated at 400 ohms. To det. the thickness of a coating, the etching stream and a stop-watch are started simultaneously and the galvanometer needle is adjusted to the zero point as soon as possible. The watch is stopped when the needle begins a steady drift from zero. Tabulated data for visual and elec. measurements are given for the following coatings: Ni on brass, Zn on Fe, Cd on Fe, Ni on Ni-Ag (low Ni) and Ni on Ni-Ag (high Ni). The elec. method is quicker and more accurate than the visual method. L. Wilson Greene

Properties of hot galvanizing—shaping of pieces to be galvanized. W. Thalemann. *Oberflächentech.* **16**, 193–5, 199–202, 209–10(1939).—The importance of hot galvanizing as protection from corrosion is discussed. Of the yearly world production of 1.5 million tons Zn, about 900,000 are used for galvanizing, and 90% of the latter for hot galvanizing. The 3 processes most applied are the wet-galvanizing, in which the object is transferred wet as it comes from the pickling process after rinsing into the Zn bath, the dry-galvanizing, in which the object is first treated and dried before being placed in the bath and by which highly bright surfaces are produced, and the patenting galvanizing process, in which a thin Zn layer is deposited on a Pb or Pb-Mn layer. A corrosion-proof Zn layer is obtained only in a pure Zn bath, impurities might later create local elements which start corrosion. Hot galvanizing cannot be applied to objects which have to keep their dimensions exactly or the mech. properties of which suffer by the temp. applied. A galvanized object has 7 layers: (1) Fe, (2) diffusion layer ZnFe, (3) $FeZn_8$, (4) $FeZn_7$ (both hard Zn layers), (5) Zn (melt), (6) Zn hydroxide and (7) Zn carbonate. The impurities in the bath should not exceed 2%, viz., Fe 0.03, Pb 1.2, Cu 0.05, Al 0.05, Sn 0.20 and Zn oxide 0.05%. 1 An immersion of 1–3 min. produces a thickness of $^1/_{10}$–$^1/_{20}$ mm., about 350–700 g. per sq. m. for sheets, structures, etc., and for tubes $^1/_5$–$^1/_{10}$ mm. The thickness of the injurious hard Zn layers should be as small as possible. Besides control of correct temp. of about 460°, the immersion time should be as short as possible depending on the shape and wt. of the object. The life of a Zn coating deposit depends on the purity and thickness of layer 5, 2 its density, kind of attacking agents and on the mech. and phys. influences of the surrounding, in particular on the hard Zn layers. The corrosion resistance of Zn decreases in the order named for the following agents: atm. substances in closed rooms; cold tap and river water; air, rain and wind according to temp.; damp cement and plaster; sea water, about 2–4 times as corrosive as river water; distd. water, about twice as corrosive as sea water and 7 times as river water; emanations from wood, in- 3 creasing from maple over oak and pine to lime tree; free alkalies, e. g., K and Na lyes; dild. acids, acid oils, ammonia, all Cl compds., and galvanic elements and stray currents. Hints for selecting the proper galvanizing process, treatment of objects before and after, testing of the deposit especially for porosity, and cost (applicable mainly for German conditions) are discussed. Twenty references. M. Hartenheim

Types of attack of steel by zinc in hot galvanizing. W. 4 Radeker and R. Haarmann. *Stahl u. Eisen* **59**, 1217–27 (1939).—A discussion of attack by Zn on steel in galvanizing, particularly in galvanizing tanks. An instance is shown where ArCoFe was attacked much less by Zn than a 0.19% C 0.30% Si steel; but in very low-C steels with 0.05% C max. increase of the Si to 2% appreciably lowered the attack by Zn. In galvanizing tanks stresses formed by local differential heating of the tanks appeared to be a 5 cause of intercryst. Zn penetration and cracking. S. Epstein

Aluminum as surface protection for steel. H. Hoff. *Aluminium* **21**, 755–9(1939).—Al is capable of forming, in aq. solns., firmly adhering, electrically insulating films of alumina on steel; these protect the Fe as long as they exist (just as Zn deposits from hot-galvanizing). Tests made with a 0.5-mm. Fe sheet over 5 years show a change in wt., if the original sheet is 100%, after coating with Al 6 103, Zn 85, Pb 60, Sn 50%, without coating 15% of the original wt. by atm. corrosion. Several methods were developed to plate steel with Al by cold working, as no satisfactory process similar to hot-galvanizing has been found because of the formation of a compd. $FeAl_3$ at 500–600°. Rolling-on of Al foil can be done at room temp. or also at 300–400°; the latter process has the advantage that good adhesion is obtained with less rolling pressure while the cold process saves the heating furnace and inci- 7 dental work. Si and Mn added to Al shift the formation of $FeAl_3$ to higher temps. but as the best protection is obtained with pure Al, often a double-plating process is applied, at first an Al-Si alloy is rolled on upon which a pure Al foil is then rolled. The steel should be as soft as possible and free of Si, P, S and Cu as all these shift the recrystn. point to higher temps. so that it can be annealed (e. g., for deep-drawing steel) without changing the de- 8 sired structure. A steel was developed which has a recrystn. temp. of 520–530° and a beginning $FeAl_3$ formation at 570° which can be soft-annealed even after strong cold-deformation without defects. Al-plated Fe sheets can replace to a certain extent galvanized or tinplate; it has been employed successfully for bearing bushings as these have no tendency to freezing, and for the canning industry. M. Hartenheim

Some aspects of corrosion. Carlos J. Forn. *Bol. obras sanit. nacion* (Buenos Aires) **3**, 182–91(1939).—An 9 address, with special reference to *water systems*. O. W. Willcox

Discussion of problems related to corrosion and means of its prevention. V. A. Kistyakovskiĭ, *et al.* *Vestnik Akad. Nauk S. S. S. R.* **1938**, No. 6, 50–6; *Khim. Referat. Zhur.* **2**, No. 2, 135–6(1939).—A decrease of the S content from 0.06 to 0.02% increases approx. 10% the corrosion resistance of steel. An increase of the Cu content to over

0.25–0.30% does not increase noticeably the resistance of the steels. For best results the Cu content should be not over 0.3%. Discussion is included of subterranean corrosion of metals, means for overcoming the elec. corrosion processes, photoelec. methods of the investigation of the initial stages of corrosion, corrosion processes with the evolution of H, formation of oxide films on metals, prepn. of bright Zn deposits on metals by the electrolytic method, passivity of metals, passivators and activators, action of I vapors on metals, photogenetic phenomena during corrosion and effect of lyophilic colloids on the velocity of soln. of Fe in strong electrolytes. W. R. Henn

Corrosion tests with EW-treated and lacquered alloy sheets of the type aluminum-copper magnesium and those plated with aluminum, copper and magnesium. H. Wolf and H. Tuxhorn. *Aluminium* **21**, 767–72(1939).—The EW-process has the advantage over the MBV-process in that a purely chem. surface protection can be applied also to Al alloys contg. Cu; these, however, must be covered by an addnl. lacquer film. As the absorption of the EW layer for lacquers is inferior to that of the MBV layer a special lacquer was developed for this purpose (of a Na silicate base) which is colorless and gives an excellent corrosion protection; it dries quickly and requires only 5 g. per sq. m. surface. Numerous tests in atm. corrosion and HCl solns. were made and show almost no change of surface after 60 days. M. Hartenheim

A comparison of methods for estimating soil corrosivity. K. H. Logan. *Oil Gas J.* **38**, No. 27, 130, 133, 134, 136, 137, 138, 159, 160(1939).—A statistical comparison of available methods. W. Andrew Wright

Low-tin solders. V. S. Chernyak. *Mashinostroitel* **8**, No. 1, 44–6(1938).—The mech. properties of low-Sn (10–15%) solders were detd. at room temp. and at −183° and the results compared with high-Sn (33–50%) solders. The impact toughness of the low-Sn solders was 25–30% lower than for high-Sn solders, the decrease being considerable for those contg. Sb. The tensile strength of the low-Sn solders was about the same as that of high-Sn solders while those contg. Sb were stronger than 50% Sn 50% Pb. Brass sheets which were lap soldered were 15% weaker than those soldered with high-Sn solders. The impact toughness and tensile strength of 15% Sn solder increased at low temps. B. Z. Kamich

Aluminum metallurgy. P. G. Elizarov and V. N. Verigin. Russ. 51,794, Sept. 30, 1937. Al_2O_3 is heated *in vacuo* or in a neutral reaction zone in the presence of carbon-free reducing agents having a higher b. p. than Al that produce gaseous reaction products.

Ore froth flotation. Benjamin R. Harris. U. S. 2,177,985, Oct. 31. In a froth flotation process such as one for sepg. silica and siliceous materials from ores, use is made of a small proportion of a compd. of the general formula $RO[(CHY)_r(CHY)_rO_t]_m(CHY)_vN(A)\equiv$, where R is a high-mol.-wt. org. radical, Y is alkyl, H, or hydroxy or other anion, A is an anion, *s*, *m* and *v* are whole numbers, *r* is zero or a small whole number, *t* is zero or one, and at least one of the three indicated valence bonds attached to N is satisfied by a radical of the class consisting of alkyls, cycloalkyls, alkylols, aryls, aralkyls, aralkylols, and the radical of a heterocyclic ring of which the nitrogen is a member. In such compds., A may be a halogen and R may be a fatty acid acyl radical contg. 8–18 C atoms (numerous examples being given).

Briquetting finely powdered ores, blast-furnace dust, etc. Hungária Mütrágya-, Kénsav- és Vegyi Ipar R. T. Hung. 121,371, Sept. 1, 1939. The powd. substances are mixed with carbohydrate-contg. binders (molasses, sucrose, etc.) and pressed to briquets.

Apparatus (with an internal revolving cylinder and helical blades) suitable for sintering zinc ores, etc. Emil J. Bruderlin (to American Smelting and Refining Co.). U. S. 2,178,366, Oct. 31. Various structural and operative details.

Metallurgical furnace. William B. Boggs and Jack Parry (to M. H. Detrick Co.). Can. 385,083, Nov. 14, 1939. Structural details.

Automatic fuel regulation of open-hearth furnaces. Wm. C. Hogg and Lewis Rumford, II (Rumford to United States Steel Corp.). U. S. 2,177,805, Oct. 31. App. for regulating the temp. in a furnace of the regenerative type provided with means alternately to supply heat energy at opposite ends thereof, includes a pair of radiation-sensitive devices adapted to convert radiant heat energy into elec. energy having an intensity bearing a known relation to the temp. inducing the heat energy, means to irradiate each of the devices by radiation emitted by a portion of the inner refractory lining of the furnace which during each alternate heating of the furnace is subjected to the max. heating effects, means adapted to be actuated by the elec. energy thereby produced in the devices to lower and to increase the supply of heat energy to the furnace as the intensity of the elec. energy approximates max. and min. limits, resp., and means automatically to connect to the heat supply control means first one and then the other of the devices in synchronism with the alternate supplying of heat energy at opposite ends of the furnace.

Furnace regenerators suitable for use with open-hearth metallurgical furnaces. Wm. J. Irwin. U. S. 2,178,794–5, Nov. 7. Various structural features.

Water-cooled tuyères for blast furnaces or the like. Karl Steinbacher. U. S. 2,178,654, Nov. 7. Structural details.

Aluminum. Soc. internationale des carburants "Brevets Consalva," Soc. anon. holding. Belg. 432,408, Feb. 28, 1939. Alum is purified, converted to a mixt. of Al and K sulfides, and this mixt. reduced.

The treatment of waste materials containing aluminum and paper. Soc. de recherches et d'entreprises. Belg. 432,217, Feb. 28, 1939. The material is heated at a temp. sufficient to carbonize the paper without attacking the Al, disintegrated and sepd. pneumatically. The material is oxidized at a temp. sufficient to destroy the coloring matters without oxidizing the Al. If it is desired to recover the paper also, the waste material is treated with water or steam at above 100°, and sepd. by levigation.

Porous metal objects. Chester Tietig. Can. 385,061, Nov. 14, 1939. A mixt. of Cu powder 82–86, Zn powder a trace to 10, Al powder a trace to 1.2, graphite a trace to 1.2, and CuO 3–10% by wt. in finely divided condition is molded in desired forms at 12000–24000 lb. per sq. in., heated 1–3 hrs. in an atm. of H, and impregnated with lubricating oil. Cf. *C. A.* **33**, 526[4].

Purifying cadmium sponge containing zinc. Wm. J.

O'Brien (to Glidden Co.). U. S. 2,178,763, Nov. 7. The wet freshly pptd. sponge is gradually added to molten NaOH contg. borax and an alkali metal or alk. earth metal chloride or fluoride and heated to about 350–450° to melt the Cd, and the heating is continued until all of the water has been removed as evidenced by disappearance of foaming, with final heating to about 550° and sepn. of the purified Cd.

Metals for electrical switch contacts. Lyall Zickrick (to General Elec. Co.). U. S. 2,178,508, Oct. 31. Contacts contg. at least 85% of Cu or Ag together with 0.2–5% of Se are resistant to welding action upon heavy current inrush. The contact metal may also contain Pb 0.8–10%.

Heat-treatment of metal filaments such as those for use in incandescent lamps. Wm. P. Zabel (to General Elec. Co.). U. S. 2,179,367, Nov. 7. Various details of app. and operation for use with a nonoxidizing atm.

Heat-treating camshafts. Joseph D. Judge (to Hamilton Foundry and Machine Co.). U. S. 2,178,281, Oct. 31. App. is described, and a method of heat-treating a camshaft of heat-treatable cast iron which comprises heating the camshaft above its crit. temp., then subjecting only the cam lifts to a rapid quenching operation through the crit. temp. and to a temp. of only a few hundred degrees F. by air and water for hardening the cam lifts, rotatably moving the camshaft through a small angle while the rapid quenching operation is effective, cooling the remaining portions of the camshaft at a slower rate to a point somewhat below the crit. temp., and then quenching the entire shaft by immersion.

Heat-treatment apparatus suitable for carburizing metal articles. Albert C. Dames (to Timken-Detroit Axle Co.). U. S. 2,179,073, Nov. 7. A container is used having an enlarged portion for holding a heat-treating compd. such as a carburizing compd. adjacent a desired portion only of an article such as a pinion gear placed in the container for heat-treatment.

Carburizing pot. Thomas A. Frischman and Curtis G. Shontz (to Eaton Mfg. Co.). U. S. 2,178,683, Nov. 7. Various details of an interchangeable chimney-type sheet-metal carburizing pot suitable for use in carburizing ring gears, etc.

Hardening ferrous metal surfaces such as those of cams. Charles W. Dake (to Campbell, Wyant and Cannon Foundry Co.). U. S. 2,178,201, Oct. 31. The high point and camming surfaces of cast ferrous cams are radiantly heated from opposite sides by elec. resistance heating and then cooled (various details of app. and operation being described).

Metal bearings such as those for shafts. Randolph L. Strickland (to Detroit Aluminum & Brass Corp.). U. S. 2,178,149, Oct. 31. Bearings are formed comprising an outer supporting layer of hard metal such as low-C steel, an intermediate layer of soft readily conformable particle absorbing bearing metal such as a babbitt metal, and an inner bearing layer of metal such as pure Cu which forms a very thin hard coating or skin and prevents cracking of the intermediate layer.

Sheet porous metal suitable for bearings. Wm. G. Calkins and Anthony J. Langhammer (to Chrysler Corp.). U. S. 2,178,529, Oct. 31. For the manuf. of sheet porous metal, a mixt. including powd. metals having different m. ps., such as one contg. Cu, Sn, Pb, boric acid and graphite, is continuously fed directly between opposed arcuate surfaces of a pair of pressure rolls to compress the mixt. uniformly from opposite sides into sheet-like briquet form, followed by heating to a sintering temp. in a furnace having a nonoxidizing atm. App. is described. Various examples are given.

Metallic compositions suitable for porous bearings. Child H. Wills (to Chrysler Corp.). U. S. 2,177,853, Oct. 31. A compressed and sintered product is formed of powd. metals such as Cu and Fe or Cu and Sn intermixed with about 0.25–1% of finely divided particles of vermiculite from which chemically combined moisture has been removed by heat treatment.

Etching metals. Edward A. Sikorski (to General Chemical Co.). U. S. 2,177,751, Oct. 31. An etching bath contg. HNO_3 is used with a small proportion of urea which serves to inhibit evolution of N oxide fumes.

Treating ferrous metals, as for steel production. James C. Vignos (to Ohio Ferro-Alloys Corp.). U. S. 2,179,167, Nov. 7. A bath of molten ferrous metal having a higher C content than desired in the metal to be produced is oxidized to reduce the C content to about 0.05–0.5%; a sep. bath of molten oxidizing slag contg. sufficient oxide to reduce appreciably the C content of the metal without eliminating an appreciable amt. of P is then formed and mixed with the molten metal to reduce the C content of the metal and effect a stronge volution of gas, with accompanying elimination of Mn, Si and the like from the metal and absorption by the slag, and the metal is then sepd. from the slag.

Steel resistant to alternate high and low temperatures. Russell Franks (to Electro Metallurgical Co. of Canada, Ltd.). Can. 385,093, Nov. 14, 1939. For devices that are to be alternately heated to about 400° and cooled to below about 0° there is used a ferritic alloy steel contg. Cr 4–10%, C in amts. not over about 0.15%, Si not over about 0.75%, Mo about 0.25–1.5% and Cb about 6–16 times the C content.

Steel resistant to oxidation. Russell Franks (to Electro Metallurgical Co. of Canada, Ltd.). Can. 385,092, Nov. 14, 1939. A steel resistant to oxidation at about 300–800° contains about 2–4% Cr, C in amts. not above about 0.3%, Ti, Cb, or mixts. of the two in such amts. that the sum of the Ti and 0.5 of the Cb is at least twice the C and does not exceed 4 times the C by more than about 0.75%, and about 0.2–1.5% of Mo or W.

Quenching steel and other alloys. Clarence W. Wilson (to Calif. Fruit Growers Exchange). U. S. 2,178,925, Nov. 7. Metals, after heating, as for effecting hardening of alloy steels, are quenched in an aq. medium contg. an alkali or NH_4 pectate and a surface-tension depressant such as a soap.

Removing the red color from heat-treated silicon steel. Donald C. Hilty. U. S. 2,178,791, Nov. 7. The steel is subjected to the action of a slightly acid soln. contg. SO_2 at a temp. not above 60° to remove the red color without substantial scale removal.

Seamless tubes from columbium-containing austenitic chromium-nickel alloy steel. Vere B. Browne (to Allegheny Ludlum Steel Corp.). U. S. 2,179,114, Nov. 7. Ingots of an alloy contg. Fe together with Cr about 16–18%, Ni about 8.5–11% (but with the ratio of Cr:Ni not over 2:1) and Cb about 0.3–1% are formed into billets (using a ferrous alloy which may contain "usual contaminants in common amts.") and the billets are pierced at a temp. of about 1150–1260° to form tubes which are then finished as desired.

Alloy steel. Marcus A. Grossman and Walther Mathesius (to Walther Mathesius and United States Steel Corp.). Can. 385,023, Nov. 7, 1939. A shallow-hardening alloy steel having a high degree of resilience and resistance to shock and fatigue contains C 0.85–0.95, Mn 0.20–0.50, Cr 0.20–0.50 and V 0.075–0.20%. Cf. *C. A.* **33**, 5799[4].

Alloy steel. Gustav A. Reinhardt. Can. 385,709, Dec. 19, 1939. An alloy steel that can be easily welded contains Ni, Cu not more than 50% of the amt. of Ni, C not in excess of 0.20%, Mn 0.35–0.70 and Si 0.10–0.25%.

Steel alloy. Russell Franks (to Electro Metallurgical Co. of Canada, Ltd.). Can. 385,091, Nov. 14, 1939. A ferritic steel alloy comprises Cr 2–30, C up to about 0.5, W, Mo or both 0.5–2.5, Cb in amt. at least 8 times and not over 1.5% plus 10 times the C content of the steel. It may be used for welding rods or for uniting adjacent edges of ferritic Cr steel articles contg. 2–30% Cr and up to 0.5% C.

Iron or steel alloy. Vsevolod N. Krivobok (to Rustless Iron and Steel Corp.). Can. 385,485, Dec. 5, 1939. An iron alloy or steel resistant to high temp. contains Cr 10–25, Ni 7–15, W 2–4, Mo 0.7–3, and C 0.003–0.2%. Can. 385,486, Dec. 5, 1939. An iron alloy or steel resistant to high temp. contains Cr 10–25, Ni 7–15, Co 0.5–3, Mo 0.5–4, Mn 0.5–4, and C 0.03–0.2%. Can. 385,487, Dec. 5, 1939. An iron alloy or steel resistant to high temp. contains Cr

10–25, Ni 7–15, Ti 0.30–1.5, W 2–4, and C 0.03–0.2%. Can. 385,488, Dec. 5, 1939. An iron alloy or steel resistant to high temp. contains Cr 10–25, Ni 7–15, Ti 0.30–1.5, V 0.30–1.5, W 2–4, and C 0.03–0.2%. Can. 385,514, Dec. 5, 1939. An austenitic Fe or steel resistant to high temp. contains Cr 10–25, Ni 7–15, Me 1–2.5, Cu 1–2.5, Mn 2–5, Al up to 3, and C 0.03–0.4%. Can. 385,515, Dec. 5, 1939. An austenitic iron or steel resistant to high temp. contains Cr 10–25, Ni 7–15, Mo 1–5, Cu 1–3, W 2–3, and C 0.03–0.4%. Can. 385,516, Dec. 5, 1939. An iron alloy or steel resistant to high temp. contains Cr 10–25, Ni 7–15, Mo 2.5–3.5, Cu 2.5–3.5, Al up to 3, and C 0.03–0.4%.

Hard alloy. Walther Dawihl and Karl Schröter (to Canadian General Electric Co., Ltd.). Can. 385,867, Dec. 26, 1939. An alloy, hardened by heating to 1000–1200° and quenching in oil, consists by wt. of 30–50% of a mixt. of Fe with Co or Ni and 2–10% Cr, the remainder being TiC and WC in a ratio of 1:2 to 1:0.5.

Copper alloys. Franz R. Hensel and Earl I. Larsen (to P. R. Mallory & Co., Inc.). U. S. 2,178,992, Nov. 7. Alloys which are suitable for elec. contacts or conductors are formed of Cu together with Si 0.1–0.8, Co 0.5–3, and Ag 0.05–2.5%.

Copper alloy. Horace W. Gillett and Russell W. Dayton (to Bunting Brass & Bronze Co.). Can. 384,540, Oct. 10, 1939. An alloy consists of an integrated mass of metallic particles similar to commercial machinings, composed of about Cu 80, Sn 10 and Pb 10%. The compressive strength is about 90,000 lbs./sq. in. for a d. of 70% and 150,000/sq. in. for a d. of 95%.

Wrought copper alloys. Michael G. Corson (to Union Carbide and Carbon Research Laboratories, Inc.). Can. 385,128, Nov. 14, 1939. Cu alloys contg. 0.05–0.5% Cr are cast, wrought and annealed. A fine-grain structure is preserved and grain growth inhibited by keeping the alloy below 850° during every step of the process subsequent to the casting step, the Cr being maintained in a uniformly distributed, finely pptd. form, and the mixt. of ppts. Cr being insufficient to raise materially the hardness of the alloy.

Copper alloys suitable for trolley line and telephone drop wires. Wm. B. Price (to P. R. Mallory & Co.). U. S. 2,177,745, Oct. 31. Alloys of high strength and elec. cond. are formed of Cu together with Cd 0.05–0.95 and Co 0.05–0.95%.

Ferrous alloy. Joseph V. Emmons (to Cleveland Twist Drill Co.). Can. 385,208, Nov. 21, 1939. A high-speed steel having a low sp. gr., hardening at about 2000–2300°F., tempering at about 1000–1150°F., at which temp. secondary hardness is developed, contains C about 0.30–1.60, Si about 0.55–3.00, Mo about 0.6–15, and W 10–30% of the amt. of Mo.

Lead alloy. Jesse O. Betterton, Albert A. Smith, Jr., and Albert J. Phillips (to American Smelting and Refining Co.). Can. 384,675, Oct. 17, 1939. A Pb alloy, used, e. g., for a battery grid, contains Mg 0.01–0.3%, Ca 0.03–3%, and a corrosion-resistant constituent selected from the group consisting of Cd, Cu, Hg and Sn. It is characterized by its hardness and high tensile strength.

Magnesium alloys. John A. Gann (to Dow Chemical Co.). U. S. 2,178,573, Nov. 7. Alloys of good corrosion resistance contain Mg together with Ag 0.3–12, Al 0.5–12, and Mn 0.1–0.5%. U. S. 2,178,574 relates to alloys of Mg with Cu 0.5–15 and Pb 0.5–20%. U. S. 2,178,575 relates to alloys of Mg with Cu 0.5–15, Pb 0.5–20, and Sn 0.5–12%. U. S. 2,178,576 relates to alloys of Mg with Cu 0.5–15, Pb 0.5–20 and Zn 0.5–10%. U. S. 2,178,577 relates to alloys of Mg with Cu 0.5–15, Pb 0.5–20, Sn 0.5–10, and Zn 0.5–10%. U. S. 2,178,578 relates to alloys of Mg with Ag 0.3–12, and Mn 0.1–2%. U. S. 2,178,579 relates to alloys of Mg with Ag 0.3–12, and Zn 0.5–8%. U. S. 2,178,580 relates to alloys of Mg with Ag 0.3–12, Mn 0.1–2, and Zn 0.5–8%. U. S. 2,178,581 relates to alloys of Mg with Ag 0.3–12, Al 0.5–12, and Zn 0.5–8%. U. S. 2,178,582 relates to alloys of Mg with Ag 0.3–12, Al 0.5–12, Mn 0.1–1, and Zn 0.5–8%.

Ferrotungsten and ferromolybdenum. V. N. Gusarov. Russ. 52,046, Oct. 31, 1937. A continuous process of fusion and removal of the alloy from the furnace is described.

Tungsten alloy. Colin J. Smithells (to General Electric Co., Ltd.). Can. 384,709, Oct. 17, 1939. An alloy having a d. of not less than 16, consisting of large grains of W cemented together by a Ni-Cu-W alloy, is prepd. by mixing intimately W 83–96, Ni 3.5–16.5, and Cu 0.5–13.5%, subjecting to pressure to form a self-supporting body and sintering at not in excess of 1450°.

Protective coatings on magnesium and its alloys. Martin Tosterud (to Magnesium Development Corp.). U. S. 2,178,977, Nov. 7. The surface is treated with an aq. soln. contg. an alkali metal dichromate and $ZnSO_4$ or $CdSO_4$, the soln. being maintained at an acidity not greater than that initially produced by the dichromate (suitably a pH of 4 to 5).

Coating ferrous metal bearing surfaces. Geo. I. Finch (to C. C. Wakefield & Co. Ltd.). U. S. 2,178,251, Oct. 31. A foundation layer and a subsequently applied similar layer, both of ferrous metal, as in bearings for shafts, are both provided with an amorphous, vitreous layer by mechanically disrupting the crystal lattices of the surface without attrition and without substantial alteration of configuration.

Corrosion-resistant steel. Russell Franks (to Electro Metallurgical Co. of Canada, Ltd.). Can. 385,465, Dec. 5, 1939. Articles resistant to sea water of pH less than 7 are composed of an alloy steel contg. Cr 6–24, Ni 8–14, Mo 2.5–4, Mn 2–4, C not more than 0.12, and Si not more than 0.5%. The Mo and Mn impart resistance to the corrosive action.

Arc-welding electrode. Orrin E. Andrus (to A. O. Smith Corp.). Can. 385,517, Dec. 5, 1939. An electrode comprises a C steel rod and H occluded in the steel, the H being at least that which may be occluded in a like steel rod in the absence of an inhibitor by electrolysis of an electrolytic bath when the rod constitutes an electrode where nascent H is liberated.

Electrodes for welding bronze. S. V. Ermilov and A. L. Shermushenko. Russ. 51,964, Oct. 31, 1937. Bronze electrodes are covered with a paste of 50–60% carborundum, 10–25% $BaCO_3$ or chalk and 15–25% Al.

Soldering aluminum. Frank O. Albertson and Gustav A. Olsen (to Albertson & Co., Inc.). Can. 384,388, Oct. 3, 1939. The Al surface is cleaned by abrasion, a $AgNO_3$ soln. is immediately applied to deposit Ag and protect the Al surface from the action of Hg, $CuSO_4$ soln. is applied to produce a layer of Cu, and a "tinning compd." comprising $HgCl_2$ and free Hg applied, the Cu and Ag coatings protecting the Al from the Hg. Fused solder is then applied by spraying.

Solder. L. J. Peeters and E. F. de Cock. Belg. 432,074, Feb. 28, 1939. The solder consists of Zn 83–90, Al 6–10, Cu 2–5, and Mg 0.15–0.25%.

Composition for use in soldering metals such as aluminum. John F. Howarth (50% to Albert I. Elias). U. S. 2,179,258, Nov. 7. NaF 1–3, NH_4Cl 12–25 and $ZnCl_2$ 74–87% are used together.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

A micromethod for the determination of the melting points (of organic substances). N. A. Izmailov and Z. P. Tkachenko. *Farm. Zhur.* 1938, No. 3, 29–33; *Khim. Referat. Zhur.* 2, No. 4, 85–6(1939).—A simple app. has been developed for the detn. of the m. ps. of org. substances between 50° and 300°. It consists of a nichrome

plate (50 × 2 × 0.08 mm.) with a crescent into which the substance under investigation is placed. A welded Cu-constantan thermocouple is attached to the plate by means of a mastic made out of gypsum and liquid glass. The plate is heated with an elec. current through a transformer (100–20 v.). The current strength is regulated by a rheostat. The thermoelec. strength is measured by a galvanometer whose results are recalcd. into degrees from a curve obtained from the detn. of the m. ps. of known substances. The Cu-constantan plate is fastened to a porcelain plate and placed under a microscope. To avoid heat losses through radiation the porcelain plate is covered with a cover glass with an opening over the crescent. The app. can also be used for thermal analyses of mixts.
W. R. Henn

Catalytic hydrogenation of binary and more complex mixtures. V. V. Ipatiev, Jr., M. I. Levina and A. I. Karlblom. *Uspekhi Khim.* **8**, 481–528(1939).—Review and discussion of data, chiefly on the olefin, acetylene and aromatic alcs., ethers and unsatd. acids on Pt, Pd, Ni and Mo_2S_3 catalysts at temps. from 0–400°.
F. H. Rathmann

Catalytic oxidation of olefinic hydrocarbons. W. L. Faith and M. S. Dendurent. *Refiner Natural Gasoline Mfr.* **18**, 393–6(1939).—2-Pentene, trimethylethylene, tech. amylene, heptene, and caprylene were oxidized with a large excess of air to give maleic acid. The vapors were passed over a V_2O_5 catalyst. At temps. of 350° to 500° conversions of 17 ± 5% may be obtained with amylene. Increasing the no. of C atoms increases the conversion. The space velocity has little effect. 11 references.
C. H. Brooks

Action of hexachloroethane on Grignard compounds. V. V. Korshak. *J. Gen. Chem.* (U. S. S. R.) **9**, 1153–4 (1939).—EtMgBr, PhMgBr, *p*-MeC_6H_4MgBr and α-$C_{10}H_7MgBr$, resp., were treated with C_2Cl_6 in ether, in the mol. ratio 8 : 1 and 1 : 1, resp. The results were in both cases the same, the reaction products being C_2H_6, C_6H_6, C_7H_8, $C_{10}H_8$, PhI_2, *p*,*p*′-bitolyl, α,α′-binaphthyl, C_2Cl_4, $C_2H_2Cl_4$ and C_2HCl_5. The reaction mechanism is discussed.
Gertrude Berend

Isomeric transformations of unsaturated halogen derivatives in the aliphatic series. II. Saponification of 1-chloro-3-methyl-1,2-butadiene. T. A. Favorskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 1237–42(1939); cf. *C. A.* **33**, 9281⁴.—ClCH:C CMe_2 on heating with H_2O and $CaCO_3$ to 80° is isomerized to CH:$CCMe_2Cl$ and ClCH. $CHCMe:CH_2$, with simultaneous formation of propyne, CH_2·CHCl, Me_2C·CHCHO and a dimeric compd. $C_{10}H_{14}Cl_2$, b_9 103–5°, d_4^{20} 1.0957.
Gertrude Berend

Molecular symmetry of isopropyl tri-*tert*-butyl tetrathioörthosilicate. H. A. Klasens and H. J. Backer. *Rec. trav. chim.* **58**, 941–7(1939)(in French).—Examn. of the structure of $Me_2CHSSi(SCMe_3)_3$ (I) showed a curious case of augmentation of symmetry. I was prepd. by the action of Me_2CHSNa on $ClSi(SCMe_3)_3$. The crystals of I are tetragonal and isomorphic with $Si(SCMe_3)_4$, $Ge(SCMe_3)_4$ and $Sn(SCMe_3)_4$. The unit cell, contg. 2 mols., is the same for the 4 compds. (a = 11.2, c = 9.3 A.). The space group is D_{2d} ($P\bar{4}2_1c$). Thus there is the symmetry S_4 for the central atom around which the 4 groups are arranged in tetrahedric fashion. The maintenance of a tetrahedral structure on introduction of a Me_2CHS group in lieu of a $SCMe_3$ group is attributed to a "statistical symmetry."
C. R. Addinall

Thermal decomposition of acetone. J. G. Davoud and C. N. Hinshelwood. *Nature* **144**, 909–10(1939).—Allen (*C. A.* **30**, 5181²) showed that there is an induction period in the thermal decompn. of Me_2CO at 462°, which indicates chain formation. His data are reinterpreted: the results he observed are probably due to effects of a secondary nature, possibly to polymerization of the ketene formed from the Me_2CO.
G. M. Petty

Hydrogen exchange reactions of esters in relation to reactivity in condensation reactions. Weldon G. Brown and Kenneth Eberly. *J. Am. Chem. Soc.* **62**, 113–15 (1940).—NaOEt-catalyzed H exchange reactions of various types of esters with EtOD have been studied. The data indicate the following order of acidity in esters of the type RCH_2CO_2Et: Ph > H > Me > Et > Pr > $C_{10}H_{21}$, $C_{16}H_{33}$ > cyclohexyl > iso-Pr. Vinylogic effects in unsatd. esters diminish with increasing length of the conjugated bond system and are highly dependent upon geometrical configuration. The failure of certain esters to undergo self-condensation under the usual conditions is ascribed to low acid strength, a conclusion supported by other observations. Cf. *C. A.* **32**, 116⁶,⁸, 117¹, 2521⁸.
A. B. Garrett

Diketene—a new industrial chemical. A. B. Boese, Jr. *Ind. Eng. Chem.* **32**, 16–22(1940).—Of the 4 structures proposed for diketene, that of vinylaceto-β-lactone H_2C:C.CH_2.CO.O (I) appears to account for the reactions of diketene most satisfactorily with but 1 exception, the formation of pyruvaldehyde on ozonolysis. The primary importance of I is based upon its exceptional chem. reactivity and consequently in the products which may be synthesized from it. Its most common reaction is the addn. of substances with an active H atom to yield compds. contg. the $AcCH_2C$:O group. Thus, I reacts with H_2O in the presence of catalysts to give $AcCH_2CO_2H$ which in turn decomp. to Me_2CO and CO_2. With alcs. in the presence of acid catalysts, esters of $AcCH_2CO_2H$ result. This method of synthesizing esters is superior to the classical Na condensation of AcOEt both academically and industrially. This reaction is a general type applicable to all aliphatic alcs., primary to tertiary, alc. ethers, chlorohydrins, substituted alcs., glycols, glycerol and phenols. I and primary aromatic mono- and polyamines react smoothly to yield the corresponding acetoacetylamines in a high degree of purity and with excellent yields. Similarly I also reacts with aq. solns. of NH_3, primary and secondary aliphatic amines. Thus, compds. such as $AcCH_2CONHPh$, $AcCH_2CONH_2$, and similar type substances can be readily prepd. With urea or disubstituted ureas, I reacts in an inert solvent, yielding 4-methyluracil or its homologs. $PhNHNH_2$ and I at room temp. yield the phenylhydrazone of $AcCH_2CONHNHPh$. At higher temps. 1-phenyl-3-methyl-5-pyrazolone is obtained in excellent yield. With aromatic hydrocarbons in the presence of $AlCl_3$ I gives rise to 1,3-diketones such as $BzCH_2Ac$. Halogens add to I to form γ-haloacetoacetyl halides and β-butyrolactone is formed when I is hydrogenated. I may be further polymerized by catalysts to yield a tetramer of ketene, dehydroacetic acid, which is also a very valuable reagent because of the large no. of com. derivs. which can be prepd. from it. Pyrolysis of I at 500–600° converts it to ketene which is a powerful acetylating agent. B. presents an excellent summary of the applicability of I, now available in com. quantities, in synthetic org. chemistry. 50 references are cited.
W. A. Cook

Aldehyde-nitroparaffin condensation. B. M. Vanderbilt and H. B. Hass. *Ind. Eng. Chem.* **32**, 34–8(1940).—By means of condensations of nitroethane, the nitropropanes and the nitrobutanes with HCHO, AcH and PrCHO, resp., a no. of new mono- and dihydric alcs. have been prepd. Typical acetates of these alcs. have also been synthesized. Reduction of these nitro alcs. by catalytic hydrogenation over Raney Ni yields the corresponding amino alcs. The following examples illustrate the technique employed in the prepn. of the mono- and dihydric nitro alcs. *5-Nitro-4-octanol:* 144 g. freshly distd. PrCHO (2 mols.) was added slowly to a well agitated soln. of 206 g. $BuNO_2$ (2 mols.), 100 cc. 95% EtOH and 4 cc. of 10 *N* NaOH in a 3-necked 500-cc. flask, with the reaction temp. maintained at 30–35° by external cooling. After ⅔ of the aldehyde was added, an addnl. 4 cc. of 10 *N* NaOH and 15 cc. H_2O were added, then the remainder of the aldehyde, and the soln. was allowed to stand for 4 days at 35–8°. The alkali is then neutralized with an equiv. quantity of HCl and the mixt. distd. under slightly reduced pressure. After removal of small quantities of unreacted aldehyde and $BuNO_2$, together with EtOH and higher-boiling impurities, the pressure was reduced to 5 mm. and 310 g. of 5-nitro-4-octanol (88.5% yield of reactants employed), a pale yellow liquid, was obtained. *2-Ethyl-2-*

nitro-1,3-propanediol: 64 g. of 37.5% formalin (0.8 mol. CH_2O) was added dropwise to a well-stirred mixt. of 35.6 g. of $PrNO_2$ (0.4 mol.) and 0.1 g. hydrated CaO in a 500-cc. 3-necked flask, with the temp. controlled at 30°. After ½ the formalin had been added, the contents of the flask became homogeneous. After addn. was complete the reaction mixt. was allowed to stand at room temp. for 43 hrs. CO_2 in very slight excess was added and the $CaCO_3$ removed on a Filter-Cel suction filter. The ppt. was washed with 5 cc. H_2O and the combined filtrate and washings evapd. at 200 mm., with the residue finally being heated to 90° at 20 mm. in a water bath. On cooling, the residue solidified. The yield was 59.4 g. 2-ethyl-2-nitro-1,3-propanediol of 98–99% purity. The phys. consts. of the nitro alcs. are tabulated in the following order, resp.: b_{10} (unless otherwise noted), d_4^{25} and n_D^{25}: *2-nitro-1-propanol*, 99°, 1.1841, 1.4379; *3-nitro-2-butanol* 92° 1.1296, 1.4420; *2-nitro-3-hexanol*, 108°, 1.0575, 1.4480; *2-nitro-1-butanol*, 105°, 1.3332, 1.4390; *3-nitro-2-pentanol*, 100°, 1.0818, 1.4419; *3-nitro-4-heptanol*, 115°, 1.0275, 1.4460; *2-methyl-2-nitro-1-propanol*, m. 89.5–90°; *3-methyl-3-nitro-2-butanol*, 90°, 1.1021, 1.4469; *2-methyl-2-nitro-3-hexanol*, 109°, 1.0405, 1.4499; *2-nitro-1-pentanol*, 117°, 1.0818, 1.4405; *3-nitro-2-hexanol*, 112°, 1.0487, 1.4438; *5-nitro-4-octanol*, 124°, 1.0394, 1.4463; *2-methyl-2-nitro-1-butanol*, 98°, 1.1047, 1.4468; *3-methyl-3-nitro-2-pentanol*, 100°, 1.1157, 1.4518; *3-methyl-3-nitro-4-heptanol*, 119°, 1.0281, 1.4532; *3-methyl-2-nitro-1-butanol*, 111°, 1.08886, 1.4430; *4-methyl-3-nitro-2-pentanol*, 96–8°, 1.0599, 1.4477; *2-methyl-3-nitro-4-heptanol*, 111°, 1.0140, 1.4485; *2-methyl-3-nitro-4-heptanol* (stereoisomer), 121° (m. 53°); *2-methyl-2-nitro-1,3-propanediol*, m. 149–50°; *2-ethyl-2-nitro-1,3-propanediol*, m. 56°; *2-nitro-2-propyl-1,3-propanediol*, m. 81°; *2-nitro-2-isopropyl-1,2-propanediol*, m. 87–8°. The solid nitroglycols were purified by crystn. from hot C_6H_6-BuOH and from H_2O. The two solid monohydric alcs. may be purified by vacuum distn. or crystn. Naphtha-C_6H_6 was employed for *2-methyl-2-nitro-1-propanol*, and naphtha for *2-methyl-3-nitro-4-heptanol*. All the liquid nitro alcs. were yellow when obtained by vacuum distn. They were aerated at 75–100° for 0.5 hr. to hasten polymerization of any unsatd. contaminants, washed with satd. $NaHSO_3$ to remove aldehydes and fractionated through a modified Podbielniak column at 10 mm. The solids are white cryst. products. All dihydric nitro alcs. and those monohydric nitro alcs. contg. less than 7 C atoms are quite sol. in H_2O. The former are insol. in nonbenzenoid hydrocarbons as are the monohydric nitro alcs. contg. less than 6 C atoms. All nitro alcs. are stable up to 100° but unstable at 150° or above and show chem. properties characteristic of aliphatic alcs. and nitroparaffins. The m. ps. of the amino alcs. are as follows: *2-amino-2-methyl-1,3-propanediol*, 108–9°; *2-amino-2-ethyl-1,3-propanediol*, 37.5–8.5°; *2-amino-2-propyl-1,3-propanediol*, 58°; and *2-amino-2-isopropyl-1,3-propanediol*, 74°. The dihydric amino alcs. are more stable thermally than are the corresponding nitro alcs. They are also stable toward strong alkalies at ordinary temps. and form salts with acids. The acetates of 4 nitro alcs. were prepd. by the standard procedure, employing Ac_2O. Their b. p. (10 mm.), d_4^{25} and n_D^{25} are as follows: *Acetate* of: *2-nitro-1-butanol*, 103°, 1.1164, 1.4287; *3-nitro-2-butanol*, 103°, 1.1089, 1.4281; *2-methyl-2-nitro-1-butanol*, 109°, 1.0932, 1.4350; *diacetate of 2-ethyl-2-nitro-1,3-propanediol*, 157°, 1.1718, 1.4444. Optical stereoisomers are possible for all monohydric nitro alcs. prepd., except *2-methyl-2-nitro-1-propanol*, since each contains 2 asym. C atoms and the mol. is also unsym. Thus 2 *d*- and 2 *l*-forms or 2 racemic isomers are predicted for each compd. From the properties of most of the nitro alcs. prepd. and contg. 2 asym. C atoms, it was apparent that only 1 of the *dl*-isomers was formed or that the 2 *dl*-forms had nearly identical b. ps. However, the 2 nitro alcs. derived. from Me_2CHNO_2 and AcH and PrCHO, resp., were exceptions. Both of these compds. distd. over a definite boiling range. The reaction mixt. from the latter reactant had a sufficiently wide boiling range so that 2 isomers were obtained by careful rectification; one such fraction solidified on cooling which greatly facilitated further sepn. The condensation product from 2 mols. Me_2CHNO_2 and 2 mols. PrCHO on careful fractionation at 10 mm. yielded 60% *2-methyl-3-nitro-4-heptanol*, b. 111°, and 40% distd. close to 121°. The former was further purified by refractionation and the latter by crystn. from C_6H_{12}. A portion of each yielded the corresponding amino alcs. with different phys. consts. The acetates of both fractions were likewise different substances although the analysis of both fractions showed both compds. were *2-methyl-3-nitro-4-heptanol*. The solid stereoisomeric alc. yielded an acetate b_{10} 122°; the acetate from the liquid stereoisomer b_{10} 128°. The nitro alcs. show promise as new solvents; the amino alcs. as intermediates in the synthesis of wetting agents, emulsifiers and detergents. The following U. S. pats. are based on this work: 2,132,352, 2,132,353 (*C. A.* **33**, 1801,2); 2,139,120, 2,139,121, 2,139,122, 2,139,123 and 2,139,124 (*C. A.* **33**, 21496,6,7). W. A. Cook

A color reaction of maleic anhydride, *p*-benzoquinone and their partially substituted derivatives. Alexander Schönberg and Abdel Fattah Aly Ismail. *Nature* **144**, 910(1939).—When a trace of maleic anhydride is added at room temp. to a colorless soln. of PPh_3 in $CHCl_3$ or C_6H_6 a permanent orange-red color is produced immediately. The same color is produced with mono- but not with disubstituted derivs. of maleic anhydride. The color is also shown by *p*-benzoquinone and those of its derivs. in which not all of the H atoms are substituted. E. D. Walter

Effect of acetone on the magnitude of the rotation of the plane of polarization of tartaric acid and the rate of its chemical reaction with ethyl alcohol. A. P. Trofimenko and S. F. Babak. *J. Phys. Chem.* (U. S. S. R.) **13**, 417–20(1939).—Addn. of acetone to an aq. soln. of tartaric acid and EtOH simultaneously linearly decreases the optical rotation and the soly. of tartaric acid and the rate of its esterification with the alc. F. H. Rathmann

The Diels-Alder [diene synthesis] reaction. Samuel Lamdan. *Rev. centro estud. farm. bioquím.* **29**, 70–88 (1939).—Discussion. L. E. Gilson

Structure of cellulose and other polymers related to simple sugars. W. N. Haworth. *Chemistry & Industry* 1939, 917–25.—A general discussion of the structure of cellulose, starch, glycogen, xylan and lichenin, based mainly on H.'s work with methylation. The cellulose aggregate consists of 100–200 glucose residues, as detd. by methylation expts. under different conditions. Analysis of the methylated cellulose showed that no end groups were present if the methylation was carried out in an atm. of N, although the size of the cellulose aggregate was apparently reduced. Methylation in air resulted in the production of end groups, indicating that the end groups exposed during methylation recombine in the presence of N and this recombination is inhibited in the presence of air. Cellulose is considered to be constructed of straight chains linked together by "cross-linkages" or valency bonds at intervals of 25–30 glucose units, thus forming closed loops. These cross-linkages or bonds are considered to be weaker than the bonds in the main chain. Some of these weaker bonds break upon methylation, the ends recombining completely in the presence of N and incompletely in air. S. I. A.

The hydrogen peroxide oxidation of cyclic compounds catalyzed by pervanadic acid. Wilhelm Treibs. *Angew. Chem.* **52**, 698–700(1939).—A summary with 44 references. Karl Kammermeyer

The polymerization of unsaturated hydrocarbons, particularly styrene and α-methylstyrene. H. M. Stanley *Chemistry & Industry* 1939, 1080–3.—A review with 15 references. Mark Plunguian

The stereoisomerism of organic dyes and its relation to the constitution and properties of reversible polymeric dyes. G. Scheibe. *Angew. Chem.* **52**, 631–7(1939).—A comprehensive treatise with data, diagrams and 34 references. Karl Kammermeyer

Structure of the dimeric forms of *o*-isopropenylphenols. Wilson Baker and D. M. Besly. *Nature* **144**, 865(1939).—The authors conclude that the dimeric forms of *o*-isopro-

penylphenols are derivs. of flavan. This structure adequately explains their properties. E. D. Walter

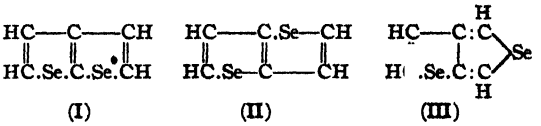
Organomercury compounds of vanillin. G. Rossi and M. Ragno. *Ann. chim. applicata* 29, 146–7(1939).—Hg(OAc)$_2$ in alc. soln. is added to an alc. soln. of vanillin, heating gently. A gelatinous mass forms, which gradually separates as a white powder. This is recrystd. from glacial HOAc. It is vanillin-mercury acetate, and no longer gives the common reactions for the Hg ion. Treated with H_2SO_4, the corresponding sulfate deriv. is formed. It is insol. in H_2O and other common solvents. A. W. C.

Synthesis of myristicin. Victor M. Trikojus and D. E. White. *Nature* 144, 1016(1939).—Allylation of pyrogallol 1-Me ether gave a mixt. of 2 liquid monoallyl ethers (I and II) which were sepd. by fractional distn. and characterized as their 3,5-dinitrobenzoates, m. 111° and 134°, resp. I rearranged on pyrolysis to give 3,4,5-MeO(HO)$_2$-$C_6H_2CH_2CH{:}CH_2$, and this on methylenation with CH_2I_2 gave 30% of myristicin, $b_{0.2}$ 95–7°. II on pyrolysis gave a mixt. which, on methylation and subsequent bromination, yielded mainly dibromomyristicin dibromide. E. D. Walter

Reaction capacity of the methyl group. IV. Derivatives of acetophenone and chalcone. Louis Chardonnens and Josef Venetz. *Helv. Chim. Acta* 22, 1278–86(1939); cf. *C. A.* 33, 8597[8].—It has been shown that Bz and SO_2-Ph groups in the *o*- and *p*-position render a Me group active in the presence of an addnl. NO_2 group. The similar activity of the Ac group has been investigated by a study of 4,3-Me(NO$_2$)C$_6$H$_3$Ac (I). Although PhAc does not react with *p*-ONC$_6$H$_4$NMe$_2$ (II) condensation takes place with 3- (III) and 4-O$_2$NC$_6$H$_4$Ac (IV), though not with the 2-isomer (V). A mixt. of 3.3 g. III, 3 g. II and 3 g. anhyd. Na_2CO_3 in 50 cc. alc. was refluxed for 32 hrs. The crude product (1.3 g.) could not be purified by crystn. but chromatographic analysis of 0.5 g. in benzene, elution of the central zone with acetone and recrystn. from acetone and alc. gave 0.2 g. of dark violet crystals of *3-nitrophenylglyoxal p-dimethylaminoanil*, $C_{16}H_{15}N_3O_3$, m. 170°. Similarly condensation of IV with II produced the corresponding *4-nitrophenylglyoxal anil*, m. 158–60°. Attempts to condense I with II gave a nonhomogeneous product with the appearance of an azomethine from which no definite compd. could be isolated. Thus it is not possible to show the reactional aptitude of the nuclear Me group in I by means of condensation with NO derivs. since the Me group of the Ac group apparently also enters into the reaction. I condenses with BzH in the presence of 10% NaOH to yield 90% of *2-nitro-4-cinnamoyltoluene* (VI), $C_{16}H_{13}NO_3$, m. 145–8°, identical with the product obtained in 70% yields by using piperidine as the condensing agent. A mixt. of 10.7 g. VI and 6 g. II in 100 cc. acetone and 150 cc. alc. was refluxed for 50 hrs. in the presence of 6 g. Na_2CO_3 and gave 9 g. of crude product, purified by chromatographic analysis to yield 38% of pure black crystals of *2-nitro-4-cinnamoylbenzaldehyde p-dimethylaminoanil* (VII), $C_{24}H_{21}N_3O_3$, m. about 210° (decompn.). Similarly the condensation of 1.4 g. VI with 0.7 g. BzH by heating for 3 hrs. at 190–200° in the presence of piperidine gave 16% of *2-nitro-1-styryl-4-cinnamoylbenzene*, $C_{23}H_{17}NO_3$, m. 164–5°. The reactional aptitude of the Me group of *2,6-dinitro-4-cinnamoyltoluene* (VIII) should be more marked than that of the corresponding Me group in VI. By refluxing with 60 cc. $SOCl_2$ for 2 hrs., 20 g. of 4,3,5-Me-$(NO_2)_2C_6H_2CO_2H$ was converted into 75% of the corresponding *chloride*, $C_8H_5ClN_2O_5$, m. 59–60°, and this was condensed with the Na deriv. of $AcCH_2CO_2Et$ and saponfd. with H_2SO_4 to give 28% of *4-methyl-3,5-dinitroacetophenone* (IX), $C_9H_8N_2O_6$, m. 66.7°; *phenylhydrazone*, m. 255° (decompn.). Condensation of IX with BzH in the presence of piperidine yielded 58% of the required VIII, $C_{16}H_{12}N_2O_6$, m. 206–7°. A mixt. of 1.12 g. IX and 0.5 g. BzH in the presence of piperidine was heated for 3 hrs. at 170°. The reaction mass was crystd. from a min. of boiling AcOH and recrystd. from benzene, yielding 0.3 g. of small yellow prisms of *2,6-dinitro-1-styryl-4-cinnamoylbenzene*, $C_{23}H_{16}N_2O_6$, m. 191°. The unsatisfactory results obtained in the condensation reactions with the chalcones VI and VIII are attributed to the decompn. which takes place at 200° in the presence of piperidine. C. R. Addinall

The production of benzoic acid from toluene in an oxidizing solution of potassium dichromate in sulfuric acid. Jaroslav Schneider. *Chem. Obzor* 14, 153–9, 177–83, 199–203(1939).—In the oxidation of toluene by $K_2Cr_2O_7$ and H_2SO_4, the temp. and the concn. of the acid were the governing factors: below 20° a concn. of 65% H_2SO_4 was not sufficient to begin the reaction; at 25° this concn. initiated the reaction. At 0° with 69% H_2SO_4 about 21% of the $K_2Cr_2O_7$ remained unreduced at the end of 6 hrs. With 80% H_2SO_4 the $K_2Cr_2O_7$ was reduced completely even at 0°. In the factory the gradual addn. of H_2SO_4 and the gradual elevation of the temp. from 80° to 95° gave a 72% yield in 30 hrs. with the concn. of H_2SO_4 at 50% and used in a 97% excess. The consumption of toluene was 130% of the theoretical with the largest losses occurring during the distn. The oxidation of BzOH to $CO_2 + H_2O$ occurred simultaneously with the oxidation of toluene to $PhCH_2OH$, BzH and BzOH. At lower temps. the oxidations were accompanied by condensations of toluene, $PhCH_2OH$ and BzH by the H_2SO_4 to form oils of the benzophenone type, $BzC_6H_4CO_2H$ and anthraquinone; about 5% of the toluene entered into these condensation products. In the presence of $Mn(OH)_2$ or $FeSO_4$ the yield was increased 10–19%: the catalysts shortened the reaction time, lowered the reaction temp., did not lower the min. concn. of 50% H_2SO_4 and interfered with the crystn. Frank Maresh

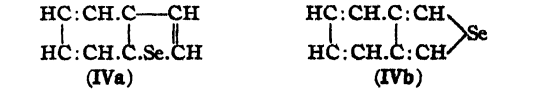
Conversion of sulfanilamide into *p*-hydroxyaminobenzenesulfonamide by ultraviolet irradiation. Lawrance E. Shinn, Edna R. Main and Ralph R. Mellon. *Proc. Soc. Exptl. Biol. Med.* 42, 736–8(1939); cf. *C. A.* 33, 8296[6].—Preliminary. L. E. Gilson



Difference in odor of *d*-, *l*- and *dl*-derivatives of amino- and bisaminomethylenecamphors. Bawa Kartar Singh and Awadh Behari Lal *Nature* 144, 910–11(1939).—The intensity of odor of the optically active forms of several new derivs. of amino- and bisaminomethylenecamphors was examd. In each series the *l*-form has the most intense odor, followed by the *dl*- and *d*-forms. E. D. Walter

Blue alkali salts of α-phylloquinone (vitamin K$_1$) and similar compounds. P. Karrer. *Helv. Chim. Acta* 22, 1146–9(1939).—On mixing with NaOEt, vitamin K$_1$ (I) and vitamin K$_2$ both give a blue color (*C. A.* 33, 5448[8]) which is not due to the presence of an impurity (*C. A.* 33, 5899[8]). This color reaction corresponds to those observed by Liebermann (*Ber.* 34, 1543 (1901)) on treating with NaOEt compds. contg. a reactive CH group obtained by acting on dihalonaphthoquinones with $CH_2(CO_2R)_2$, $PhCH_2CN$, $AcCH_2CO_2R$ and analogous compds. contg. an active CH_2 group. Electronic formulation of the equil. states of the anions of these compds. suggests a similar mesomeric formulation for the blue salts of I in which the CH_2 group attached to the naphthoquinone ring is activated by the neighboring ethylene linkage and analogous examples are cited in the blue salt of di-Me dihydrocrocetinate and the emerald-green salt of dihydromethylbixin (*C. A.* 27, 726). Other vitamin K-like compds. are in course of prepn. C. R. Addinall

Oxidative cleavage of the polyhydroxy side chains in the sugar condensation products of acetoacetic ester and of *o*-phenylenediamine. Sandor Müller and Ilona Varga. *Ber.* 72B, 1993–9(1939).—Antiketogenesis, the decrease or prevention of the formation of ketone bodies in fasting subjects or diabetics by the administration of glucose, makes it probable that in the organism sugars combine with the acetone bodies. A model of such compds. was prepd. by West (*C. A.* 22, 1140) from $AcCH_2CO_2Et$ and glucose as a cryst. substance, sensitive to acids, which, according to García Gonzáles (*C. A.* 29, 1088[4]), is Et 2-methyl-5-(*d-arabo*-tetrahydroxybutyl)furan-3-carboxylate (I). It takes up Br and reduces neutral $KMnO_4$ but is indifferent to Fehling soln. and is unchanged by $PhNHNH_2$. Its reactivity did not seem so pronounced as to warrant the conclusion that it can play any special role in antiketogenesis. West and co-workers (*C. A.* 30,



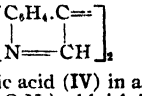
3787[8]), to be sure, have converted it into labile products with $HgSO_4$ and BzO_2H, showing its ready oxidizability, and García Gonzáles with $KMnO_4$ and alk. H_2O_2 obtained 2-methylfuran-3,5-dicarboxylic acid (II), but these oxidations shed practically no light on the mechanism of the reactions, especially whether they consist of a stepwise degradation or of a cleavage of the tetrahydroxybutyl side chain. M. and V. have now found that I can be oxidized under relatively mild conditions to well-defined products. The absorption of Br is itself an oxidation, for I becomes stable toward Br when the HO groups are acetylated. With somewhat more than 1 mol. $Pb(OAc)_4$ it gives in good yield an optically inactive *Et 2-methyl-5-formylfuran-3-carboxylate* (III), and *d*-glyceraldehyde and glycolaldehyde can also be detected. The side chain is therefore cleaved, chiefly between the trans 3,4-HO groups of the original sugar C chain. The presence of glycolaldehyde, even with a large excess of oxidizing agent, shows that cleavage between the 4,5-C atoms has also occurred, but the 3,4-cleavage must be the main reaction, for even 1 mol. $Pb(OAc)_4$ effects a complete transformation while the 4,5-cleavage causes a greater consumption of oxidizing agent since the resulting α-HO aldehyde (not isolated) is certainly further oxidized, with consumption of a 2nd mol. $Pb(OAc)_4$, to III more rapidly than is I itself. With excess of oxidizing agent there is also obtained glyoxal, whose formation is readily explained by further oxidation of the glyceraldehyde. The structure of III is established by its optical inactivity, its formation of a hydrazone (not an osazone) with $PhNHNH_2$, and its oxidation to II, m. 272–4°. The product (to be described later) of the hydrogenation of I and also West's "anhydroglucosecycloacetoacetic acid" give no furan derivs. with $Pb(OAc)_4$. The above oxidative cleavage is not limited to I. Its N isolog, Et 2-methyl-5-(*d-arabo*-tetrahydroxybutyl)pyrrole-3-carboxylate (IV) (García Gonzáles and Trujillo Torres, *C. A.* 29, 6889[7]), also undergoes the cleavage; the fate of the side chain was not followed but the good yield of *Et 2-methyl-5-formylpyrrole-3-carboxylate* (V) is considered proof of 3,4-cleavage. Similarly, 2-(*d-arabo*-tetrahydroxybutyl)quinoxaline, obtained from *o*-$C_6H_4(NH_2)_2$ and glucose, mannose or fructose, gives with $Pb(OAc)_4$ quinoxaline-2-aldehyde (VI). On the other hand, the benzimidazole derivs. obtained from *o*-$C_6H_4(NH_2)_2$ with galactose, arabinose, etc., which do not reduce Fehling soln., react differently with $Pb(OAc)_4$; no formylbenzimidazole is obtained. I (3.5 g. from 12 g. *d*-mannose, 5 g. powd. fused $ZnCl_2$, 6 cc. $AcCH_2CO_2Et$ and 6 cc. alc. heated on the water bath with stirring until a clear soln. is formed—about 10 min.), m. 147°, $[\alpha]_D^{25}$ −17.9° (MeOH). *d*-Fructose and *d*-galactose do not form I. Tetraacetate of I, m. 84°. *Tetrabenzoate* (72% from I with BzCl and pyridine), m. 107–10°, $[\alpha]_D^{25}$ −9.5° ($CHCl_3$). III, m. 56°, reduces Fehling soln. at room temp.; *$NaHSO_3$ compd.*, quite stable platelets which, however, become yellow after a time; *phenylhydrazone*, pale yellow, m. 100°; *semicarbasone*, m. 223°; *dimedon compd.*, almost colorless, m. 183–4°, forms yellow solns. IV (obtained in 10.8 g. yield according to García Gonzáles from 25 g. glucosamine-HCl and 25 cc. $AcCH_2CO_2Et$), m. 148–50°, $[\alpha]_D^{25}$ −24.1° (MeOH). V (2.2 g. from 5.4 g. IV), m. 132–3°, reduces Fehling soln. at room temp., is optically inactive; *semicarbazone*, m. 251°. VI (67% yield), m. 108°; phenylhydrazone, golden yellow, m. 231°; *semicarbazone*, m. 251°. With alk. H_2O_2 VI is oxidized to the acid, m. 212° (foaming). C. A. R.

Synthesis of condensed selenophenes by the action of acetylene on selenium. Sumio Umezawa. *Bull. Chem. Soc. Japan* 14, 363–73(1939).—Distn. of the tar (317 g.), obtained by the action of C_2H_2 on Se in an elec. oven, at atm. pressure to remove the selenophene (cf. *C. A.* 30, 5981[9]) gave an oily residue (150 g.) from which, after standing for a week or more in the dark, was isolated *isoselenophthene* (I) (21 g. or 6.7% of the original tar) as dark needles, m. 115–20°, which upon recrystn. from alc. formed rhombic crystals, m. 123–4.5°; the *picrate*, yellow, m. 163–5°, is readily decompd. by NH_4OH. I with Br_2 at low temp. gives *isotetrabromoselenophthene* m. 247.5° (cor.). I with concd. or fuming HNO_3 undergoes severe oxidation but in Ac_2O at −18° forms *isonitroselenophthene*, yellow, m. 108–9.5°, from alc. With concd. H_2SO_4 in Ac_2O at 70° I forms *isoselenophthenedisulfonic acid*, which is isolated as the *Ba salt* (+ $3H_2O$), forms a *K salt* (+ $1.5\ H_2O$), and with PCl_5 gives *isoselenophthenedisulfonyl chloride*, m. 234–6°. The remaining portion of the above oily residue (110 g.) was fractionally distd., giving the following 3 fractions: (1) b_{14} 93–100°, 30 g., 61.6% Se; (2) b_{14} 100–13°, 30 g., 63.2% Se; and (3) b_{14} 123–30°, 9 g., 42.2% Se. Fractions (1) and (2) consist essentially of selenophthene and a slight amt. of selenanaphthene and naphthalene. After removal of the last 2 by picrate formation, redistn. of fraction (2) gives 4.5 g. *cis-selenophthene* (II) as an almost colorless, highly refractive oil, b_{14} 90–3°, which gives the usual indophenol reactions and forms amorphous $Hg(OAc)_2$ and cryst. $HgCl_2$ complexes; II has the following phys. consts.: d_4^{25} 1.9354, n_D^{25} 1.6586, MR 44.55, calcd. for $C_6H_4Se_2$ (3 double bonds) 45.33; II and Br in CS_2 in the cold form *cis-tetrabromoselenophthene*, m. 271–2° (cor.). Steam distn. of the above oily residue, obtained after the sepn. of I, followed by fractional distn. gave a main fraction (30 g.), b_{11} 93–100°, from which the *picrate*, m. 154–5.5°, of *trans-selenophthene* (III), m. 51–51.5°, was obtained, which with Br forms the *trans-tetrabromoselenophthene*, m. 252.2–53° (cor.). The following structures of the above 3 forms were ascertained by dipole-moment measurements (cf. *C. A.* 33, 9064[3]):

(I) (II) (III)

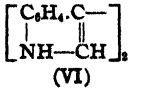
In order to ascertain the structure of selenanaphthene (IV), m. 50–1° (cf. Mazzo and Solazzo, *C. A.* 23, 2417; Komppa and Nyman, *C. A.* 28, 2710[4]), formed by the action of C_2H_2 on Se, between the 2 possibilities,

(IVa) (IVb)

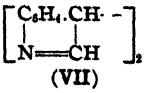


the synthesis of IV was accomplished in the following manner: diazotized *o*-$H_2NC_6H_4CH{:}CHCO_2H$ (10 g.) was treated with 7.8 g. KSeCN, giving 1.5 g. *o*-selenocyanocinnamic acid, m. 171–3°, which was converted with KOH to the corresponding selenolcinnamic acid which in turn was treated with $K_4Fe(CN)_6$, giving selenanaphthene, removed by steam distn., m. 50–1°, thus establishing its identity with the formula IVa. John F. Lontz

Transformations of indolyl methyl ketones into homologs of indole. II. Carlo Alberti. *Gazz. chim. ital.* 69, 568–83(1939); cf. *C. A.* 31, 8530[8].—Although indolyl Me ketones with the Ac group in β-position in the pyrrole nucleus are readily transformed by alk. alcoholates into alkylated homologs of indole (I), indolyl Me ketones with the Ac group in α-position do not undergo this transformation (cf. *loc. cit.*). β-Alkylindoles and α,β-dialkylindoles can thus be prepd., whereas direct alkylation of free I derivs. by alk. alcoholates (cf. Oddo and A., *C. A.* 27, 3933) gives only α,β-alkylated indoles. New expts. with α-acetylskatole (II) confirm the fact that homologs of I can be prepd. by means of alk. alcoholates, e. g., at high temps. and elevated pressures, II is decompd. completely, with partial elimination of its Ac group, and formation of amorphous *substances* with relatively low N contents and high mol. wts., probably degradation or condensation products of II. However, it is possible to transform α-acetylated indoles into dialkylated indoles by the action of NaOEt on the hydrazone or on the corresponding ketazine at elevated temps. II (1 g.), Na (1 g.) and anhyd. MeOH (15 cc.), heated in a Carius tube for 12 hrs. at 210–20° (a combustible gas is formed), the product (a yellow solid and red-yellow liquid) treated with water, almost neutralized with H_2SO_4, steam-distd. and the relatively small



quantity of distillate extd. with ether, yield from the ext. a yellowish, semisolid *substance*, which turns brown with picric acid in C_6H_6-benzine but gives no ppt. No skatole or 2-ethyl-3-methylindole was present in the distillate. The residue from the steam distn., dried over H_2SO_4, and purified by soln. in Et_2O, pptn. by petr. ether, and treatment with EtOH, yields an amorphous, ocher-yellow *substance* (III), m. 240–80°, insol. in dil. mineral acids and caustic alkalies. Mol.-wt. detns. gave values of 270–360; the % N was 6.50–6.90. No II was present in any of the products at any stage of purification. The filtrate from the residue of the steam distn. yields a trace of a yellowish *substance* (IV) and a larger quantity of AcOH. At 180–90° for 8–10 hrs., the yields of III, IV and AcOH are lower, and some unaltered II remains. At 150–160° there is no reaction. With EtOH instead of MeOH, the reaction is similar; the residue from the steam distn. yields a *substance* with properties like those of III and which may be the same. Attempts to prep. β-acetylindole hydrazone by treating β-acetylindole (V) in EtOH, dil. EtOH or AcOH with aq. $H_2NNH_2.HCl$ (1 1.5) and neutralizing with anhyd. K_2CO_3 were unsuccessful. However, V (1.6 g.), $H_2NNH_2.H_2O$ (VI) (0.75 g.) and EtOH (5 cc.), refluxed for 4 hrs., yield 85–90% of *β-acetylindolol ketazine*, $[C_6H_4.NH.CH:CCMe:N—]_2$ (VII), S-yellow, m. 280 2° (decompn.), reduces Fehling soln. and hot NH_3-$AgNO_3$, insol. in dil. mineral acids (but a lemon-yellow color is imparted to them); its solns. in concd. H_2SO_4 are lemon-yellow and in concd. HNO_3 are bright red. Likewise V (1.6 g.), VI (0.3 g.) and EtOH (5 cc.), refluxed for 3 hrs., yield 1.4 g. of VII. Under the same conditions as with V, β-acetyl-α-methylindole (VIII) (1.7 g.), VI (0.75 g.) and EtOH (5 cc.) yield an oil which did not solidify, even *in vacuo* over H_2SO_4; however, the reaction mixt., poured into water, extd. with Et_2O, the ext. dried by Na_2SO_4 and the ether-sol. product purified by EtOH, yields 20% of *β-acetyl-α-methylindole ketazine* $[C_6H_4.NH.CMe:CCMe\ N—]_2$ (IX), m. 263 5°; the mother liquor contains chiefly unaltered VIII. A higher yield is obtained by refluxing VIII (1.7 g.), VI (0.25 g.) and EtOH (10 cc.) for 5 hrs.; the yield is 0.5 g. of IX. It does not reduce Fehling soln. or NH_3-$AgNO_3$; but after treatment with hot dil. H_2SO_4 for a long time (decompn. to VI and VIII), IX does reduce these reagents. It is insol. in dil. mineral acids, but colors them lemon-yellow. Its solns. in concd. H_2SO_4 are lemon-yellow and in concd. HNO_3 are intense violet-red. II (1.7 g.) and VI (0.8 g.) in EtOH (5 cc.), refluxed for 4 hrs. and treated with EtOH, yield 1.6–1.8 g. of *α-acetylskatole hydrazone*, $C_6H_4.NH.C(CMe:NNH_2)\cdot CMe$ (X), straw-yellow, m. 142–4°, insol. in dil. mineral acids; concd. H_2SO_4 turns it orange-yellow, then lemon-yellow, and dissolves it; concd. HNO_3 turns it red-yellow and then dissolves it; it reduces hot Fehling soln. and NH_3-$AgNO_3$ (the latter reduction is more rapid if the mixt. is first boiled with H_2SO_4). II (1.7 g.) and VI (0.25 g.) in EtOH (5 cc.), refluxed for 4 hrs., yield 1.2 g. of *α-acetylskatole ketazine*, $[—N\cdot CMeC\ CMe.C_6H_4.NH]_2$ (XI), orange-yellow, m. 234 6°, does not reduce Fehling soln. or NH_3-$AgNO_3$. XI is present in the mother liquor from the crystn. of X, and it is formed by heating X above its m. p. Also X in ether (straw-yellow soln.) and 0.13 g. I in ether ppt. 0.08 g. of XI, and X (0.1 g.) in C_6H_6, heated gently with yellow HgO (0.12 g.), yields 0.07 g. of XI. VII (1 g.), Na (0.9 g.) and abs. EtOH (10 cc.), heated in a Carius tube for 8 hrs. at 180–200°, dild. with water, almost neutralized with H_2SO_4 and steam-distd., yield β-ethylindole (XII); the residue from the distn. (which can be purified by extn. with ether before steam distn.) is a *compd.* (XIII), contg. 24.12% N, probably either a β-ethylindolylhydrazine or a hydrazo deriv. of V, m. 120–1°, sol. in dil. HCl, dil. H_2SO_4, concd. H_2SO_4 and concd. HNO_3 (repptd. by caustic alkalies), does not form a chloroplatinate or chloroaurate, does not reduce Fehling soln. or NH_3-$AgNO_3$, is not oxidized in cold ether by I or in C_6H_6 by yellow HgO, is not attacked by boiling 20% aq. H_2SO_4; with NH_3-$AgNO_3$ it forms a *Ag deriv.*, sol. in mineral acids and in AcOH but hardly sol. in excess NH_4OH. *Picrate*, yellow. V (1 g.), 0.8 g. VI and 5 cc. EtOH, refluxed for 3 hrs., a soln. of 1.4 g. Na in 15 cc. abs. EtOH added, the mixt. heated in a Carius tube for 10 hrs. at 180–200°, dild. with water, almost neutralized by dil. H_2SO_4 and steam-distd., yield XII; the residue is essentially XIII. IX (1 g.), 0.8 g. Na and 10 cc. abs. EtOH, heated as was VII, yield 2-methyl-3-ethylindole (XIV) in the steam-distillate; the residue yields a *compd.* $C_{11}H_{15}N_3$ (XV), probably a β-ethyl-α-methylindolylhydrazine or more likely a hydrazo deriv. of β-acetyl-α-methylindole, m. 162–3°, basic, sol. in dil. HCl, dil. H_2SO_4 (repptd. by alkalies), concd. H_2SO_4 and concd. HNO_3, does not form a chloroplatinate or chloroaurate, does not reduce Fehling soln. or NH_3-$AgNO_3$, is not oxidized in Et_2O by I or in C_6H_6 by yellow HgO. *Picrate*, yellow. *Ag deriv.*, only slightly sol. in excess NH_4OH, sol. in acids, not attacked by boiling 20% H_2SO_4. V (1.7 g.), 1 g. VI and 10 cc. EtOH, refluxed for 4 hrs., a soln. of 1.4 g. Na in 15 cc. abs. EtOH added, heated in a Carius tube for 8 hrs. at 180–200°, and treated as before, yield XIV and XV. X (1.6 g.) and a mixt. of 1.4 g. Na and 20 cc. abs. EtOH, heated in a Carius tube for 10 hrs. at 170–80°, dild. with water, and steam-distd., yield *2-ethyl-3-methylindole* (XVI), lustrous, m. 66°; *picrate*, pomegranate-red, m. 150–1°; the residue from the steam distn. is an unidentified *compd.* (XVII), m. 118–19°, insol. in dil. mineral acids, sol. in concd. H_2SO_4 with brilliant violet color, sol. in concd. HNO_3 with brown color, does not form a chloroplatinate or chloroaurate, gives a red color with picric acid soln. but no ppt. X (from 1.7 g. of II) and NaOEt (from 1.4 g. of Na), heated in a Carius tube for 10 hrs. at 170–80°, dild. with water, nearly neutralized and steam-distd., yield 1.2 g. of XVI; the residue consists chiefly of a little XVII. XI and NaOEt, treated as above, yield XVI and a small quantity of a substance similar in properties to III. From the present work, in conjunction with earlier work, on the synthesis of homologs of I by means of alk. alcoholates, certain general conclusions are justified. The behavior of α-methylindole (XVIII) differs from that of I and skatole (XIX) with respect to alkylation by alcoholates, in strict analogy to their other reactions, e. g., the prepn. of acids by the action of CO_2 on magnesyl derivs., polymerization, etc. A Me group in the α-position in the tetrolic nucleus renders the imidic H of XVIII sufficiently mobile to make possible substitution with alkyl radicals and to obtain α,β-dialkylated homologs by transposition of the alkyl from the N to the β-C atom. On the contrary, the absence of a substituent in I and the presence of an alkyl group in the β-position in XIX do not render the imidic H sufficiently reactive to effect alkylation. A difference between XVIII on the 1 hand and I and XIX on the other is to be found in the behavior with dil. H_2SO_4, i. e., whereas VIII is hydrolyzed, V and II are not attacked. In contrast to the behavior of the free bases, it is necessary to distinguish, in the transformation of indolic ketones to homologs of I by alcoholates, between ketone derivs. with CO in the β-position (V and VIII) and those with CO in the α-position (II). In the 1st case the presence of a neg. β-Ac radical imparts to the imidic H sufficient mobility to make possible attack by alcoholates, even when the α-position is free, as in V, whereas I does not react. Derivs. with alkyl groups on the N are thus formed, with liberation of NaOH, which splits the Ac group; with subsequent transposition of the *N*-alkyl radical to the β-C atom, the final products are β-alkylated or α,β-dialkylated I derivs. On the contrary, in XIX, substitution of α-H by an Ac group does not render the mol. sufficiently reactive to be alkylated. All 3 indolic ketones are transformed in the same way by VI and NaOEt into homologs of I by substitution of Ac by alkyl groups having the same no. of C atoms. There are 3 possible general ways of obtaining homologs of I by means of alk. alcoholates: (1) direct alkylation of indoles when the latter are already α-alkylated; (2) alkylation of β-acyl-substituted indoles and



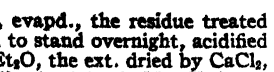
(3) reduction of indolic ketones through the corresponding hydrazones or ketazines for α- or β-acyl-substituted members. C. C. Davis

The pyrrole-indole group. II. 26. Dehydrogenation by means of sulfur. β,β′-Biindolyl from indole. Bernardo Oddo and Lina Raffa. *Gazz. chim. ital.* **69**, 562–8(1939); cf. *C. A.* **33**, 4239[7].—The paper is concerned with the reaction of indole (I) and S, which has been studied previously only by Madelung and Tencer (*C. A.* **9**, 2253, 2254). A mixt. of 2.5 g. I and 0.34 g. S, heated in a sealed tube for 48 hrs. at 115–25° (H_2S is evolved), the product washed with boiling petr. ether, dissolved in Me_2CO, aq. Na_2S added, dild. with water, the ppt. washed with water and ether-petr. ether, and purified from AcOEt, yields *β,β′-biindolyl* (II), lustrous, m. 286–7°, turns rose colored on long exposure to air, insol. in cold and hot dil. mineral acids and alkalies; its solns. in concd. H_2SO_4 are orange, by dil. with water turn bright red, and on further dil. turn colorless; its solns. in concd. HNO_3 are at first brown-red but soon turn ruby-red, and by addn. of water ppt. an unidentified dark red *compd.* which decomp. before fusion. At 0° aq. PhN_2Cl and alc. II give a brown-red liquid; aq. NaOAc added dropwise to this ppts. the *coupled compd.*, pomegranate-red, m. 162–5°. In further syntheses, the ratios of I to S were varied from 1 to 3 S atoms per I mol., with the conditions as before. In every case, II was the product, with yields which increased with increase in the S:I ratio. However, preliminary expts. indicate that at 190–200° sulfurated compds. are formed, with probable closing of the ring. Concd. aq. $NaNO_2$, added dropwise to II in cold glacial AcOH (the soln. turns intense brown-red with green reflection but with no pptn.), dild. with water, the ppt. purified from EtOAc and ligroin, the intensely orange mother liquor treated with $NaHCO_3$ and the addnl. ppt. purified as before, yields, after combination of the 2 ppts., not a NO deriv., but a *compd.* contg. 12.39% N ($C_{16}H_{10}N_2$ = 12.17%), dark orange, m. around 270° (decompn.), does not give a pos. Liebermann reaction, insol. in cold and hot concd. aq. alkalies. It is probably an oxidation product (III) of II as indicated also by the fact that if III in AcOH is treated with Zn + HCl,

(III) 

II is formed. II and picric acid (IV) in anhyd. PhMe ppt. the *picrate* $C_{16}H_{12}N_2(C_6H_3O_7N_3)_2$, bluish black with metallic reflection, m. 189° (with explosion), easily hydrolyzed. It is formed only in the presence of excess IV. A monopicrate could not be prepd. With aq. $AgNO_3$ (contg. NH_4OH), II in aq. Me_2CO ppts. the yellowish white *Ag deriv.*, sol. in excess NH_4OH, so unstable that it could not be analyzed. Attempts to prep. an iodate and perchlorate of II were unsuccessful, and the products were indefinite oxidation products of II. Thus II in Me_2CO or EtOH and aq. HIO_3 ppt. a *substance* which is at first greenish but turns black with liberation of I. Alc. II and $HClO_4$ give a soln. which slowly turns rose, then dark red after several days, with pptn. of a dark red *substance* which decomp. at a high temp. Gabriel, Gerhard and Wolter (*C. A* **17**, 3186) obtained from β,β′-biindolyl-α,α′-dicarboxylic acid a biindolyl which they designated α-biindolyl (V) to distinguish it from an another biindolyl, designated β-biindolyl, formed by heating V with HBr or HI and treating the product with alc. NH_3 (a protest is made against the widespread use of Greek letters, particularly in the German literature, to distinguish isomers while they are at the same time being used to indicate the positions of substituent groups). These isomers of G., G. and W. probably differed in the positions of the double bonds in the pyrrole nucleus, i. e., they might have been VI and VII,

(VI)



(VII)

but there was no indication of which was which. II, as prepd. by O. and R., had properties similar to those of the α-compd. of G., G. and W., and therefore the α-compd. of the latter was probably VI and their β-compd. was VII. To avoid confusion, the compd. of the VI structure should be termed β,β′-biindolyl and that of the VII structure *β,β′-biindolenyl*. C. C. Davis

Condensation products of *N*-aminocarbazole (biphenylenehydrazine) with fluorenone and its derivatives. M. Kh. Gluzman. *Trudy Khar'kov. gosudarst. Univ.* **3**, 73–9 (1938); *Khim. Referat. Zhur.* **2**, No. 4, 58(1939).—Condensation of *N*-aminocarbazole (I) with carbonyl compds. was investigated by Wieland (*C. A.* **7**, 596) and by Blom (*C. A.* **11**, 450). By condensing I with fluorenone (II) G. obtained fluorenone biphenylenehydrazone, $(C_6H_4)_2$-NN:C$(C_6H_4)_2$ (IV) and, correspondingly, he obtained 2-nitrofluorenone biphenylenehydrazone (V) by condensation of I with 2-nitrofluorenone (III). The method for the prepn. of *N*-nitrosocarbazole and of I was improved. For the prepn. of IV heat for 2–5 min. 1 g. of I and 1 g. of II in 10 cc. of alc. with a drop of concd. H_2SO_4. Light-red needles or flakes were obtained, m. 182–3° (rapid heating). For the prepn. of V heat for 30 min. 0.5 g. of I and 0.62 g. of III in 175 cc. of alc. with 3–4 drops of H_2SO_4. The V (0.8 g.) formed red needles from alc. The m. p. was not sharp. A change took place at 177° and melting at 198–203°. The soly. of IV and of V are given in a table. W. R. Henn

A new method of introduction of the nitrile group into compounds containing a methylene group with mobile hydrogen atoms. Carlo Musante. *Gazz. chim. ital.* **69**, 523–35(1939).—The expts. are based on the method of synthesis of isoxazoles described by Quilico and Fusco (*C. A.* **32**, 2117[4]) and involving the use of RC(:NOH)Cl compds, and had as their aim the prepn. of derivs. contg. the isoxazole nucleus carrying a CO in the 3-position. The reagent used in the earlier work, viz., PhC(:NOH)Cl, was replaced by EtOCOC(:NOH)Cl (I), which had already been used for synthesizing other heterocyclic compds. (cf. M., *C. A.* **32**, 9064[3]). Systematic expts. were started in which I was made to react with the Na salts of β-diketones, β-ketone esters, cyano ketones, cyanoacetic esters, etc., with a view to its condensation to isoxazole derivs., i. e., with compds. contg. CH_2 groups with active H atoms. It was not found possible to isolate in pure form the condensation products, and probably they are liquids or solids with very low m. ps. which cannot be distd. without decompn. even *in vacuo*, and which are obtained only in low yields. The present paper is not concerned with the isolation and purification of the condensation compds. but with their reactions with various reagents, with particular attention to reactions which prove that they are derivs. of isoxazole. $AcCH_2Ac$ (3 g.) and Na (0.69 g.) in abs. EtOH ppt. the Na salt (II); this, treated with alc. $EtO_2CC(:NOH)Cl$ (III) (4.55 g.) (the mixt. turns red-yellow, the II dissolves and NaCl is pptd.), allowed to stand for 24 hrs., filtered, evapd., water added, extd. with Et_2O, dried with $CaCl_2$, the residue (which could not be crystd.) treated with KOH in hot abs. EtOH, the pptd. K salt dissolved in water, washed with Et_2O, acidified with dil. H_2SO_4, allowed to stand for several hrs., and the ppt. purified by petr. ether, yields $NCCHAc_2$ (IV), m. 52–4° (cf. *Ber.* **31**, 2944 (1898)). It is sol. in aq. Na_2CO_3. The reaction between II and III was expected to be: I + II → $EtO_2CC(:N.O.CMe:CAc)$ + NaCl + H_2O, a reaction analogous to that between PhC(:NOH)Cl and II (cf. F., *C. A.* **33**, 8611[4]). But since the immediate product could not be isolated, the reaction mixt. was treated with alc. KOH in an attempt to form the corresponding acid. IV was the only product, however, and was formed by loss of CO_2 to form $HC(:N.O.CMe:CAc)$ and isomerization of the latter to IV. IV and $PhHNNH_2$ (V) (equimol. wts.) in AcOH, refluxed for 2 hrs. and dild. with water, yield 1-phenyl-3,5-dimethyl-4-cyanopyrazole, m. 90° (cf. Benary, *C. A.* **22**, 220). The condensation of II and III carried out as before, the filtered product evapd. *in vacuo*, water added, extd. with Et_2O,

the ext. washed with water, evapd., the residue treated with 10% aq. KOH, allowed to stand overnight, acidified with dil. H_2SO_4, extd. with Et_2O, the ext. dried by $CaCl_2$, evapd., the red-yellow oil dissolved in AcOH, V (same wt. as the oil) added, refluxed, dild. with water and the ppt. purified by dil. EtOH, yields *5-methylisoxazole-3,4-N-phenylmethylphthalazone*,

(VI), m. 178–9°, insol. in cold aq. Na_2CO_3 and in alk. hydroxides; sol. in boiling aq. KOH (yellow soln.). It is formed by elimination of 2 H_2O mols. from $HO_2CC(CMe{:}CAc)N(Ph)N{:}CMe$ and V, with cyclization. $BzCH_2Ac$ (4.55 g.), III (4.06 g.) and Na (0.6 g.) in EtOH, condensed by the same method as before, yield $BzCH(CN)Ac$ (VII), m. 74° (cf. Burns, *J. prakt. Chem.* [N. S.] **47**, 113 (1893)), sol. in aq. Na_2CO_3. In this condensation, alc. KOH can be replaced by dil. aq. KOH and the reaction carried out cold. VII and V form $MeC(CN){:}N.NPh.CPh{:}CCN$, m. 190° (cf. Burns, *loc. cit.*). VII and concd. HNO_3 (d. 152), boiled for several min., evapd. to a small vol., allowed to stand and the ppt. purified by water, yield an unidentified *compd.* contg. 8.43% N, m. approx. 70°. Bz_2CMe_2 (4.24 g.), III (2.87 g.) and Na (0.43 g.) in EtOH, condensed as before, yield $Bz(NC)CHBz$ m. 159–60° (cf. Claisen, *Ber.* **24**, 135 (1891)), sol. in aq. Na_2CO_3, gives a red color with alc. $FeCl_3$. $BzCH_2CO_2Et$ (7.68 g.), 5.5 g. III and 0.92 g. Na in EtOH, condensed as before, the initial oily product sapond. by alc. KOH, dissolved in water and acidified with dil. H_2SO_4, yield $NCCH_2COPh$. $EtO_2CC(CPh{:}N.O.CPh{:}CCO_2Et$ is formed first but could not be isolated, but with KOH formed unstable $KO_2CC(CPh{:}CCO_2K)N(O)C$, which lost CO_2 to form $HC(CPh{:}N.O.CPh{:}C)CO_2H$, which in turn isomerized to $Bz(NC)CHCO_2H$; this lost CO_2 to form $NCCH_2Bz$. $NCCH_2CO_2Et$ (VIII) (11.3 g.), 15.15 g. III and 2.3 g. Na in EtOH, condensed as before, allowed to stand for several hrs., evapd., water added, extd. with Et_2O, the red-yellow oil residue from the evapd. ext. (it decomposes when distd. *in vacuo*) dissolved in 10% aq. KOH (red soln.), allowed to stand for 12 hrs., clarified, acidified with H_2SO_4, the ppt. dissolved in aq. Na_2CO_3, repptd. by acid, and further purified by dil. EtOH, yield *carboethoxycyanoacetamide*, $H_2NCOCH(CN)CO_2Et$ (IX), lustrous, m. 162° (decompn. to an unidentified *compd.* with a higher m. p.); with alc. $FeCl_3$ it gives a blood-red color; in boiling concd. alk. hydroxides it evolves NH_3. *Ag salt*, $C_6H_7O_3N_2Ag$. When heated at 180° for a few min., IX forms an unidentified *compd.* contg. 20.55–20.95% N, does not m. below 270°. IX can be prepd. also from $H_2NCOCHNaCN$ and $ClCO_2Et$, which establishes its constitution. By the same condensation reaction used in prepg. IX, but substituting MeOH for EtOH, there is obtained *carbomethoxycyanoacetamide*, $H_2NCOCH(CN)CO_2Me$ (X), lustrous, m. 119° (decompn.); *in vacuo* over H_2SO_4 it loses its luster and changes its general appearance. At 180° it forms an unidentified *compd.*, which does not m. below 270°. With $FeCl_3$ it gives a red color. It does not react with Ac_2O nor with HNO_2. With hot aq. alk. hydroxides it evolves NH_3. With *p*-$O_2NC_6H_4N_2Cl$ its solns. in aq. NaOH turn intense red, and on acidification an unidentified *compd.*, $C_{11}H_9O_5N_5$, orange, m. 207–9°, is pptd. *Ag salt*, $C_5H_5O_2N_2Ag$. IX is formed by a reaction analogous to that between $PhC(:NOH)Cl$ and $NCCNaHCO_2Et$ (cf. Q. and F., *C. A.* **32**, 2117[4]), i. e., III + VIII → $EtO_2CC(CN){:}N.O.C(NH_2){:}CCO_2Et$ (XI) + NaCl. XI could not be isolated but was attacked by KOH with formation of 2 probable successive transitory products, viz., $HO_2CC(CN){:}N.O.C(NH_2){:}CCO_2Et$ and $HC(CN){:}N.O.C(NH_2){:}CCO_2Et$. The latter isomerizes to IX. In the formation of X, substitution of the Et group by the Me group takes place at the instant when VIII is mixed with NaOMe. Double decompn. takes place, with intermediate reversible formation of $NCCH_2C(OEt)(OMe)O$—, which can lose MeOH and regenerate the mesomeric anion $NCCH{:}C(OEt)O$— or lose EtOH with formation of the mesomeric anion $NCCH{:}C(OMe)O$— ⇄ $NCCHC(:O)OMe$ (XII), which belongs to $NCCH_2CO_2Me$. With excess MeOH, the equil. is displaced completely to formation of XII, which then reacts with III to form the condensation compd., $EtO_2CC(CN){:}N.O.C(NH_2){:}CCO_2Me$, which by sapon. forms X. The expts. show that the reaction between III and Na salts contg. CH_2 groups with active H atoms follows the same general course as benzalchloroxime and leads to isoxazole derivs. The presence of neg. groups (Ac, Bz, CO_2R, etc.) in the 4-position in the isoxazole nucleus renders the CO group in the 3-position particularly unstable so that, with the exception of the product from CH_2Ac_2 which is decarboxylated by alc. KOH, even cold aq. alkalies remove CO_2, with subsequent isomeriz[illegible] of the resulting isoxazole with a free 3-position to [illegible]-3-ketonic or β-diketonic nitrile. The use of III is a new "direct" method of introducing a CN group into a CH [illegible] with mobile H atoms, adjacent to a group which can [illegible] in ze with the =NOH group to an isoxazole. This is [illegible]ble in virtue of the facility with which isoxazole derivs. with neg. groups in the 4-position lose their CO groups in the 3-position by the action of alkalies, with opening of the nucleus.

C. C. Davis

New investigations of the isoxazole group. VII. Primary alcohols and aldehydes. Adolfo Quilico, Luigi Panizzi and C. Epifani. *Gazz. chim. ital.* **69**, 536–46 (1939); cf. *C. A.* **33**, 1728[8].—Although the reduction of phenylimido chlorides by $SnCl_2$ + HCl in Et_2O has been utilized in the prepn. of $O.CMe{:}C(CHO).CPh{:}N$ (cf. Q. and P., *C. A.* **32**, 7894[8]), this method is of no service in the prepn. of α- and γ-aldehydes, for the reduction continues beyond the stage of the Schiff base and the corresponding secondary amines of the aliphatic-aromatic type. Nor could α- and γ-aldehydes be prepd. by the use of nitriles according to the method of Stephen (*C. A.* **19**, 3261), for almost 100% yields of primary amines are obtained. Other investigators have encountered difficulties in other ways in attempts to synthesize heterocyclic aldehydes in general. α- and γ-Aldehyde derivs. of isoxazole should be of particular interest because of the positions of the CHO groups, and therefore it was decided to utilize the classic method of oxidation of the corresponding primary alcs., accessible from the amines. The expts. show that this synthesis can be carried out successfully. Aq. $NaNO_2$ (3.5 g.), added dropwise to boiling aq. $O.N{:}CMe.CH{:}CCH_2NH_2.HCl$ (6.0 g.) (the mixt. is maintained acidic by addns. of dil. HCl to prevent pith being formed), when N and other volatile compds. (including an irritating gas with the odor of PhNCO) are no longer evolved the mixt. filtered, satd. with $(NH_4)_2SO_4$, extd. with Et_2O, the dried ext. distd., and the yellow oily distillate (3.5 g.) fractionally distd. *in vacuo*, yields *γ-methyl-α-isoxazolecarbinol*, $O.N{:}CMe.CH{:}CCH_2OH$ (I), b_{25} 140°, slightly sweet odor, $d_4^{23.6}$ 1.1613, $n_D^{23.6}$ 1.48063. It can be oxidized by $K_2Cr_2O_7$ in H_2SO_4 to $O.N{:}CMe.CH{:}CCO_2H$, m. 210–11° (cf. Claisen, no reference). I in a dil. aq. alkali and BzCl yield the *benzoate*, $O.N{:}CMe.CH{:}CCH_2OBz$, m. 53.5–4.4°. I and *p*-$O_2NC_6H_4Cl$, warmed and treated with dil. NaOH, yield the *p-nitrobenzoate*, $O.N{:}CMe.CH{:}CCH_2OCOC_6H_4NO_2$-*p*, lemon-yellow, m. 82–3°. Aq. I (3.5 g.) and $K_2Cr_2O_7$ (5.5 g.), added slowly and alternately to

boiling H_2SO_4 (5 cc. of H_2SO_4 in 40 cc. of water), with continuous passing of steam during the addn. and then until the distillate no longer gives a reaction with *p*-$O_2NC_6H_4NHNH_2$ (II) in AcOH, the total distillate satd. with $(NH_4)_2SO_4$, extd. with ether (free of peroxides), the ext. dried, evapd., and the oil residue kept *in vacuo*, yield *γ-methyl-α-isoxazolealdehyde*, O.N:CMe.CH:CCHO (III), silky, m. 47–8°, sublimes *in vacuo* (30 mm. Hg) at 70–5°, penetrating aromatic odor, does not oxidize in air, reduces warm aq. NH_3-$AgNO_3$; with Piloty acid it gives a characteristic hydroxamic acid; it is sol. in warm 20% aq. KOH and on acidification O.N:CMe.CH:CCO$_2$H (cf. Claisen, no reference) is pptd.; the mother liquor, made alk., yields I. If, in the extn. of III, the ether contains peroxides, the oil which is extd. solidifies in a desiccator and, sublimed *in vacuo*, yields a *compd.* (IV) contg. 10.85–11.10% N, corresponding to $(C_5H_6O_2N)_2$ and perhaps a hydroperoxide, 2 III + H_2O_2. It has a penetrating odor of O_3. It m. 100–2° (decompn.). Its aq. solns. are acidic to Congo red, turn iodized starch paper intense blue and evolve O from acidic $KMnO_4$. III or IV and II in AcOH ppt. the *p-nitrophenylhydrazone*, O.N:CMe.CH:CCH:NNHC$_6$H$_4$NO$_2$-*p*, dark orange-yellow, m. 258–9° (decompn.). Aq. III or IV, $H_2NCH:NNHCONH_2$.HCl (V) and NaOAc ppt. the *semicarbazone*, O.N:CMe.CH:C-CH:NNHCONH$_2$, pearly luster, m. 225–6° (decompn.). Concd. aq. NH_2OH.HCl (contg. NaOAc and $NaHCO_3$) and III ppt., on standing, the *oxime*, O.N:CMe.CH:C-CH:NOH, m. 96.5–98°. III and excess CH_2N_2 in Et_2O evolve N and, by distn. of the ether and excess CH_2N_2 and steam-distn. of the residual oil, there is obtained *γ-methyl-α-acetylisoxazole*, O.N:CMe.CH:CAc, silky, m. 75–6°, characteristic odor. *p-Nitrophenylhydrazone*, dark yellow, m. 222–3°. *Semicarbazone*, lustrous, m. 203–4°. *Oxime*, m. 114–15°. Prepd. by the same method as I *α-methyl-γ-isoxazolecarbinol*, O.CMe:CH.C(CH$_2$OH):N (VI), b_{30} 134.5–5.5°, sweetish odor, $d_4^{13.8}$ 1.4628, $n_D^{13.8}$ 1.47967. Its chem. properties are similar to those of I. It is oxidized by CrO_3 to a 100% yield of O.CMe:CH.C-(CO$_2$H):N, already prepd. by Claisen (no reference). Alk. VI and BzCl yield the *benzoate*, m. 62–3°. *p-Nitrobenzoate*, silky, m. 92–3°. VI, oxidized by $K_2Cr_2O_7$ by the method used with I, yields *α-methyl-γ-isoxazolealdehyde* (VII), b_{30} 65–75°, becomes viscous but does not solidify when ice-cold, more penetrating odor than that of I, reduces warm NH_3-$AgNO_3$, gives the Angeli reaction with benzenesulfohydroxamic acid and the Cannizzaro reaction with aq. alkalies, does not oxidize in air, is oxidized by CrO_3 to O.N:C(CO$_2$H).CH:CMe, already known. *p-Nitrophenylhydrazone*, light orange, m. 228–9° (decompn.). *Semicarbazone*, pearly luster, m. 202–3° (decompn.). *Oxime*, m. 113–14°. VII and excess CH_2N_2 in Et_2O evolve N and, by evapn. and soln. in aq. V + NaOAc, yield the *semicarbazone*, O.N:C(CMe:NNHCONH$_2$).CH:CMe (VIII), m. 236°. O.N:C(CN).CH:CMe (cf. Q. and P., *C. A.* **33**, 1728[8]) (2.0 g.) in Et_2O, added dropwise to an ether soln. of MeMgI (from 0.67 g. of Mg and 4 g. of MeI) (the mixt. seps. into 2 layers), decompd. by ice and dil. H_2SO_4, the ether layer dried, distd., and the residual oil distd. *in vacuo*, yields γ-acetyl-α-methylisoxazole, b_{30} 75–80°. This identifies the constitution of VIII and therefore of VII. *Semicarbazone*, pearly luster, m. 237–8° (decompn.). I and VI are the 1st examples of primary alcs. in the isoxazole series. Likewise III and VII are the 1st primary alcs. in the same series to be described.

C. C. Davis

Syntheses of derivatives of isoxazole with fulminic acid. I. Adolfo Quilico, Giovanni Speroni and Ernesto Galeffi. *Gass. chim. ital.* **69**, 508–23(1939); cf. *C. A.* **34**, 4254.— In work published from 1929, Q. and his collaborators have shown that fuming HNO_3 (I) reacts with C_2H_2 (II) and Me_2CO (III) to form numerous products, some of which are isoxazoles, but the mechanism of the reactions was not established. It has now been found that all the isoxazoles formed from II and from III are of the HC:N.-O.CR:CH type, i. e., have the γ-position free and therefore contain the —CH:NO group, which in turn contains the characteristic group of fulminic acid (IV). This fact, in conjunction with the probability that IV is among the labile products of the reaction of I and II (cf. Wieland, *C. A.* **1**, 1270; **5**, 704), induced Q. and S. to investigate whether IV is an intermediate product of the formation of isoxazoles from II and III. The reaction would probably be: IV + HC:CR → [HON:CHC:CR] → HC:N.CR:CH, for other addn. reactions of IV are recorded in the literature. Since, however, the action of IV on the triple bond of II derivs. is not known, a systematic study was undertaken, the initial results of which with II are described in the present paper. It was difficult to find any exptl. conditions under which a compd. as easily polymerizable and unstable as IV would react with II. Bubbling of II into a suspension of Hg(ON:C)$_2$ (V) acidified by H_2SO_4 gave no definite results, but by conversion of V into NaON:C (VI) and treatment under the conditions described (which must be rigidly followed) satisfactory results were obtained. A VI soln. (prepd. from 40 g. of V in 125 cc. of water and 75 g. of Na-Hg contg. 8% Na), added dropwise to III already satd. with II and acidified with 4 cc. of 50% H_2SO_4 (the reaction mixt. treated with II throughout the addn. of VI), 50% H_2SO_4 also added dropwise simultaneously, with continuous agitation, and II passed for an extra 0.5 hr., yields a clear yellow soln. and a ppt. of V formed by decompn. of the complex compd. (VII) of Ehrenberg (*J. prakt. Chem.* **22**, 230 (1885)) which was in the soln. as a result of using an excess of V. With VII present, the yields are higher, so it probably acts as a catalyst. The reaction product, distd. (to remove III and water) until SO_2 is evolved, the distillate satd. with $(NH_4)_2SO_4$, extd. with Et_2O, the ext. dried by Na_2SO_4, evapd., the residue washed with 10% aq. NaOH, then with 10% H_2SO_4, dissolved in Et_2O, washed with water, dried again, evapd. and fractionally distd., yields *α-isopropenylisoxazole*, $H_2C:CMeC:CH.-CH:N.O$ (VIII) (6 g. from 5 syntheses), b. 151.5–2°, highly refractive, characteristic pleasant odor, $d_4^{13.8}$ 1.0126, $n_D^{13.8}$ 1.48054. Its soly. in water is 1 part in 120 parts at room temp. It is resistant to hot aq. alkalies and alk. alcoholates, and only by prolonged heating is it decompd. with evolution of NH_3. It is sol. in cold concd. HNO_3 (repptd. by water). Its solns. in concd. H_2SO_4 are light brown. Contrary to ethylene derivs. of the C_4H_6 series, it does not polymerize. It decolorizes Br water and reduces cold acidic $KMnO_4$ rapidly. VIII (1 cc.) and Br (0.55 g.) in CS_2, allowed to stand for several hrs., evapd., the residue washed with aq. $NaHCO_3$ and water, dried by Na_2SO_4, and fractionated *in vacuo*, yield the *di-Br deriv.*, $C_5H_3NOCBrMeCH_2Br$, highly refractive, characteristic mint-like odor, b_{12} 130–5°, does not solidify in a freezing mixt. VIII and $K_2Cr_2O_7$ in 10% H_2SO_4, refluxed for 7–8 hrs. (the liquid turns green), satd. with $(NH_4)_2SO_4$, and extd. with Et_2O, yields almost 100% of *α-isoxazole carboxylic acid* (IX), m. 149° (cf. Q. and Freri, *C. A.* **24**, 3484). Aq. $KMnO_4$ (8.8 g.), added dropwise to an ice-cold suspension of VIII (2.5 g.) in 10% H_2SO_4, most of the MnO_2 removed by (CO$_2$H)$_2$, filtered, steam-distd., the distillate satd. with $(NH_4)_2SO_4$, extd. by Et_2O, the ext. dried, evapd., the residue fractionally distd. *in vacuo*, and the distillate, which b_{37} 57–70°, redistd. at atm. pressure, yields 1.2 g. of *α-acetylisoxazole* (X). X

(1.5 g.) in anhyd. Et_2O, added dropwise to ice-cold Grignard reagent (prepd. from 0.68 g. of Mg and 4 g. of MeI in a current of H), allowed to stand for several hrs., the ppt. decompd. by ice-cold 5% H_2SO_4, satd. with $(NH_4)_2SO_4$, extd. by Et_2O, and the residue from the ext. distd. *in vacuo*, yields *α-isoxazoledimethylcarbinol* (**XI**), pale yellow, odorless oil, b_{15} 90–100°. When heated with P_2O_5, dild. with water and steam-distd., it is dehydrated to **VIII**. The mechanism of formation of **VIII** is clear from a consideration of the facility with which **II** derivs. and their hydration products condense to long-chain compds. **VIII** is formed from 1 mol. each of **II**, **III** and **IV**. **III** is not merely the solvent but takes part in the reaction. It is suggested that the initial reaction is: **II** + **III** → HC:CC(OH)Me_2 (**XII**), a reaction already known under other conditions. **XII** and **IV** then react thus: **IV** + **XII** $\xrightarrow{-H_2O}$ → [HON:CHC:CC(OH)Me_2] → **XI** ⟶ **VIII**. The ease with which **XI** is dehydrated to **VIII** makes it probable that **XI** rather than **VIII** is the chief product of the reaction of **II**, **III** and **IV**. This reaction is of great interest in that it offers a new method of synthesis of isoxazole derivs. with free γ-position. It should be possible to find conditions, in the absence of **III**, to synthesize isoxazole (**XIII**) itself; thus: =C:NOH + **II** → **XIII**, a reaction which would be analogous to the known one: $H_2CN{:}N$ + **II** → HN.N:CH.CH:CH. The analogy in these reactions between compds. with the —C:C— group and those with the —$COCH_2$— group (which is derived from the former by addn. of H_2O) suggests that β-ketone esters, β-diketones, $NCCH_2CO_2Et$, etc., may react with **IV** thus: =C.NO + $RCOCH_2COR$ → [HON:CH.C(COR).C(OH)R] → O.N:CH.C(COR):CR + H_2O. In this case there would be a parallelism between the synthesis of isoxazoles from **IV** and that from HClC:NOH (cf. Q. and Fusco, *C. A.* **32**, 2117[4]), since **IV** can be regarded as formed thus: HClC.NOH → C:NOH + HCl. Also the synthesis by **IV** explains the formation of isoxazole derivs. in the reaction between **I** and **II**. **IX** is probably formed as follows.

=C:NOH + 2 **II** → [HON:CHC:CCH.CH_2] → O.N

IX, or else: =C:NOH + **II** + **III**

→ [HON:CHC:CCH(OH)Me] → O.N:CH.CH:CC(OH)HMe $\xrightarrow{HNO_2}$ **X** $\xrightarrow{HNO_2}$ **IX**. The mol. refraction of **VIII** is higher than the refractions of dimethyl- and trimethylisoxazole, because of the exaltation by the double bond in the side chain. Mol. refraction data on isoxazoles are scanty, so the mol. refractions of HC:CMe.O.N:CCH_2OH and O.N:CMe.CH:CCH_2OH (to be described in a forthcoming paper by Q. and Panizzi), HC:N.O.CMe.CBr, HC:N.O.CMe:CCl, MeC:N.O.CH:CBr, MeC:N.O.CMe:CCl and MeC.N.O.CMe:CBr (cf. Q. and Justoni, *C. A.* **32**, 7455[1]) and O.N:CH.CMe:CMe and O.N.CMe:CMe:CH (cf. Justoni, *Rend. ist. lombardo sci.* **71**, No. 2 (1938)) were detd. The data are in harmony with previous data. The Br derivs. show smaller depressions than do the Cl derivs. A comparison of the values of the α-substituted derivs. with those of γ-substituted derivs. shows an interesting regularity, which may be of service in structural problems. In all cases the attenuating effect on the depression of the mol. refraction is greater when the substituent is in the α-position than when it is in the γ-position. C. C. Davis

The transformation of γ-isoxazolecarboxylic acids into derivatives of pyrazole. I. Sigismondo Cusmano. *Gass. chim. ital.* **69**, 594–601(1939).—Although it might be expected that γ-isoxazolecarboxylic acids would in general decomp. when heated, thus: RC:CH.C(CO_2H):N.O → RC:CH.CH:N.O → $RCOCH_2CN$, Claisen found (*Ber.* **24**, 3909(1891)) that no such cyano ketonic compds. are formed, but rather polymers or resins, and that only PhC:CH.C(CO_2H):N.O (**I**) behaved in this way. Furthermore Quilico and Freri (*C. A.* **24**, 3484) found that $HO_2CC.CH.CH{:}N.O$ did not decomp. when heated to HC CH.CH:N.O or thence to the successive product, $NCCH_2CHO$, but to pitchy or carbonaceous substances, even *in vacuo*. Also the temp. plays a part in the results, for some acids are decarboxylated at different temps. from others and the higher temps. necessary for some govern in turn the subsequent reactions. However, even if it has so far been impossible to find conditions under which isoxazolecarboxylic acids form cyano ketonic compds. (except with I), it should be possible to obtain definite and relatively simple compds. by heating an isoxazolecarboxylic acid in the presence of a compd. capable of combining with the CO and CN radicals at the instant of their formation; in this way the reaction should result in definite compds. rather than intractable polymers. $PhHNNH_2$ (**II**) was chosen as the reagent and, although various products were to be expected, the acidic nature of the isoxazolecarboxylic acids made the formation of stable salts of **I** seem likely, while it seemed possible, by proper control of heat, to obtain phenylhydrazones or definite compds. with other nuclei. Since **I** is the only acid of this series which does not decomp. too profoundly by heating, it was chosen for the 1st expt. **I** (1 g.) and 3 g. **II**, heated cautiously over a flame until gas (chiefly CO_2 and water) is no longer evolved, dild. with water, acidified with AcOH, poured into water, allowed to stand for 3–4 hrs., and the ppt. purified by C_6H_6, yield 80% of PhC·N.NPh.C(NH_2):CH (**III**), contains C_6H_6 of crystn., which it loses on exposure to air, m. 129–30°, is not altered by prolonged treatment with boiling dil. HCl in EtOH or with boiling aq.-alc. NaOH, sol. in dil. mineral acids (repptd. by NH_4OH). It has been prepd. by other reactions by Mouneu and Lazennec (*C. A.* **1**, 858), Seidel (*J. prakt. Chem.* **58**, 137 (1898)) and Justoni (*C. A.* **32**, 6243[2]), and the compd. prepd. by the method of S. was found to be identical with that obtained in the present work. The reaction of **I** and **II** probably involves the initial pyrogenic decompn. of **I** to PhC·CH.CH:N O, isomerization of the latter to Bz-CH_2CN; the latter with **II** forms the phenylhydrazone, PhC(CH_2CN):NNHPh, which isomerizes to **VI** (see below). Mono-Ac deriv., m. 153° (cf. 149° to 152.5° in the literature). **III** and BzH, heated over a flame for several min. (water is evolved), yield after dilu. with EtOH and standing, the *benzal deriv.*, PhC:N.NPh.C(N:CHPh):CH, yellow, m. 122°. Aq. $NaNO_2$ (1 g.) added dropwise to **III** (3 g.) in cold AcOH, allowed to stand for 1 hr., the products completely pptd. by addn. of water and the ppt. extd. by hot 5% aq. alc. NaOH, leaves a residue of a *compd.*, $C_{30}H_{23}N_7$ (**IV**), yellow, m. 217°, neutral, insol. in concd. mineral acids, except in concd. H_2SO_4 (repptd. by diln.). The alk. ext., acidified by dil. AcOH and the ppt. purified by C_6H_6, yields a *compd.*, $C_{15}H_{11}N_3{:}NOH$ (**V**), dark red, m. 207, acidic; its C_6H_6 solns. are dark green. In this reaction of **III**, it probably reacts in a tautomeric form, PhC:N.NPh.C(:NH).CH_3 (**VI**). **V** has the probable structure PhC:N.NPh.C(:NH).C:NOH, and is therefore a deriv. of **VI** rather than of **III**. This is supported by the acid hydrolysis of **V**, i. e., when refluxed in EtOH with concd. HCl for 3 hrs., it yields a *ketone*,

PhC(:N.NPh.CO.C:NOH, orange-yellow, m. 200°, acidic. On the contrary, IV is probably formed from the III structure and is an azoimino compd., PhN.N:CPh.CH:CN:NNHC:CH.CPh:N.NPh. Seidel prepd. a presumably identical compd., but regarded it as PhN.N:CPh.CH_2.C(:N.N:C.C(.NH).NPh.N:CPh (cf. *J. prakt. Chem.* **58**, 137(1898)). However, it does not give an Ac deriv. nor is it basic, so that the constitution assigned to it by C. is more reasonable. II. *Ibid.* 621 8.—As with other isoxazolecarboxylic acids, *p*-$O_2NC_6H_4C$(:CH.C(CO_2H):N.O (I) does not give a cyano ketone when decompd. alone pyrogenically; therefore it was of interest to study its behavior when heated with $PhHNNH_2$ (II), as was PhC(:CH.C(CO_2H):N.O (III) in the preceding expts. The same procedure was followed as in the reaction with III. Under these conditions there is obtained almost 100% of *1-phenyl-3-p-nitrophenylpyrazolone-5-imine*, *p*-$O_2NC_6H_4$-C(:N.NPh.C(.NH).CH_2 (IV), lustrous golden yellow, crystallizes with C_6H_6, which it loses on exposure to air, m. 185°, sol. in warm dil. acids (repptd. by NH_4OH), remains unaltered after several hrs. in boiling HCl (1:5) and 10% aq.-alc. NaOH, does not react with NH_2OH or semicarbazide. *Mono-Ac deriv.*, yellow, m. 210°, insol. in dil. mineral acids. *Benzal deriv.* (V), yellow, m. 175°, insol. in dil. mineral acids. Aq. $NaNO_2$ (0.75 g.), added dropwise to IV (3 g.) in cold dil. AcOH, allowed to stand for 0.5 hr., water added, a suspension of the ppt. in 5% aq.-alc. KOH heated almost to boiling, and filtered, leaves a residue which, purified by xylene, yields a *compd.*, $C_{30}H_{21}O_4N_9$, yellow, m. 310°, insol. in concd. and dil. mineral acids, sol. in concd. H_2SO_4 (repptd. by diln.), does not give an Ac deriv., i. e., its properties are similar to those of the compd. $C_{30}H_{23}N_{17}$ obtained in the earlier expts. (cf. preceding abstr.). The alk. soln., acidified by dil. AcOH, ppts. *1-phenyl-3-p-nitrophenyl-4-oximinopyrazolone-5-imine*, *p*-$O_2NC_6H_4C$:N.NPh.C(:NH).C:NOH (V), greenish yellow, decomp. approx. 290°, has both acidic and basic properties, sol. in cold. concd. HCl (repptd. by diln. with water); hot concd. mineral acids transform it into a *compd.*, $C_{15}H_{16}O_4N_4$, orange-red, m. 209°, acidic. VI and concd. HCl refluxed for 4 hrs., dild. with water, and the ppt. purified by aq. Me_2CO, yield a *ketonic compd.* *p*-$O_2NC_6H_4C$:N.NPh.CO.C:NOH (VII), orange-yellow, m. 209°, insol. in aq. mineral acids, sol. in aq.-alc. NaOH (pptd. by acidification.). A mixt. of IV, alc. AcOH and powd. Zn, allowed to stand for 15 min., refluxed, filtered, the filtrate made alk. by NH_4OH, extd. with Et_2O, the ext. washed and dried by Na_2CO_3, evapd., the residue dissolved in boiling AcOH, filtered and allowed to stand, yields *1-phenyl-3-p-aminophenylpyrazolone-5-imine*, lustrous, m. 110°; when treated with boiling Ac_2O it yields the *di-Ac deriv.* $C_{15}H_{12}N_4Ac_2$, lustrous, m. 235°; when treated in aq. HCl with hot aq. picric acid it forms the *picrate*, $C_{15}H_{14}N_4.2C_6H_3O_7N_3$, yellow, m. 220° (to a brown liquid). The behavior of IV with BzH and with HNO_2 is explained by assuming that like other RC:N.NR.C(:NH).CH_2 compds., it can isomerize to a tautomeric form: *p*-$O_2NC_6H_4C$:N.NPh.C(NH_2):CH (VIII). VI is formed from the IV form, since acids remove its imine group, with formation of VII. The formation of V with no basic properties of its parent compd. indicates that it is formed from the VIII form. The properties of the unidentified $C_{30}H_{21}O_4N_9$ indicate that it too is formed from VIII, and probably it is an *azoimino deriv.* of the constitution: PhN.N:C($C_6H_4NO_2$-*p*).CH:CN:NNHC:CH.C($C_6H_4NO_2$-*p*):N.NPh. IV is probably formed through a series of transformations, thus: I $\xrightarrow{-CO_2}$ *p*-$O_2NC_6H_4C$:CH.CH:N.O $\xrightarrow{+\ PhNHNH_2}$ *p*-$O_2NC_6H_4COCH_2CN$ → *p*-$O_2NC_6H_4C$(:NNHPh)CH_2CN → IV, and it is significant that, whereas decarboxylation of I leads to resinous products, fusion of I with $PhHNNH_2$ gives 100% of IV. C. C. D.

The salts of mercaptobenzimidazole. M. Kuraš. *Collection Czech. Chem. Commun.* **11**, 313–20(1939).—See *C. A.* **33**, 7298[9]. H. Gamc

Simple hydroxychromans and hydroxycoumarans. P. Karrer, R. Escher and H. Rentschler. *Helv. Chim. Acta* **22**, 1287–91(1939).— The supposition that the condensation of trimethylhydroquinone (I) with MeCH:$CHCH_2Br$ to 2,5,7,8-tetramethyl-6-hydroxychroman (II) (*C. A.* **33**, 3793[2]) also yields the isomeric *2-ethyl-4,6,7-trimethyl-5-hydroxycoumaran* (III) has been established by isolation of III from the condensation mother liquors and its identification with a product prepd. by the condensation of trimethylbenzoquinone (IV) with $EtCOCH_2CO_2Et$ (V) according to the procedure of Smith and McMullen (*C. A.* **30**, 3797[9]). A mixt. of 6.5 cc. V in a suspension of 1 g. Na in 80 cc. anhyd. benzene was refluxed and the cooled soln. was treated with 4.8 g. IV. After standing for 3 weeks, dil. HCl was added, the benzene layer was sepd., dried and evapd. Steam distn. of the residue and crystn. of the distillate from alc. in the presence of charcoal gave 1.4 g. of *2-ethyl-4,6,7-trimethyl-5-hydroxycoumarone*, $C_{13}H_{16}O_2$, m. 108°, catalytically reduced in AcOH in the presence of PdO_2 at 40–50° to colorless needles of III, $C_{13}H_{18}O_2$, m. 120° (from dil. alc.); *allophanate*, $C_{15}H_{20}N_2O_4$, m. 214°. Although condensation of MeCH.$CHCH_2Br$ with I yields both coumaran and chroman derivs. condensation with CH_2:$CHCH_2Br$ gives only the coumaran compd. whereas $Me_2C.CHCH_2Br$ (VI) produces only the chroman compd. and consequently the form of the deriv. depends on the mode of substitution of the 3rd C atom of the unsatd. halogen compd. VI was prepd. by the action of 50 g. PBr_3 in 50 cc. petr. ether at −5° for 1 hr. on 15 g. of $Me_2C(OH)$-CH:CH_2 in 100 cc. of petr. ether at −15° in the presence of CO_2. Overnight the temp. rose to 10–15°. After stirring for 1 hr. at room temp., the reaction mixt. was poured over ice and extd. with ether, yielding 40% (9 g.) of VI. A mixt. of 4.5 g. VI, 5 g. I and 3.0 g. $ZnCl_2$ was heated for 3 hrs. in a N atm. until evolution of HBr ceased. H_2O was added and the mixt. was extd. with benzene. Crystn. of the crude product from petr. ether and from alc. gave 1.3 g. of colorless crystals of *2,2,5,7,8-pentamethyl-6-hydroxychroman*, $C_{14}H_{20}O_2$, m. 95°. Absorption spectra measurements of the allophanates of II (log ε 2.760, max. 286.0 mμ; log ε 1.805, min. 251.5 mμ), III (log ε 2.980, max. 288.5 mμ; log ε 2.040, min. 253.5 mμ) and 2,4,6,7-tetramethyl-5-hydroxycoumaran (log ε 3.010, max. 287.5 mμ; log ε 2.070, min. 253.5 mμ), show that the coumaran allophanates exhibit a somewhat higher extinction coeff. than the allophanate of the isomeric chroman compd. Cryoscopic mol.-wt. detns. in benzene of the red oxidation compd. (VII) obtained by continued boiling of II, or its quinoid oxidation product, with excess of $AgNO_3$ in MeOH (*C. A.* **33**, 6310[1]) establish the simple formula $C_{13}H_{14}O_3$ (detns. in camphor corresponded to a bimol. product). The red quinones obtained by $AgNO_3$ oxidation of tocopherols are chromanquinones and VII is designated as 2,6,7-trimethylchroman-5,8-quinone. C. R. Addinall

Steric relations of α-tocopherol and further investigation of lower homologs of α-tocopherol. P. Karrer, H. Koenig, B. H. Ringier and H. Salomon. *Helv. Chim. Acta* **22**, 1139–45(1939); cf. *C. A.* **32**, 7035[9], 7036[8].—α-Tocopherol (I) contains 3 asym. C atoms in positions 2 in the chroman ring and 4′, 8′ in the side chain. Phytol (II) from chlorophyll shows no optical activity and may be a racemate, a mixt. of 2 racemates or a single latent optically active form. A small prepn. of *dl*-α-tocopherol allophanate from

synthetic II m. 3–4° lower than a similar prepn. from natural II. Prepns. of racemic I on a larger scale have shown that the 3,5-dinitrobenzoate, m. 66–7°, allophanate, m. 174–5°, and *p*-nitrophenylurethan, m. 130–1°, are independent of the source of II and that racemic I from natural II is a racemic compd. or a mixt. of racemates in regard to the asym. centers at positions 4′ and 8′. Since 8 isomeric active components are present in racemic I the previous isolation of the bromocamphorsulfonate and comparison with the corresponding salt of natural I has been repeated. Repeated fractional crystn. from alc. gave a difficultly sol. compd., m. 73°, $[\alpha]_D$ 39.6 ± 3° (bromocamphorsulfonate from natural I, $[\alpha]_D$ 39.9 ± 3°), and a more readily sol. compd. (III), m. 52° (bromocamphorsulfonate from natural I, m. 52°). III is probably a difficultly separably mixt. of several diastereomers. Synthetic I has the same physiol. activity as natural I and shows 100% activity in doses of 2–3 mg. The 3 isomeric racemic di-Me tocols (5, 8 (IV); 7,8 (V); 5,7) and *dl*-5,7-dimethyl-8-ethyltocol also show 100% activity in rats in doses of 6, 10, 10 and 10 mg., resp. I is the most effective and its activity is reduced by elimination of a Me group or conversion to an Et group. The dimethyltocols are readily prepd. in good yields by direct condensation of II with the requisite dimethylhydroquinone. A mixt. of 5 g. 2,5-dimethylhydroquinone, 11 g. II and 50 cc. anhyd. HCO_2H was refluxed in a N atm. for 5 hrs. with good mixing by the current of N. The cooled reaction product was poured into H_2O and the oily layer was extd. with ether. The washed and dried ext. was evapd. to dryness *in vacuo* and the 11 g. of brownish oil was boiled with 1.5 g. Na in 40 cc. MeOH in a N atm. for 1 hr. After diln. with 4 vols. of H_2O the product was extd. with ether, yielding 10 g. of oil which was taken up in petr. ether, adsorbed on an Al_2O_3 column and developed with 800 cc. petr. ether. Elution of the 2 central zones and treatment of the oils in benzene with HCNO gave IV *allophanate*, m. 151° (4.76 g. from 5 g. quinone and 10 g. II); *p-nitrophenylurethan*, m. 112°. Similarly 2 g. of 2,3-dimethylhydroquinone and 4 g. II yielded 0.5 g. of V *allophanate*, m. 146° (crystd. from alc. and acetone).

C. R. Addinall

New derivatives of 2-aminomethyltetrahydroquinoline and [1-aminomethyl]tetrahydroisoquinoline. Alois Gassmann and H. Rupe. *Helv. Chim. Acta* **22**, 1241–62 (1939); cf. *C. A.* **33**, 6317⁶. To a mixt. of 225 g. KCN in 1.5 l. H_2O and 150 g. 6-methoxyquinoline cooled to 5° was added gradually with vigorous stirring 337 g. BzCl and after 1 hr. the supernatant liquid was carefully poured off, washed 2 times with dil. HCl and H_2O and crystd. from alc., giving 243 g. (89% of theory) *1-benzoyl-2-cyano-6-methoxy-1,2-dihydroquinoline* (I), prismatic needles, m. 127°, from benzene (*amide oxime*, m. 148–9° (decompn.)), and, as a by-product from the mother liquor, *2-cyano-6-methoxyquinoline* (?) (II), m. 176–7°. Treating 5 g. II with a mixt. of 60 cc. pure HCl and 100 cc. ether with boiling gave the corresponding *acid amide*, whose *HCl salt* m. 237–8° after softening at 225°, while treatment with 30 cc. concd. HCl under reflux gave after a few hrs. the corresponding *acid*, m. 235–6° after softening at 233–4°; the position of the 2(?)-substituent in II and its derived products was not established with certainty. Reduction of 150 g. I in 400 cc. AcOEt with 100 g. freshly reduced Ni catalyst at 120 atm. and about 90° gave 110 g. *benzoyl-6-methoxytetrahydroquinoline-2-methylamine* (III), m. 131–2°. Treating 5 g. II in 15 cc. AcOH with 2 cc. concd. HCl and, with good cooling, 1.2 g. $NaNO_2$ in water gave *1-nitroso-2-benzoylaminomethyl-6-methoxytetrahydroquinoline*, yellow, m. 130–9°, from alc. Heating 100 g. III in 250 cc. concd. HCl for 15 hrs. gave BzOH and, upon treating with alkali and extn. with ether, 45 g. (70% of theory) *2-aminomethyl-6-methoxytetrahydroquinoline* (IV), b_{12} 196–7°; *di-HCl salt*, m. 224–5°; *tartrate*, m. 195° (decompn.); *perchlorate*, m. 278°. Warming 20 g. IV with 16 g. piperonal on a water bath gave a clear soln. which became turbid from the H_2O liberated and, after 12 hrs., formed a bright yellow, resinous mass which would not crystallize, but was dissolved in 350 cc. MeOH and shaken with H, using 25 g. freshly reduced Ni catalyst at 100 atm. initial pressure and 65°, giving, after purification through the HCl salt, *2-(3,4-methylenedioxybenzylaminomethyl)-6-methoxytetrahydroquinoline*, m. 53–4°, from ligroin; *mono-HCl salt*, m. 212–13°; *di-HCl salt*, m. 179–80° after softening at 171°; the base forms a difficultly sol. *sulfate*, *nitrate*, *HCl salt*, *phosphate*, *oxalate*, *perchlorate*, and *picrate*. Condensing 25 g. IV with 22 g. veratraldehyde for 15 hrs. on a water bath gave the corresponding Schiff base as a thick, resinous, faintly yellow oil which was hydrogenated at 100 atm. initial pressure at 70° to *2-(3,4-dimethoxybenzylaminomethyl)-6-methoxytetrahydroquinoline*, purified through its *HCl salt*, m. 182–3° after softening at 179°; the corresponding *sulfate*, *nitrate*, *HCl salt*, *phosphate*, *formate*, *oxalate*, *perchlorate*, and *picrate* are difficultly sol. while the *acetate*, *citrate*, and *tartrate* are readily sol. Condensing 35 g. of *1-aminomethyltetrahydroisoquinoline* (V) (cf. R. and Frey, *C. A.* **33**, 6317⁶) gave the corresponding Schiff base as a brown, resinous, thick oil, which was dissolved in 300 cc. MeOH and reduced with 30 g. Ni catalyst at 90 atm., giving, after purification through the HCl salt, *1-(3,4-methylenedioxybenzylaminomethyl)tetrahydroisoquinoline* as a bright yellow oil; *di-HCl salt*, m. 248–9° (decompn.); the corresponding HCl salt, *sulfate*, *nitrate*, *HBr salt*, *picrate*, *perchlorate*, *oxalate*, and *phosphate* are difficultly sol., while the *formate*, *acetate*, *tartrate*, and *citrate* are readily sol. Condensing 40 g. of V with 40 g. veratraldehyde on the water bath for 12 hrs., followed by catalytic hydrogenation of the resulting thick, oily Schiff base in 300 cc. MeOH with 35 g. Ni catalyst at 65° and 105 atm. gave, after purification through the oxalate, *1-(3,4-dimethoxybenzylaminomethyl)tetrahydroisoquinoline; oxalate*, m. 197° (decompn.); *HCl salt*, m. 221°. Reduction of 20 g. 1-nitroso-2-benzoylaminomethyltetrahydroquinoline (cf. R., Paltzer and Engel, *C. A.* **31**, 3923²) in 200 cc. alc. and 80 cc. 50% AcOH with 16 g. Zn dust gave 37 g. of the *Zn acetate double salt*, m. 245°, of *1-amino-2-benzoylaminomethyltetrahydroquinoline* (VI), m. 156°, purified by dissolving in dil. HCl and then treating with NaOH. VI possesses properties characteristic of a hydrazine and from it the following were prepd.: *benzal deriv.*, m. 158–9°, which upon warming with dil. HCl cleaves into its components; *piperonal deriv.*, sintering at 182°, m. 184–5°; *acetophenone condensation product*, m. 161–2°. The previously described sapon. of the hydrogenated "Reissert" compd., 2-benzoylaminomethyltetrahydroquinoline (*Ber.* **38**, 1610(1905)), to 2-aminomethyltetrahydroquinoline (VII) was improved, with a yield of 93–95%, by refluxing 100 g. of the hydrogenated product with 250 cc. concd. HCl for 16–18 hrs. VII (15 g.) in 100 cc. abs. alc., to which was added 7.5 g. anhyd. pyridine, with 13 g. nicotinyl chloride in 50 cc. abs. ether gave 16.5 g. of *1-nicotinyl-2-(nicotinylaminomethyl)tetrahydroquinoline*, m. 175–6°. VII (16 g.) in 50 cc. abs. benzene with 19 g. veratroyl chloride in 150 cc. abs. benzene gave 21 g. of *1-veratroyl-2-veratroylaminomethyltetrahydroquinoline*, m. 168°, crystd. from benzene and then from alc. Condensing 40 g. VII with 40 g. veratraldehyde by warming on a water bath gave an oily product which formed a difficultly sol. *picrate* and, upon dissolving in 300 cc. MeOH and reducing with 30 g. Ni catalyst at 90 atm., gave 61 g. (77.5% of theory) of *2-(3,4-dimethoxybenzylaminomethyl)tetrahydroquinoline*, m. 75°; the latter forms Au salts, gives a difficultly sol. $ZnCl_2$ *compd.* and salts such as the *HCl salt*, m. 191–2°, *HBr salt*, *nitrate*, *sulfate*, m. 161.5°, and *thiocyanate* and an easily sol. *acetate* which readily undergoes hydrolysis. Condensing 20 g. VII with 19 g. piperonal gave a thick, resinous oil, which formed a yellow *picrate* and a *perchlorate*; reduction of the crude condensation product with 20 g. catalyst at 80 atm. and 65° gave as an oil *2-(3,4-methylenedioxybenzylaminomethyl)tetrahydroquinoline; HCl salt*, m. 213–14°; *sulfate*, m. 177–8°; *phosphate*, m. 204–5°. Treating 24.5 g. of 1-methyl-2-aminomethyltetrahydroquinoline (VIII) (cf. R., Paltzer and Engel, *C. A.* **31**, 3923²) and 11.2 g. dry pyridine in 100 cc. abs. ether with 20 g. nicotinyl chloride in abs. ether gave 33.5 g. (85% of theory) of *1-methyl-2-(nicotinylaminomethyl)tetrahydroquinoline* (IX), yellow-green, m. 159–160°, most of whose salts are readily sol. in H_2O and form indigo- or cornflower-

blue solns. upon standing. IX forms both the theoretically possible *HCl salts*, a white *di-HCl salt*, sintering at 223° and a yellow *mono-HCl salt*, m. 223°, both of which can be interconverted, depending upon manner of prepn. (transformation equations are given). VIII (26.2 g.) in 11.7 g. dry pyridine and 100 cc. abs. benzene with 25 g. veratroyl chloride in 150 cc. abs. benzene gave 38.5 g. (83% of theory) of *1-methyl-2-veratroylaminomethyltetrahydroquinoline*, m. 161–2°, from alc.; *HCl salt*, m. 179–80°, tends to hydrolyze to the free base in H_2O and turns deep red upon standing, again reverting to the free base. Condensing 35 g. VIII with 35 g. piperonal followed by catalytic reduction in 300 cc. MeOH with 35 g. freshly reduced catalyst at 90 atm. and 65° gave *1-methyl-2-(3,4-methylenedioxybenzylaminomethyl)tetrahydroquinoline*, as a thick, yellow oil, whose salts, such as the *HCl salt*, m. 207–8°, *HBr salt* and *phosphate* are difficultly sol. Condensing 15 g. of VIII with 15 g. veratraldehyde followed by catalytic reduction in 250 cc. MeOH with 20 g. Ni at 85 atm. and 70° gave *1-methyl-2-(3,4-dimethoxybenzylaminomethyl)tetrahydroquinoline*, as a thick, yellow oil, whose *sulfate*, *HBr salt*, *phosphate* and org. acid salts are extremely difficultly sol.; *perchlorate*, m. 193° (decompn.).

John F. Lontz

2-Aminomethyltetrahydroquinoline and its derivatives. Helmut v. Bidder and H. Rupe. *Helv. Chim. Acta* 22, 1268–78(1939); cf. *C. A.* 33, 6317[6] and preceding abstr.— The following derivs. of *2-aminomethyltetrahydroquinoline* (I) were prepd. by hydrogenating the "Reissert" compd., 1-benzoyl-2-cyano-1,2-dihydroquinoline, and then sapong.; *mono-HCl salt*, m. 257°; *di-HCl salt*, m. 265° (decompn.); *mono-HBr salt*, m. 235–6° (decompn.); *Ac deriv.* using Ac_2O, $C_{14}H_{18}N_2O_2.2H_2O$, m. 48.5–49.5°; *benzal deriv.* m. 75–6°; *monoformate*, m. 117.5–18.5°; *monoformyl deriv.*, b_{10} 178–80°, m. above 20° but below 40° (*perchlorate*); *glycine Et ester deriv.*, $C_6H_4.CH_2.CH_2.CHR.NR'$ (II) (R=$CH_2NHCH_2CO_2Et$; R'=H) obtained by treating 20 g. of the base in 100 cc. benzene dropwise with 6.9 g. $ClCH_2CO_2Et$, could not be purified by distn. but forms a well-characterized *neutral oxalate*, m. 169–70° (decompn.); *urethan deriv.*, obtained by adding 6.72 g. $ClCO_2Et$ in 20 cc. $CHCl_3$ to 20 g. of base in 80 cc. $CHCl_3$ with good cooling (ice-HCl), giving 10.2 g. (70%) of the *II Cl salt* (m. 135.5°) from which is obtained the free ester as a colorless oil, b_{10} 120–5° (*perchlorate*, m. 124°); *imidazolone*, obtained by refluxing for 2 hrs. 20 g. of base in 60 cc. benzene with 6.72 g. $ClCO_2Et$ in 7.35 g. yield as a oil, b_{10} 245–7°, which solidifies and m. 197°, or more conveniently by introducing $COCl_2$ into an ether soln. of the base in the cold. Treating 50 g. of I with 30 g. ethylene oxide in a sealed tube in a boiling water bath gave 35 g. yield (crude) of *2-[bis(β-hydroxyethyl)amino]methyltetrahydroquinoline* (III), m. 92–3°, whose structure is not quite certain since smaller amts. of the corresponding *monohydroxyethyl deriv.*, m. 105.5–6.5°, sepd. by fractional distn., was always obtained as a by-product. III forms a *mono-Bz deriv.*, m. 115–6°, using BzCl in presence of K_2CO_3, and a *tri-Bz deriv.*, m. 95–6°, using BzCl in presence of C_5H_5N; the latter forms a *primary diorthophosphate*, m. 151 5° (decompn.), and a *mono-HCl salt*, m. 100.5–103.5° (decompn.). Treating 30 g. of the hydrogenated "Reissert" compd. with 20 g. ethylene oxide in a sealed tube in a shaking Carius oven for 24 hrs. at 110–120° gave 30 g. of *1-(2-hydroxyethyl)-2-benzoylaminomethyltetrahydroquinoline* (IV), m. 113–14.5°; use of solvents in this synthesis gave very small yields. Treating 20 g. of the *N*-methylamino compd. (*primary dicarbonate*, m. 123–5°) of I (cf. *C. A.* 31, 3923[3]) with 10 g. ethylene oxide for 2 hrs. at 110–20° gave (after the 2nd distn.) *1-methyl-2-bis(2-hydroxyethyl)aminomethyltetrahydroquinoline*, $b_{0.005}$ 177–9°, which failed to crystallize but showed definite basic properties; heating the base with epichlorohydrin at 100° gave the HCl salt of the original base and a thick yellow oil which forms a non-crystallizable HCl salt and a Bz or Ac deriv., but a more useful product could be obtained by applying the reaction to the Bz deriv. of the base. Thus treating 50 g. of the hydrogenated "Reissert" compd. with 140 g. epichlorohydrin in a sealed tube for 14 hrs. in a H_2O bath gave *2-benzoylaminomethyltetrahydroquinolyl-1-propylene oxide [2-(benzoylaminomethyl)-1-(2,3-epoxypropyl)tetrahydroquinoline]*, m. 118–19°; with $ClCH_2COMe$ and $PhCOCH_2Br$, in ether the corresponding salts of the base were formed but upon removal of the ether a violent reaction occurred with the formation of a dark brown resin; in the latter case, by using toluene and C_5H_5N, the compd. II (R=CH_2NHBz, R'=CH_2Bz), m. 163°, was obtained. Refluxing 1 mol. I with α-propyl-α-methylethylene oxide (cf. Fourneau and Samdahl, *C. A.* 25, 517) for 4 hrs. at 120–130° and treating the reaction product with dil. HCl gave the *mono-HCl salt*, m. 171–3° (decompn.), of the compd. II (R=CH_2NHCH_2CMePr-OH, R'=H); the free base is a thick yellow oil.

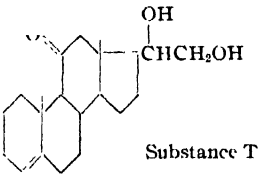
John F. Lontz

Cardiac glucosides. XV. Periplocin, the true cardiac glucoside of Periploca graeca. Arthur Stoll and Jany Renz. *Helv. Chim. Acta* 22, 1193–1208(1939); cf. *C. A.* 32, 2947[8].— With the exception of ouabain the genuine cardiac glucosides consist of a combination of aglucon, desoxy sugar and glucose. The specific enzyme of the drug cleaves only the linkage between the sugars whereas the aglucon-desoxy sugar linkage is broken only by acid hydrolysis. The investigations of Jacobs, Elderfield, *et al.*, (*C. A.* 25, 4888, 5172, 5173) have shown that the aglucon of *Periploca graeca*, periplogenin (I), is a desoxostrophanthidin or hydroxydigitoxigenin and that the sugar residues are attached through the HO group at position 3. Wood and bark collected in Smyrna by Renz were worked up within 4 weeks of collection. Dried and finely ground stalks and bark (1 kg.) were thrice extd. for 10 hrs. with 10 l. alc. to avoid enzymic cleavage since strophanthobiase is known to be inactive in aq. alc. The green ext. was concd. *in vacuo* at low temp. and the resinous residue was worked up with ether. The greenish powder (50 g.) was taken up in 92% alc., treated with $Pb(OH)_2$, freed from Pb with H_2S, evapd. to 1 l. *in vacuo* and extd. with $CHCl_3$. Evapn. *in vacuo* yielded 20–25 g. of residue which was thrice extd. with a mixt. of 400 cc. H_2O, 400 cc. $CHCl_3$ and 200 cc. alc. The 5 g. residue from the combined $CHCl_3$ layers contained practically the entire crude glucoside. Acetylation for 12 hrs. with Ac_2O in pyridine gave 7.3 g. of crude acetylated product, recrystd. from alc., yielding 1.8 g. of hexagonal flat prisms of *tetraacetylperiplocin* (II), $C_{44}H_{64}O_{17}$, m. 195°, $[\alpha]_D^{19}$ 20.0° (*c* 0.4508 in abs. alc.), hydrolyzed by standing for 2 days with H_2SO_4 at room temp. (after neutralization with NaOH and isomerization) to the known isoperiplogenin, m. 248°. II (0.476 g.) in 20 cc. abs. MeOH was treated with 0.80 cc. $(MeO)_2Ba$ (equiv. to 2.14 cc. 0.1 *N* H_2SO_4) for 13 hrs. at 0°. The Ba was pptd. with an equiv. amt. of 0.1 *N* H_2SO_4 and the soln. was evapd. to dryness *in vacuo*. The residue (0.380 g.) was taken up in alc., dild. with H_2O, and freed from alc. The filtered aq. soln. gave hydrated crystals which were recrystd. from acetone to yield thin leaflets of *periplocin* (III), $C_{36}H_{56}O_{13}$, m. 224° (decompn.; in bath preheated to 200°), $[\alpha]_D^{19}$ 22.9 (*c* 0.6988 in MeOH), giving a Liebermann reaction changing from red to green but no characteristic Keller-Kiliani reaction. This careful alk. sapon. gave the original glucoside in the intact form without splitting the alkali-sensitive lactone ring since sapon. in aq. media needed 5 equivs. of alkali in place of the 4 equivs. calcd. in the above cleavage. Acid hydrolysis of III gave the aglucon, I, and a new disaccharide, *periplobiose* (IV), similar to, but not identical with, strophanthobiose (V), m. 208°, $[\alpha]_D^{19}$ 31°. III (0.3665 g.) in 10 cc. abs. alc. was treated with 10 cc. of 0.1 *N* H_2SO_4 for 12 hrs. at 25° and for 2 hrs. at 40–50°. After diln. with H_2O, the aglucon was thoroughly shaken out with $CHCl_3$ and the ext. was evapd. to dryness *in vacuo*, yielding 54.1% (calcd. 56%) of I, m. 232°, $[\alpha]_D^{19}$ 29.8°, after recrystn. from dil. MeOH. The aq. layer was neutralized with $BaCO_3$, filtered and evapd. to dryness *in vacuo*. The colorless residue was taken up in MeOH, filtered and evapd., yielding 44.2% (calcd. 46.55%) of IV, $C_{12}H_{24}O_8$, m. 160–70°, $[\alpha]_D^{19}$ 30.8° 32.0°, reducing Fehling soln. and giving an orange-brown

boundary zone in the Keller-Kiliani reaction (free cymarose gives a cornflower-blue AcOH layer). Like strophanthobiose, **IV** is difficultly saponifiable with acids. Enzymic hydrolysis of **III** with strophanthobiase (*C. A.* **20**, 3013) splits out glucose and the resulting periplocymarin (**VI**) was sol. in $CHCl_3$. Extn. of the cleavage products from 300 mg. **III** with $CHCl_3$ yielded 210 mg. **VI** (90.5%). Recrystn. from dil. MeOH gave prisms of **VI**, $C_{30}H_{46}O_8$, m. 143–5°, $[\alpha]_D^{20}$ 27.6° (*c* 0.1628 in MeOH), identical with the prepn. described by Jacobs (*C. A.* **23**, 151). The glucose component was identified by the characteristic phenylglucosazone, m. 207°. Acetylation of **IV** and **V** gave cubic crystals of *pentaacetylperiplobiose*, $C_{23}H_{34}O_{14}$, m. 184°, $[\alpha]_D^{20}$ 13.2°; 13.3°. Since in both **IV** and **V** the sugar linkage (cymarose-glucose) is β-glucosidic in nature the difference between the 2 disaccharides may reside in a position isomerism of the forms 1(β)-glucosido-4-cymarose and 1(β)-glucosido-5-cymarose. Tables are given to compare the data of Lehmann (*Arch. Pharm.* **235**, 157(1897)) on **III** and **I** with those obtained in more recent investigations, and to compare the cardiac glucosides and derivs. from *S. kombe* and *P. graeca*. The av. lethal dose in frog units per mg. for **III** is 200–300. The corresponding value for digitoxin is about 400. C. R. Addinall

Syntheses in the steroid series. Elisabeth Dane. *Angew. Chem.* **52**, 655–9(1939).—A comprehensive summary with many formulas and 35 references. Karl Kammermeyer

Bile acids of turtle bile: trihydroxysterocholanic lactone. Chai Heung Kim. *J. Biochem.* (Japan) **30**, 247–9 (1939).—A tri-HO lactone, m. p. 208°, was isolated from turtle (*Emys orbicularis*) bile. It was identified by its formyl ester and by its tetraketone acid deriv. S. M.



α- and β-3-Keto-7-hydroxycholanic acid. Sigeki Miyazi and Hideo Isaka. *J. Biochem.* (Japan) **30**, 297–302 (1939).—By partial hydrolysis of diformylchenodesoxycholic and diformylursodesoxycholic acid 2 different products were obtained, α- and β-3-hydroxy-7-formylcholanic acid, from which α- and β-3-keto-7-hydroxycholanic acids were obtained by successive oxidation and hydrolysis. Crystd. from AcOEt the α-form m. 96°, and crystd. from dil. alc. the β-form m. 117°. S. Morgulis

Tetrahydroxycholane, trihydroxycholene, and trihydroxybisnorsterocholanic acid from the bile of Rana catesbina Shaw. Yukiti Kurauti and Taro Kazuno. *Z. physiol. Chem.* **262**, 53–60(1939).—The ether ext. of bile from *R. catesbina* contained *trihydroxybisnorsterocholanic acid*, m. 172°, which gives a Liebermann reaction but no Hammersten reaction and is satd. Oxidation with CrO_3 in HOAc gives *triketobisnorsterocholanic acid*, $C_{26}H_{38}O_5$, m. 230–1°. The residual bile was freed of mucin with alc. and then NaCl added. A substance was salted out which on purification is shown to be the *Na salt* of a *tetrahydroxycholanesulfuric acid*, $C_{24}H_{41}O_4NaSO_3(H_2O)$, $[\alpha]_D^{18}$ 8.7°. It is stable to active H, $KMnO_4$ and Br. Hydrolysis with 15% KOH gave a *trihydroxycholene* (**I**), $C_{24}H_{40}O_3$, m. 177°, $[\alpha]_D^{18}$ 34.4°. This takes up 1 mol. of H to form *trihydroxycholane* (**II**), $C_{24}H_{42}O_3(H_2O)$, m. 185–6°, $[\alpha]_D^{18}$ 31.5°. **I** forms a *diacetate*, m. 180°, and a noncryst. triacetate. Oxidation of **I** gave a *triketocholene*, m. 240–2°, yielding a *trioxime*, m. 247°. The compd. gives a neg. Jaffé reaction, indicating that no keto group is at C_3. **II** gave a *triketocholane*, m. 245° and giving no Jaffé reaction. **I** gives an oil on Clemmensen reduction and on bromination gives a *di-Br compd.*, m. 180°. Milton Levy

Constituents of the adrenal cortex and related compounds. XXVIII. Allopregnane-3,21-diol-20-one diacetate and allopregnan-21-ol-3,20-dione acetate. T. Reichstein and J. v. Euw. *Helv. Chim. Acta* **22**, 1209–12 (1939).—The compds. *allopregnane-3,21-diol-20-one diacetate* (**I**) and *allopregnan-21-ol-3,20-dione acetate* (**II**), required for purposes of comparison, were prepd. from 3(β)-acetoxyetioallocholanic acid (**III**) by a method analogous to that used in the prepn. of desoxycorticosterone (*C. A.* **32**, 581[3]). A mixt. of 4.5 g. **III**, m. 247° (all m. ps. cor.) and 23 cc. of purest $SOCl_2$ was kept at 5° for 16 hrs., evapd. to dryness *in vacuo*, taken up in 50 cc. abs. Et_2O and added to ethereal CH_2N_2 (from 15 g. $H_2NCONHCH_2NO$) at −10°. After 3 hrs. at 0° and 16 hrs. at room temp. the reaction mixt. was concd. and, after filtration, taken down to dryness *in vacuo*. Crystn. of the residue (5.5 g.) from an ether-pentane mixt. gave *21-diazoallopregnan-3-ol-20-one acetate* (**IV**), m. 134.0–4.5° (decompn.), converted by boiling with AcOH to **I**. Sapon. of 5.5 g. **IV** by treatment with 4 g. KOH in 5 cc. H_2O and 250 cc. MeOH at room temp. for 4 hrs., diln. with 300 cc. H_2O, evapn. of the MeOH and extn. with Et_2O yielded 4.2 g. of crude *21-diazoallopregnan-3-ol-20-one*, m. 170–2° (decompn.), converted by warming with 40 cc. AcOH at 95–100° for 30 min. until evolution of N ceased. Recrystn. of the product from acetone-pentane and from MeOH produced 2.65 g. of colorless needles of *21-acetoxyallopregnan-3-ol-20-one* (**V**), $C_{23}H_{36}O_4$, m. 202–4°, acetylated by treating with Ac_2O in pyridine at room temp. for 24 hrs. to **I**, $C_{25}H_{38}O_5$, m. 151.0–2.5°. Oxidation of 200 mg. **V** with 150 mg. CrO_3 in 10 cc. of pure AcOH for 4 hrs. at room temp. and crystn. of the crude product from MeOH yielded fine needles of **II**, $C_{23}H_{34}O_4$, m. 197–9° (mixed m. p. with **V**, 180–96°). **I**, **II** and **V** reduce alk. Ag diammine strongly at room temp.

XXIX. Action of lead tetraacetate on allopregnanolone acetate, pregnanolone acetate and progesterone. T. Reichstein and C. Montigel. *Ibid.* 1212–21.—According to Dimroth and Schweizer (*C. A.* **17**, 3319) by heating with $Pb(OAc)_4$ in AcOH, 1 or 2 AcO groups can be introduced into a ketone in the neighborhood of the CO group. The introduction of AcO groups by this method into the $CHCOMe$ side chain of pregnane derivs. has been investigated. A mixt. of 0.5 g. of allopregnanolone acetate and 1.1 g. of pure $Pb(OAc)_4$ in 15 cc. anhyd. AcOH contg. 0.25 cc. Ac_2O was warmed at 68–70° for 24 hrs. The reaction product was evapd. *in vacuo*, suspended in H_2O and extd. with Et_2O. The washed and dried ext. was evapd. and taken up in benzene. The benzene soln. was dild. with an equal vol. of pentane and filtered through a 15-g. column of Al_2O_3. The column was washed with 900 cc. of benzene-pentane (1 1) and eluted with 250 cc. of benzene-ether (1 1). The residue from the benzene-pentane was recrystd. from ether-pentane and yielded 307 mg. of allopregnane-3,21-diol-20-one diacetate (**I**), m. 152.0–3.5°. The residue from the benzene-ether eluate was crystd. from ether-pentane and from ether, giving 11 mg. of colorless needles of slightly impure *allopregnane-3,17,21-triol-20-one triacetate* (**II**), $C_{27}H_{40}O_7$, m. 190–2°, reducing alk. Ag diammine in 1 min. Partial sapon. of 14 mg. **II** in 4 cc. of warm MeOH by treatment with 14 mg. $KHCO_3$ in 0.4 cc. H_2O for 44 hrs. gave 12 mg. of product sapond. in the 21-position (*C. A.* **33**, 1337[8]). Oxidation of this product in 1.7 cc. MeOH with 20 mg. HIO_4 in 1 cc. H_2O and 1 cc. MeOH in the presence of 0.15 cc. 2 *N* H_2SO_4 at room temp. for 16 hrs., extn. with Na_2CO_3, acidification and extn. with Et_2O gave 8.5 mg. of crude cryst. acid, m. 230–62°, which was sapond. by refluxing for 2 hrs. with 10 mg. KOH in 1.5 cc. MeOH. Acidification and extn. with Et_2O yielded 4 mg. of 3(β),17(β)-dihydroxyetioallocholanic acid, m. 272–4° (Me ester, m. 238–42°), identical with the product obtained by degradation of substance P from the adrenal cortex (*C. A.* **33**, 1338[8]). Accordingly **II** is the triacetate of substance P. **I** is not converted into **II** by heating with $Pb(OAc)_4$ in AcOH. It appears that the main reaction is an acetylation in position 21 and that the secondary reaction is an acetylation in position 17 followed by a further acetylation in position 21. Similarly 0.6 g. of pregnenolone acetate was converted by $Pb(OAc)_4$ in AcOH to give 132 mg. of hexagonal leaflets of 5-pregnene-3,21-diol-3-one diacetate, $C_{25}H_{36}O_5$, m. 164° (*C. A.* **32**, 581[4]), corresponding to the product obtained by this method by Ehrhart and coworkers (*C. A.* **33**, 6327[7]), and 12 mg. of colorless needles of the probable *pregnenetriolone triacetate*, $C_{27}H_{38}O_7$, m. 182–5°, reducing alk. Ag diammine strongly. The conversion of progesterone in good yields into desoxycorticosterone acetate (**III**) by heating with $Pb(OAc)_4$ in AcOH, distn. of the crude product in high vacuum and recrystn. is claimed in the I. G. patent, Brit. 502,474 (*C. A.* **33**, 7316[8]), and is also described by Ehrhart, *et al.* Careful repetition of example 3 of the patent cited, followed by laborious chromato-

graphic analysis, gave 3% of **III**, m. 158–60°. The method proposed by the patent is considered by R. and M. to be unpractical and the communication of Ehrhart is supposedly based on error. **XXX. Substance T.** T. Reichstein and J. v. Euw. *Ibid.* 1222–7.—The benzene residues from fraction C.17.A.2 (*C. A.* **32**, 7051[8]) of the amorphous mother concentrates from adrenal cortical exts. consist of a light-brown glassy mass (**I**). Sapon. of 1.6 g. **I** in 130 cc. MeOH by standing with 1.6 g. $KHCO_3$ in 30 cc. H_2O at room temp. for 44 hrs., evapn. of the MeOH and extn. with benzene gave 1.54 g. of amorphous material (**II**). Acetylation of **II** in 8 cc. of dry pyridine with 5 cc. Ac_2O for 44 hrs. at room temp. and extn. with Et_2O gave 1.8 g. of acetylated product which was chromatographically sepd. into the acetates of substance N, dehydrocorticosterone, corticosterone, substances S, Fa and M, and 38 mg. of pure *substance T diacetate* (**III**), $C_{25}H_{34}O_6$, m. 212–3°, and 25 mg. of less pure **III**. Similarly 2.04 g. of the benzene-sol. portion of fraction C.17.A.3 (*C. A.* **32**, 577[8]) gave 20 mg. **III**. **III** does not reduce alk. Ag diammine at room temp. and has therefore no ketol grouping in the side chain. It shows a strong band in the ultraviolet absorption spectrum with a max. at 240 mμ, characteristic of an α,β-unsatd. ketone. **III** (20 mg.) in 2 cc. MeOH was refluxed for 1 hr. with 9 mg. K_2CO_3 in 0.1 cc. H_2O and the crude free *substance T* (**IV**) was oxidized with CrO_3 in AcOH to 3,11-diketoetio-4-cholenic acid, m. 265–75° (Me ester, m. 178–80°), identical with Kendall's acid 1 (*C. A.* **31**, 8537[8]), also obtained by oxidation of corticosterone and dehydrocorticosterone with CrO_3. Since **III** is not oxidized by CrO_3 it cannot have a HO group in the 11-position. Accordingly, **IV** has the assigned formula and is a further isomer of corticosterone that can scarcely be expected to have biol. activity.

C. R. Addinall

Steroids and sex hormones. LV. Preparation of 3-hydroxy-5,7-pregnadiene-21-carboxylic acid and its reduction products. Pl. A. Plattner and W. Schreck. *Helv. Chim. Acta* **22**, 1178–84(1939); cf. *C. A.* **33**, 6869[8]. In the course of investigations on the building up of the side chain of 17-keto steroids by the Reformatzky reaction, *3-hydroxy-5,17-pregnadiene-21-carboxylic acid* (**I**) and its derivs. were prepd. and also 3,17-dihydroxy-5-androstene-17-acetic acid (**II**) and its derivs., recently studied by Reichstein, *et al* (*C. A.* **33**, 6330[2]). **II** gave the *Me ester*, $C_{22}H_{34}O_4$, m. 159°, $[\alpha]_D$ −89 ± 2° (*c* 0.994 in $CHCl_3$); *3-acetyl Me ester*, $C_{24}H_{36}O_5$, m. 117°, $[\alpha]_D$ −68 ± 2° (*c* 0.995 in $CHCl_3$); *3,17-diacetyl Me ester*, $C_{26}H_{38}O_6$, m. 113° and 121° (2 crystal forms), $[\alpha]_D$ −70 ± 2° (*c* 0.968 in $CHCl_3$), converted by distn. at 15 mm. over a free flame and recrystn. from MeOH to *Me 3-acetoxy-5,17-pregnadiene-21-carboxylate* (**III**), $C_{24}H_{34}O_4$, m. 159°, $[\alpha]_D$ −69 ± 2° (*c* 1.01 in $CHCl_3$), also prepd. by direct methylation and acetylation of **II** and distn. at 11 mm. The absorption spectrum, showing an extinction max. at 230 mμ, indicated that the cleavage of AcOH had taken place at position 17 with formation of a double linkage conjugated with the CO_2Me group. Total sapon. of 650 mg. **III** by refluxing for 1 hr. with 50 cc. of 5% KOH in MeOH and acidification gave 530 mg. of crude **I**, $C_{21}H_{30}O_3$, m. 249–50°, $[\alpha]_D$ −82 ± 1° (*c* 0.998 in dioxane), after sublimation in high vacuum; *Me ester* (**IV**), m. 188–9°, $[\alpha]_D$ −73 ± 1° (*c* 0.994 in dioxane), showing an absorption curve similar to that of **III**. Thus in the sapon. no shift of the conjugated double bond took place. A mixt. of 320 mg. **IV** in 8 cc. acetone and 0.8 g. $(tert\text{-}BuO)_3Al$ in 32 cc. abs. benzene was refluxed overnight, treated with dil. H_2SO_4 and ether. The washed and dried ether layer gave 350 mg. of oily, yellow crystals. Chromatographic purification in benzene and recrystn. from MeOH yielded *Me 4,17-pregnadien-3-one-21-carboxylate*, $C_{22}H_{30}O_3$, m. 151–2°, $[\alpha]_D$ 80 ± 1° (*c* 1.00 in dioxane), no yellow color with $C(NO_2)_4$. The shift of the double bond is also apparent in the absorption curve. Partial reduction of 4.00 g. **III** in 200 cc. abs. alc. in the presence of 400 mg. of prereduced PtO_2 with 265 cc. H (calcd. 267 cc. for 1 mol.), chromatographing the product in benzene-hexane (1:4) and recrystn. of the crude main fraction (3.5 g.) from hexane gave *Me 3-acetoxy-5-pregnene-21-carboxylate* (**V**), $C_{24}H_{36}O_4$, m. 128·9°, $[\alpha]_D$ −57 ± 1° (*c* 1.00 in $CHCl_3$). The constitution of **V** is shown by the lack of any appreciable absorption above 220 mμ, as well as by its oxidation with $(tert\text{-}BuO)_3Al$ to *Me 4-pregnen-3-one-21-carboxylate*, $C_{22}H_{32}O_3$, m. 146–7°, $[\alpha]_D$ 84 ± 1° (*c* 0.991 in dioxane), no color with $C(NO_2)_4$. Partial reduction of **III** gave, as a by-product, the fully satd. *Me 3-acetoxyallopregnane-21-carboxylate*, $C_{24}H_{38}O_4$, m. 150–1°, $[\alpha]_D$ 0 ± 1° (*c* 1.00 in dioxane), also formed by reduction of **III** in AcOH in the presence of prereduced PtO_2 with 2 mols. H. Total sapon. of **V** by refluxing with 5% KOH in MeOH for 5 hrs., acidification, sublimation and crystn. from Et_2O-MeOH gave *3-hydroxy-5-pregnene-21-carboxylic acid*, $C_{21}H_{32}O_3$, m. 241–2°, $[\alpha]_D$ −56.4 ± 1° (*c* 0.985 in dioxane); *Me ester*, m. 132–3°, $[\alpha]_D$ −63.5° ± 1° (*c* 0.977 in dioxane), acetylated by Ac_2O in cold pyridine to **V**. **LVI. Conversion of 17-ethinyl-5-androstene-3,17-diol into progesterone.** M. W. Goldberg and R. Aeschbacher. *Ibid.* 1185–8.—Previous hydrogenations of the acetylenic linkage of 17-hydroxy-17-ethinyl derivs. of the androstane and androstene series have been accompanied by rearrangement of the C skeleton of the starting materials. Hydrogenation of 17-ethinyl-5-androstene-3,17-diol (**I**) has been accomplished without rearrangement so that the main product of the reaction is *5,16-pregnadien-3-ol-20-one* (**II**). A mixt. of 2 g. **I** and 4.1 g. $Hg(NHAc)_2$ was refluxed in 40 cc. abs. alc. for 20 hrs. and the soln. was satd. with H_2S. After concn. *in vacuo* the residue was exhaustively extd. with ether. The ext. was shaken out with H_2O, dried over Na_2SO_4 and evapd. to dryness. The product was taken up in acetone and filtered through a 40-g. Al_2O_3 column and ultimately eluted with Et_2O. The crude eluate (1.3 g.) was recrystd. from MeOH, yielding **II**, $C_{21}H_{30}O_2$, m. 211–13° (all m. ps. cor.); *Ac deriv.*, m. 175–7°, $[\alpha]_D$ −30.1 ± 1.5° (*c* 0.91 in 95% alc.); *oxime*, m. 219–20° (decompn.). **II** (200 mg.) was reduced in the presence of a Raney Ni catalyst to 5-pregnen-3-ol-20-one, which was oxidized according to Oppenauer to progesterone, m. 127° (after recrystn. from MeOH), $[\alpha]_D$ 185.3 ± 2.5° (*c* 0.68 in 95% alc.). At present, the mechanism of the formation of **II** from **I** by the action of $Hg(NHAc)_2$ is not understood. **LVII. Addition of aniline to 17-ethinyl-5-androstene-3,17-diol.** *Ibid.* 1188–90.—Previous to the publication of Loritsch and Vogt (*C. A.* **33**, 6236[1]) on the addn. of $PhNH_2$ and PhNHEt to 1-heptyne or 3-octyne in the presence of HgO or BF_3, a simple method of adding $PhNH_2$ to 17-ethinyl-5-androstene-3,17-diol (**I**) and its diacetate (**II**) had been worked out. A mixt. of 400 mg. **I** and 80 mg. $HgCl_2$ in 4 cc. of pure $PhNH_2$ was warmed at 60–70° for 20 hrs. and the excess $PhNH_2$ was steam-distd. from the brown crude reaction product. Recrystn. from dil. MeOH yielded 300 mg. of pure colorless *3,17-dihydroxy-5-pregnen-20-one anil* (**III**), $C_{27}H_{37}NO_2$, m. 190–2°, $[\alpha]_D$ −197.5 ± 2° (*c* 1.23 in $CHCl_3$). Oxidation according to Oppenauer by refluxing 100 mg. **II** and 500 mg. $(tert\text{-}BuO)_3Al$ in 4 cc. of dry acetone and 10 cc. benzene for 15 hrs. under reflux, chromatographing the crude oxidation product in benzene and recrystg. the eluate from 95% alc. gave 70 mg. of *3-keto-17-hydroxy-4-pregnen-20-one anil*, $C_{27}H_{35}NO_2$, m. 221–3°, $[\alpha]_D$ −19 ± 1° (*c* 1.00 in $CHCl_3$). Similarly the addn. of $PhNH_2$ to **II** and recrystn. of the addn. product from dil. EtOH gave *3,17-diacetoxy-5-pregnen-20-one anil*, $C_{31}H_{41}NO_4$, m. 207–9°, $[\alpha]_D$ −155 ± 2° (*c* 0.445 in $CHCl_3$). The constitution of the anils is not yet firmly established. **LVIII. Conversion of 17-ethinylandrostene-3,17-diol into pregnadien-3-ol.** L. Ruzicka, M. W. Goldberg and E. Hardegger. *Ibid.* 1294–1300.—The conversion of 17-

ethinyl-5-androstene-3,17-diol (I) by addn. of 1 mol. H to the acetylene group and consequent reductive cleavage of the OH group in the 17-position should give either 5,20-pregnadien-3-ol (II) or the corresponding 17-iso compd., both of interest for synthetical expts. in the pregnene series. I (942 mg.) in 55 cc. abs. alc. was added in 15 mins. to a well-stirred suspension of 27 g. Na in 120 cc. of boiling xylene. Further addns. of 60 cc. xylene and 16 cc. alc. were made and the clear soln. was cooled, dild. with 60 cc. of 96% alc. and 400 cc. H_2O. The colorless xylene layer was dild. with ether. The ether ext. was dried and evapd. and the reaction product was acetylated with 1.5 cc. Ac_2O in 10 cc. pyridine at room temp. in 20 hrs. After evapn. to dryness *in vacuo*, the reaction product was extd. with ether and recrystd. from hexane, taken up in 60 cc. of benzene-hexane (1:2) and filtered through 40 g. Al_2O_3. Elution with 250 cc. benzene-hexane mixt. and recrystn. from EtOH gave 711 mg. of 2-cm. long needles of *acetate*, $C_{23}H_{34}O_2$, m. 143–4°, $[\alpha]_D$ −70.3 ± 0.3° (*c* 5 in $CHCl_3$), sapond. by boiling for 2 hrs. with 0.1 *N* KOH in MeOH and recrystd. from alc. or ether to spears or needles of *pregnadien-3-ol* (III), $C_{21}H_{32}O$, m. 132–3°, $[\alpha]_D$ −74 ± 1° (*c* 1 in $CHCl_3$). Oxidation of 204 mg. III according to Oppenauer by boiling for 14 hrs. with 500 mg. of (*tert*-BuO)$_3$Al in 15 cc. benzene and 12 cc. acetone and working up by extg. with ether, chromatographing in hexane and crystg. from MeOH gave 179 mg. of pure *pregnadien-3-one* (IV), $C_{21}H_{30}O$, m. 142–3°, $[\alpha]_D$ 117.5 ± 1° (*c* 1 in $CHCl_3$), not seemingly identical with 4,17-pregnadien-3-one, m. 135° (*C. A.* **30**, 4509[2]). Catalytic reduction of III (500 mg.) in 30 cc. alc. and 60 cc. AcOH in the presence of 200 mg. of prereduced PtO_2 for 30 mins. and crystn. from alc. gave *allopregnan-3-ol* (V), $C_{21}H_{36}O$, m. 137.8°, $[\alpha]_D$ 16 ± 1° (*c* 1 in $CHCl_3$); *acetate*, m. 115–16°. Oxidation of 400 mg. V in 20 cc. AcOH with 230 mg. CrO_3 in 4 cc. AcOH and 1 cc. H_2O for 4 hrs. at room temp. and recrystn. of the crude gelatinous product from alc. produced *allopregnan-3-one* (VI), $C_{21}H_{34}O$, m. 116–17°; *semicarbazone*, m. 230° (decompn.); *hydrazone* (VII), m. 226° (decompn.). Heating 100 mg. VII, 0.2 cc. $H_2NNH_2.H_2O$ and 180 mg. Na in 2.5 cc. abs. alc. for 8 hrs. in a sealed tube at 200° and recrystg. the product from $CHCl_3$ and MeOH yielded 89 mg. of allopregnane, $C_{21}H_{36}$, m. 84–5°, $[\alpha]_D$ 18.0 ± 0.7° (*c* 1.388 in $CHCl_3$), identical with a sample prepd. from 3-hydroxy-21-acetoxy-5-pregnen-20-one by Steiger and Reichstein (*C. A.* **32**, 4996[8]). Both V and III were pptd. with digitonin, as was expected since the steric arrangement of the OH group at position 3 must be the same as in cholesterol (trans or β). Consequently III is a pregnadien-3(β)-ol with a double linkage in the 5,6-position but with the other in the 20,21-, 17,20- or even the 16,17-position. The possibility of a semicyclic position with cis-trans isomerism is not excluded. C. R. Addinall

7-Keto-3-hydroxy-5-etiocholenic acid and related compounds. T. Reichstein and H. G. Fuchs. *Helv. Chim. Acta* **22**, 1160–70(1939).—Oxidation of cholesteryl acetate with CrO_3 according to the method of Mauthner and Suida (*Monatsh.* **17**, 579(1896)) gave 7-ketocholesteryl acetate. This method has been used in the prepn. of 3,7-dihydroxyetioallocholanic acid (I) by the oxidation of Me 3(β)-acetoxyetio-5-cholenate (II). A mixt. of 5 g. II, m. 152–4° (all m. ps. cor.), in 50 cc. AcOH with 4 g. CrO_3 in 2.8 cc. H_2O and 8 cc. AcOH was warmed at 55° for 3 hrs. and evapd. to dryness at 30° *in vacuo*. The residue was taken up in H_2O and extd. with Et_2O. The washed and dried ext. was concd. and dild. with pentane, yielding 1.084 g. of colorless leaflets of *Me 7-keto-3(β)-acetoxyetio-5-cholenate* (III), $C_{28}H_{32}O_5$, m. 182–6°, $[\alpha]_D^{25}$ −74.8 ± 2°, $[\alpha]_{5461}^{25}$ −89.7 ± 3° (*c* 1.471 in acetone), together with a lower-melting mixt. which was taken up in benzene, treated with a 4-fold amt. of pentane and adsorbed on Al_2O_3. Elution with benzene-pentane (1:4 and 2:3) gave II. Elution with benzene-pentane (1:1) yielded *Me 7-ketoetio-3,5-choladienate*, $C_{21}H_{28}O_3$, m. 197–9°, crystg. from Et_2O-pentane, absorption max. 279 mμ, also formed by boiling 53 mg. III with 4 cc. of *N* HCl in MeOH for 15 min., evapg. to dryness, extg. with Et_2O and purifying by chromatographing in benzene-pentane. Catalytic reduction of 200 mg. III in 10 cc. AcOH in the presence of 100 mg. of prereduced PtO_2 for 4 hrs. with 24.1 cc. H gave a mixt. of *Me 3(β)-acetoxy-7(α and β)-hydroxyetioallocholanate* (IV), m. 118–33°, oxidized by CrO_3 in AcOH for 16 hrs. at 20° to yield *Me 3(β)-acetoxy-7-ketoetioallocholanate*, $C_{23}H_{34}O_5$, m. 176–9°. To sep. the 2 forms present in IV, 500 mg. of the mixt. in 6 cc. pyridine was warmed at 70–80° for 4 hrs. with 4 cc. Ac_2O. The mixt. was evapd. and extd. with Et_2O. The concd. ext. was dild. with pentane and, after standing for many days, yielded colorless frond-like needles of *Me 3(β), 7(α)-diacetoxyetioallocholanate* (V), $C_{25}H_{38}O_6$, m. 147–9°, $[\alpha]_D^{25}$ 64.1 ± 6°, $[\alpha]_{5461}^{25}$ 77.7 ± 6° (*c* 0.515 in acetone). The residue (350 mg.) from the mother-liquor was taken up in 2 cc. benzene, dild. with 8 cc. pentane and filtered through a 10-g. Al_2O_3 column. Washing with pentane, then with benzene-pentane (1:4) gave the *7(β) ester* (Va), m. 159–62°, $[\alpha]_D^{25}$ −3.1 ± 1°, $[\alpha]_{5461}^{25}$ −2.30 ± 1.5° (*c* 2.598 in acetone). Sapon. of 420 mg. V by refluxing with 0.8 g. KOH in 0.8 cc. H_2O and 20 cc. MeOH for 3 hrs., evapn., shaking out with Et_2O and acidification with HCl to Congo-red reaction yielded quantitatively *3(β),7(α)-dihydroxyetioallocholanic acid* (VI), m. 252–7° (decompn.); *Me ester* (VII) (by esterification with CH_2N_2), m. 194–7°. Acetylation of 361 mg. of crude VI with 2 cc. Ac_2O in 5 cc. of abs. pyridine for 2 hrs. on the steam bath gave fine colorless needles of *3(β),7(α)-diacetoxyetioallocholanic acid*, $C_{24}H_{36}O_6$, m. 237–41°. Similarly, sapon. of Va gave 3(β),7(β)-dihydroxyetioallocholanic acid (VIII), m. 230°; *Me ester* (IX), m. 224–9°. Oxidation of VII and IX with CrO_3 in AcOH gave the same *Me 3,7-diketoetioallocholanate* (X), $C_{21}H_{30}O_4$, m. 194–7°. Clemmensen reduction of 55 mg. X in 5.5 cc. AcOH and 7 cc. concd. HCl in the presence of 3 g. of amalgamated flowers of Zn and a slow stream of dry HCl for 2 hrs. with a further addn. of 2 g. of amalgamated Zn turnings and heating on the steam bath for 3 hrs., followed by extn. with pentane and sapon. gave etioallocholanic acid, m. 228–30°, characterized by the Me ester, m. 143–4° (Me etiocholanate, m. 99°). C. R. A.

System: butyl Mg bromide–$MgBr_2$–Et_2O (Doering, Noller) **2**. Absorption spectrum of hypericin (Pace, Mackinney) **3**. Raman effect in org. chemistry (Burgel, Pio) **3**. Lengths of links of unsatd. hydrocarbon mols. (Coulson) **3**. Chain length and chain-ending processes in AcH decompn. (Burton, *et al.*) **2**. Mechanism of oxidation of org. compds. by means of selenious anhydride (Mel'nikov, Rokitskaya) **2**. Interfacial activity of short-chain isomers (Addison) **2**.

Branched-chain paraffins. Gerardus H. Visser (to Shell Development Co.). Can. 384,905, Oct. 31, 1939. Isobutane is treated with C_3H_6 or butylene in the presence of H_2SO_4 of a concn. of about 90–100% at about −10 to 30°, the hydrocarbon product sepd. and distd. to sep. the fraction b. about 60–160°.

Diolefins. Aristid V. Grosse (to Universal Oil Products Co.). U. S. 2,178,584, Nov. 7. For converting monoolefins having less than 6 C atoms in straight chain arrangement into diolefins, the mono-olefin, e. g., C_4H_8, for the production of 1,3-butadiene, is subjected under dehydrogenating conditions (suitably for a short time at a temp. of 600° under 0.25 atm. pressure) to the action of a solid catalyst comprising a Cr, Mo or W compd., such as Cr_2O_3 on activated alumina.

Diolefins. Jacque C. Morrell (to Universal Oil Products Co.). U. S. 2,178,601, Nov. 7. For converting monoolefins having less than 6 C atoms in straight chain arrangement, such as *n*-butenes, into diolefins, treatment under dehydrogenating conditions (suitably for 0.5 sec. at 610° under 0.25 atm. pressure) is effected in the presence of a catalyst contg. a Ti, Zr, Ce, Hf or Th compd. such as TiO_2 on activated alumina. U. S. 2,178,602 (Jacque C. Morrell and Aristid V. Grosse, joint inventors) relates to the like use of catalysts contg. V, Cb or Ta compds. such as their oxides.

Products of reaction of hydrogen sulfide with olefins. Evan C. Williams and Clyve C. Allen (to Shell Development Co.). Can. 385,013, Nov. 7, 1939. Mercaptans, thio ethers or satd. hydrocarbons are prepd. by reaction of an olefin with H_2S at about 35–300° in the presence of a water-bonding agent, e. g., a carboxylic acid anhydride and a metal sulfide. 1

Olefin oxides. Karl Metzger and Leonid Andrussow (to I. G. Farbenind. A.-G.). U. S. 2,178,454, Oct. 31. See Brit. 507,538 (*C. A.* **34**, 447[1]). 2

Oxygenated organic compounds. William A. Bone and Dudley M. Newitt (to Canadian Industries Ltd.). Can. 384,682, Oct. 17, 1939. An aromatic hydrocarbon is treated, without catalyst, in the vapor phase with not more than a mol. equiv. of O under at least 10 atms. pressure. E. g., phenol is prepd. from C_6H_6 and O at 300–400°. Cf. *C. A.* **33**, 3810[7].

Stabilizing halogenated hydrocarbons. Irving E. Muskat and Lynn King (to Pittsburgh Plate Glass Co.). U. S. 2,178,695, Nov. 7. Normally unstable substantially satd. aliphatic hydrocarbons contg. substantial quantities of halogen, such as chlorinated naphtha, are brought into contact with concd. H_2SO_4 (suitably at 40–100° for 2–5 hrs.) to effect stabilization without decompn. of a major portion of the material. 3

Continuous reduction of aromatic nitro compounds. A. Ya. Vikman and V. S. Mukhanova. Russ. 52,006, Oct. 31, 1937. An aq. soln. or suspension of nitro compds. mixed with Fe chloride and HCl is continuously passed through a column filled with Fe shavings and heated to the reaction temp. 4

Hydrogenation of aliphatic hydrocarbon polymers containing tertiary carbon atoms. Samuel B. Thomas and Marion D. Taylor (to Shell Development Co.). Can. 385,774, Dec. 19, 1939. The liquid polymers are treated prelimnarily with a spent hydrogenation catalyst with avoidance of the formation of H_2S. E. g., liquid diisobutylene, contg. more than a crit. concn. of a catalyst-poisoning impurity, is passed with H through a min. of 3 converters connected in series, a Ni catalyst at least partially spent is maintained in the first converter at about 250–60° and an active Ni catalyst at about 195–200° in the subsequent converters. The operation is continued until the Ni catalyst in the first converter has nearly lost its power to remove S compds. from the diisobutylene, the first converter disconnected, the liquid diisobutylene and H are passed directly into the second converter, the temp. is increased to about 250–60° and the operation continued. 5

Unsaturated alcohols. Yu. S. Zal'kind and S. A. Zokis. Russ. 51,905, Oct. 31, 1937. Alcs. contg. at least one triple and two double bonds are prepd. from acetylene-bivinylmagnesium halides by the action of aldehydes or ketones. 6

Removing water from aqueous allyl alcohol. Harold R. Slagh (to Dow Chemical Co.). U. S. 2,179,059, Nov. 7. Methylene chloride is mixed with the aq. allyl alc., and water and methylene chloride are distd. from the mixt. 7

Catalytic formation of long-chain aldehydes from alcohols. Wilbur A. Lazier (to E. I. du Pont de Nemours & Co.). U. S. 2,178,761, Nov. 7. A process for the dehydrogenation of an aliphatic long-chain alc. such as dodecyl alc. to the corresponding aldehyde involves bringing the alc. into contact with a catalyst comprising a dehydrating metal such as Zn, Cu or Cd intimately assocd. with Cr_2O_3 at a pressure of less than 50 atm. (suitably about 1 atm.) and at a temp. of 50–450°, sufficiently high to cause evolution of H. 8

Ethers. Vladimir N. Ipatieff (to Universal Oil Products Co.). U. S. 2,179,092, Nov. 7. For the production of an ether such as ethyl ether, an olefin such as C_2H_4 is brought into contact with a dil. soln. of an acid contg. $ZnCl_2$ at 130–300° and under a pressure of 200–400 atm. 9

Producing ethers from olefins. Charles F. Oldershaw (to Shell Development Co.). U. S. 2,178,186, Oct. 31. A process of producing an ether, such as diisopropyl ether, from an olefin by bringing into contact a paraffin and olefin hydrocarbon mixt., such as one contg. C_3H_8, with an aq. olefin-hydrating inorg. acid catalyst such as 73% H_2SO_4 at a temp. such as 80–125° and under pressure, involves sepg. unreacted hydrocarbon material contg. ether from the reacted mixt., then extg. the remaining aq., ether-contg. soln. with a solvent for the ether which is incompletely miscible with the soln. under the extn. conditions, and treating the extd. olefin-hydrating inorg. acid catalyst with a further quantity of the paraffin-olefin hydrocarbon mixt. 10

***p*-Diazonium tertiary amines.** Walker M. Hinman and Walter G. Hollmann. U. S. 2,178,585, Nov. 7. A tertiary aromatic amine (such as ethylbenzylaniline for the production of an ethylbenzylaniline diazonium salt) which has a free para position and which has its N atom bearing one hydrocarbon radical having at least 3 C atoms and another hydrocarbon radical having at least one C atom, is subjected, in the form of an amine salt, such as the hydrochloride, in an acid medium, to the action of nitrous acid sufficient for the reaction of 1 mol. of tertiary amine with 4 mols. of nitrous acid, with resulting formation of a para diazonium salt of the tertiary amine. 11

Amino ketones. Ralph A. Jacobson (to E. I. du Pont de Nemours & Co.). U. S. 2,179,215, Nov. 7. For prepg. $(CH_3)_2CHCOC(CH_3)_2CH_2NHCH_3$ or other amino ketone, diisopropyl ketone or other compd. of the general formula $(CH_3)_2CHC(=O)R$ in which R represents a hydrocarbon radical is treated with CH_2O and with an amino-N-contg. compd. such as methylamine hydrochloride which contains a single N atom which is trivalent and attached to at least one H and otherwise joined only to hydrocarbon radicals, or a hydrohalide of such a compd. Various examples with details are given. 12

Polyglycerol esters. V. V. Dmitrov. Russ. 52,051, Oct. 31, 1937. Addn. to Russ. 23,393 (*C. A.* **26**, 1617). The method of Russ. 23,393 is extended to the prepn. of polyglycerol esters of fatty acids contg. 16 or more carbon atoms. 13

9-(Dialkylaminophenyl)acridines. N. S. Drozdov. Russ. 51,908, Oct. 31, 1937. 9-Chloroacridine is heated with dialkylaniline in the presence of $AlCl_3$. 14

Substituted phenols. Alois Zinke (to Beck, Koller & Co., Inc.) Can. 385,312, Nov. 28, 1939. Phenol is made to react with unsatd. constituents of cracked gasoline in the presence of a H halide and a chloride of Al, Fe or Zn. 15

Hydrohalogenation of vinylacetylene. Wallace H. Carothers and Arnold M. Collins (to E. I. du Pont de Nemours & Co.). U. S. 2,178,737, Nov. 7. Vinylacetylene is distributed in finely divided form in an aq. soln. of HCl or HBr and the addn. products formed are allowed to rise and form a liquid layer above the H halide soln. and are drawn off. 16

Salts of methylcholine ethers. Georg Roeder (to Merck & Co., Inc.). Can. 385,232, Nov. 21, 1939. An alkali metal salt of 1-dimethylamine-2-hydroxypropane is alkylated, e. g., with Me_2SO_4, and the product is further alkylated with an alkyl halide or sulfate. 17

Purifying alkyl sulfates. Egi V. Fasce and Emile C. Rolfs, Jr. (to Standard Oil Development Co.). U. S. 2,178,786, Nov. 7. A crude alkyl sulfate such as a crude alkyl sulfate mixt. contg. inorg. salts and water is treated with a substantially anhyd., water-sol. volatile org. liquid such as iso-PrOH which forms a const.-boiling mixt. with water and is vaporizable at a temp. below that at which the alkyl sulfate decomposes; a substantial portion of the added org. liquid is evapd. by heating, thus reducing the water content of the remaining alkyl sulfate compn., and inorg. salts are pptd. and sepd. 18

Vinyl chloride. V. P. Komarov, P. I. Pavlovich and B. S. Korotkevich. Russ. 51,962, Oct. 31, 1937. A portion of the reaction mixt. of dichloroethane and aq.-alc. NaOH is continuously injected into the reaction chamber, while the other part of the mixt. is continuously filtered into the chamber through solid NaOH. The vapors of vinyl chloride are continuously discharged from the reactor through a bubble tower used in which alc. and dichloroethane are removed. 19

Polymerizing vinyl chloride mixtures. Werner Heuer (to I. G. Farbenind. A.-G.). U. S. 2,179,040, Nov. 7. Gaseous vinyl chloride is polymerized (while maintained in the gaseous state) together with a normally liquid monomeric compd. of copolymerizable character such as vinyl acetate in intimate contact with an "indifferent" liquid such as water which is incapable of dissolving the monomeric compds. and which contains a polymerization catalyst such as K persulfate (suitably at 50–60°). 1

Polymers of isobutylene. Raphael Rosen and Robert M. Thomas (to Standard Oil Development Co.). U. S. 2,178,808, Nov. 7. An arrangement of app. is described, and a process for prepg. polymers of isobutylene, which comprises selectively depolymerizing a mixt. of polymers of isobutylene exclusively, polymers of normal butylene and copolymers of normal butylene with isobutylene, the mixt. consisting substantially of trimers of the butylenes, by passing the mixt. rapidly through a heated reaction zone at a depolymerization temp. of the order of 340–510° and providing sufficient time for depolymerization substantially only of the polymers of isobutylene exclusively, whereby the depolymerized reaction product is substantially pure isobutylene, sepg. the isobutylene from the undepolymerized polymers, and repolymerizing the sepd. isobutylene. 2

Heavy metal cyclic nitroso compounds. Edgar F. Rosenblatt (to Baker & Co.). U. S. 2,178,809, Nov. 7. Compds., various of which may be added to gasoline for improving its combustion, are produced by a method which may involve mixing a compd. of a heavy metal having at least one nitrite group, such as a Ag, Co, Ni, Cu or Cr compd., with an aromatic org. compd. having a reactive H, such as aniline, toluidine or naphthol, and adding an acid such as HOAc. 3

Dehydroacetic acid. Albert B. Boese, Jr. (to Carbide and Carbon Chemicals Ltd.). Can. 384,872, Oct. 31, 1939. Diketene is polymerized to dehydroacetic acid by slowly adding it to a volatile, inert solvent, e. g., C_6H_6, in the presence of a catalyst, e. g., pyridine. 4

Methacrylic acid. I. F. Markov. Russ. 52,085, Oct. 31, 1937. A mixt. of α- and β-chloroisobutyric acids is heated to boiling in the presence of activated C and hydroquinone; the methacrylic acid is distd. off as formed. 5

Methacrylic acid. I. F. Markov. Russ. 52,086, Oct. 31, 1937. Methacrylic acid is prepd. by passing a mixt. of α- and β-chloroisobutyric acids *in vacuo* over activated C at a temp. of 150–300° with or without the introduction of steam. 6

λ-Ketostearic acid and derivatives. Henry L. Cox (to Carbide and Carbon Chemicals Ltd.). Can. 385,794, Dec. 19, 1939. Processes are described for prepg. λ-ketostearic acid and its esters and salts.

Dehydrogenation of hydroxy carboxylic acids and their esters. Wilbur A. Lazier (to E. I. du Pont de Nemours & Co.). U. S. 2,178,760, Nov. 7. Materials such as hydrogenated castor oil, for the production of ketostearin, or butyl or ethyl 12-hydroxystearate, for the production of butyl or ethyl 12-ketostearate, are heated with a Ni catalyst prepd. by the H reduction of an O-contg. Ni compd. such as Ni chromite at 250–500°, on a carrier such as kieselguhr, use of various other catalysts for similar reactions being mentioned. 7

Removal of chlorides from solutions of amino acids. Louis Gerber (to Corn Products Refining Co.). U. S. 2,178,510, Oct. 31. A soln. of amino acids such as one produced by treating corn gluten with HCl and NaOH and which also contains chlorides such as NaCl, KCl and NH_4Cl is treated by pasing HCl gas through the soln. at a temp. of about 38–50°. 8

Use of ketene in preparing anhydrides. Anthony H. Gleason (to Standard Oil Development Co.). U. S. 2,178,752, Nov. 7. Mixed anhydrides are produced by treating ketene with an org. carboxylic acid such as tartaric, lactic or citric acid or glycine or furoic acid. 9

Tetrachloroethylene. Georg Basel and Erich Schaeffer (to Alex. Wacker Ges. für elektrochemische Industrie G. m. b. H.). U. S. 2,178,622, Nov. 7. Reaction is effected between gaseous hexachloroethane and C_2H_2 at 200–400° in the presence of contact surfaces such as activated C. Cf. *C. A.* **33**, 2151[3].

1,1,1-Trichloropropane. Arthur A. Levine and Oliver W. Cass (to E. I. du Pont de Nemours & Co.). U. S. 2,179,218, Nov. 7. An isomer of trichloropropane, b. 106–7°, and suitable for use as a solvent of oil and grease, is prepd. by reaction of HCl with 1,1-dichloro-1-propene (suitably in the presence of $AlCl_3$ at 5–10°).

Pentaerythritol. Joseph A. Wyler (to Trojan Powder Co.). U. S. 2,170,624, Aug. 22. Pentaerythritol is prepd. by alk. condensation of AcH with CH_2O substantially free from MeOH, in aq. soln. Cf. *C. A.* **33**, 5188[9].

Conversion of normal butene to isobutene. Adrianus J. van Peski and Hermanus F. J. Lorang (to Shell Development Co.). Can. 384,317, Sept. 26, 1939. A gaseous hydrocarbon mixt. contg. about 50% each of butane and normal butenes is brought into contact with a solid catalyst comprising a calcined mixt. of a P oxy-acid and a siliceous material at about 275–325° for about 2–50 sec. Polymerization of the butenes is substantially obviated.

Isolation of leucine and tyrosine from corn grits. Arthur M. Mark (to Corn Products Refining Co.). U. S. 2,178,210, Oct. 31. A process of treating a soln. of amino acids produced by the acid hydrolysis of corn gluten for elimination and recovery of glutamic acid, then adjusting the temp. and d. of the soln. and bringing it to a pH of 0.9–1.0 to effect pptn. of leucine, sepg. the ppt., adjusting the temp. and d. of the soln. and bringing it to a pH of 2.4–3.4 to effect pptn. of tyrosine.

Terpineol. Donald H. Sheffield (to Hercules Powder Co.). U. S. 2,178,349, Oct. 31. A process of producing terpineol from pinene involves treating pinene with a dil. aq. polybasic noncarboxylic acid such as H_2SO_4 or a monoaryl or monoalkyl deriv. of such an acid, such as benzenesulfonic acid, in the presence of an org. liquid such as acetone which is miscible with both the pinene and the acid and nonreactive therewith (suitably at a temp. of 35–45°).

Bis(aminophenyl) sulfone. Chinoin Gyógyszer- és Vegyészeti Termékek Gyára R. T. (Kereszty és Wolf). Hung. 121,910, Nov. 2, 1939. Nitrophenyl aminophenyl sulfide is acetylated to protect the NH_2 group, oxidized by $KMnO_4$ in glacial acetic acid, and the nitro group reduced in a soln. contg. dil. mineral acids in presence of Pd catalyst.

Dimethyl-*p*-phenylenediamine. M. E. Kats. Russ. 52,076, Oct. 31, 1937. Nitrosodimethylaniline is reduced with alkali sulfide in aq. soln. in the presence of Al salts.

1,2-Anthraquinonenaphthacridone. V. A. Titkov. Russ. 52,008, Oct. 31, 1937. 1,2-Anthraquinonenaphthacridone is prepd. by treating β-naphthoyl-1-aminoanthraquinone-2-carboxylic acid in a solvent with benzotrichloride.

Bivinyl. D. V. Tishchenko, A. N. Churbakov and V. N. Ryazantsev. Russ. 52,023, Oct. 31, 1937. Addn. to Russ. 46,570 (*C. A.* **33**, 3399[9]). By the method described in Russ. 46,570, bivinyl is prepd. from 1,2- 1,3- or 1,4-dichlorobutane or from their mixts. with 1,1- and 2,3-dichlorobutane.

2-Chloro-1,3-butadiene. D. V. Tishchenko and A. N. Churbakov. Russ. 51,994, Oct. 31, 1937. Addn. to Russ. 46,570 (*C. A.* **33**, 3399[9]). 2,2,3-Trichlorobutane is passed over a catalyst consisting of a mixt. of $MgCl_2$ and $MgSO_4$ on a carrier.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

ARTHUR W. DOX

Melanin and its precursors. I. W. L. C. Veer. *Rec. trav. chim.* **58**, 949–55(1939)(in English).—Raper (*C. A.* **22**, 95) has shown that the oxidation of tyrosine (I) by tyrosinase (II) leads to the formation of dopa, 5,6-dihydroxyindole and 5,6-dihydroxyindole-2-carboxylic acid (III). According to his hypothesis the quinone of III is the red-colored precursor of melanin obtained by the oxidation of tyrosine with tyrosinase. The isolation of the red substance (IV) and the detn. of its structure seems to be of importance since Jacobs (*C. A.* **31**, 7108[6]) considered it an antipernicious anemia principle; Breijer (*Beitr. path. Anat.* **102**, 412(1939)) suggests that premelanin of the skin-epidermis acts in blood formation; and Szent-Györgyi postulates that orthoquinones may function in biol. oxidations. Although IV does not react with $PhNH_2$ it has been shown that it reacts with the more reactive $PhNHNH_2$ and substituted derivs. such as $4\text{-}O_2N.C_6H_4\text{-}NHNH_2$ and $4\text{-}BrC_6H_4NHNH_2$ forming monohydrazones probably by reaction with the CO group in the 5-position. I (1 g.) in 1 l. H_2O at 30° was treated with 100 cc. II (prepd. from meal worms in 0.02 *N* NH_4OH and enough 1% AcOH to bring the pH to 6.0–6.5. Oxygen was bubbled through the soln. for 5 min. and the stoppered vessel was shaken from time to time during a 30-min. standing. The oxidation was repeated and after about 2 hrs., 10–15 cc. of 1% AcOH was added. The dark ppt. (a compd. of I and II) was filtered off giving a pomegranate-red soln. of IV, insol. in Et_2O, $CHCl_3$, CCl_4, petr. ether, benzene, toluene, BuOH and *iso*-BuOH. The soln. from 1 g. I was treated with 1.2 g. $PhNHNH_2$ in 15 cc. of 30% AcOH yielding a red-brown powder of the *monophenylhydrazone hydrate*, $C_{15}H_{13}N_3O_3.H_2O$, m. about 168° (decompn.). Similarly were prepd. the corresponding mono-*p*-nitrophenylhydrazone hydrate, $C_{15}H_{12}N_4O_5.H_2O$, m. about 190° (decompn.), hydrolyzed on boiling with dil. H_2SO_4; and the *p*-bromophenylhydrazone dihydrate, $C_{15}H_{12}BrN_3O_3.2H_2O$, m. about 174° (decompn.). No addn. with 2,4-$(O_2N)_2C_6H_3NHNH_2$ according to the method of Brady (*C. A.* **25**, 3319) took place. C. R. Addinall

The pH optimum of fumarase. C. N. Ionescu, N. Stanciu and V. Rădulescu. *Ber.* **72B**, 1949–52(1939).—Although fumarase catalyzes reversibly the reaction: fumaric acid ⇌ malic acid, the pH optimum varies according to the direction of the reaction. For the reaction fumaric acid → malic, it is 7.16; for malic acid → fumaric, 8.33. This difference is explained by assuming that the change in pH value (1) alters the degree of dispersion of the enzyme, thus increasing or decreasing the active surface; and (2) influences the degree of dissocn. of the substrate. E. S. G. Barron

Nonosseous origins of serum phosphatase. Aaron Bodansky. *Proc. Soc. Exptl. Biol. Med.* **42**, 800–4 (1939).—Preliminary. L. E. Gilson

The biologic decomposition and synthesis of amino acids. Wilhelm Franke. *Angew. Chem.* **52**, 695–8, 703–8(1939).—A comprehensive summary covering earlier work (up to 1930), the discovery of amino acid oxyhydrases, the glutamic acid dehydrogenase, amine migration, carboxylic amine formation as a side reaction of the biol. amino acid decompn., the amino acid dismutation of anaërobic bacilli, and pathogenic and pathol. protein metabolism. 71 references. Karl Kammermeyer

Animal fat acid dehydrogenases and their coenzymes. I. O. St. A. Konrad Lang. *Z. physiol. Chem.* **261**, 240–8 (1939).—Liver and muscle contain a fat acid dehydrogenase (Thunberg technique, cf. *C. A.* **32**, 5929[9]). The activity increases with the length of the fat acid chain whether with even or odd nos. of C. The pH optimum is at 8.0 and the enzyme is sensitive to NaCN but not to F^- or iodoacetate. The enzyme requires a coenzyme which is not identical with cozymase or with codehydrogenase II. The fat acid codehydrogenase is relatively less sensitive to heating with acids or alkalies than are the other coenzymes. To prep. an active ext., rub 2 rat livers to a pulp without sand and ext. 6 times with 75-cc. portions of ice water. The residue is then ground with sand and extd. with 50 cc. ice-cold 0.05 *M* phosphate buffer at pH 8. The coenzyme is obtained from an ice-water ext. of rabbit muscle, which is boiled, filtered and mixed with 10 cc. 10% HOAc and 40 cc. satd. $Pb(OAc)_2$ per l. The ppt. is washed and decompd. with Na_2SO_4 soln. and H_2SO_4, the filtrate from $PbSO_4$ made 1% in H_2SO_4 and 25% phosphotungstic acid added. The ppt. is decompd. with $Ba(OH)_2$. The filtrate is treated with $AgNO_3$ and NH_3 and the Ag ppt. decompd. with H_2S. The resultant soln. is dried over H_2SO_4 in vacuum, dissolved in a little water and the insol. material discarded. The residue is again evapd. *in vacuo*. Yield is 0.125–0.15 g./kg. of rabbit muscle. II. O. St. A. Konrad Lang and Hermann Mayer. *Ibid.* 249–53.—The fat acid dehydrogenase described above has little effect on unsatd. fat acids and appears to be specific for satd. higher fat acids. The products are shown to be unsatd. fat acids. The codehydrogenase is probably muscle adenylic acid. M. L.

Formation of thyroxine from diiodotyrosine. Paul von Mutzenbecher. *Z. physiol. Chem.* **261**, 253–6(1939); cf. *C. A.* **33**, 5421[5].—On incubating a soln. of 20 g. diiodotyrosine-$2H_2O$ in 425 cc. of 0.1 *N* NaOH for 14 days the pH changed from 8.8 to 8.4, 11% of the total I appeared as I and the liquid gave a yield of 40 mg. of K thyroxine. The formation of thyroxine under these conditions explains its formation from iodized proteins especially after alk. incubation. Milton Levy

The complete separation of alkaline kidney phosphatase into protein and prosthetic groups and its reactivation. II. D. Albers. *Z. physiol. Chem.* **261**, 269–72(1939); cf. *C. A.* **34**, 456[7].—Dialysis of alk. kidney phosphatase prepns. for 200 hrs. completely inactivates the prepn. Addn. of $MgCl_2$ does not reactivate the dialyzed prepn. but addn. of dialyzate restores about 20% of the original activity. Long periods of dialysis therefore destroy some of the apoenzyme. Milton Levy

Enzymic decomposition of *l*-dihydroxyphenylalanine (dopa) by liver and intestine. Peter Holtz, Alexander Reinhold and Karl Credner. *Z. physiol. Chem.* **261**, 278–86(1939); cf. *C. A.* **33**, 8629[3].—Liver and intestine contain an enzyme catalyzing the decarboxylation of *l*-dihydroxyphenylalanine (I) to hydroxytyramine (II) as shown by the pharmacol. activity (blood pressure increase) of the prepns. after adding I and by anaerobic liberation of CO_2. The decarboxylase is present in kidney and liver of guinea pigs, rabbits, pigs, sheep, goats and chickens but not in rats, mice, cows or frogs. It is present in the upper intestinal tracts of guinea pigs and not of the other animals, nor in the colon or rectum of guinea pigs. The enzyme does not act on *d*-I. It is inhibited by KCN. Oxidation of I in liver and intestinal exts. goes quantitatively through II finally producing dihydroxyphenylacetaldehyde. The latter substance lowers blood pressure. Milton Levy

Liquefaction of starch. A method for estimation of the liquefaction of starch paste. Karl Mayer. *Z. physiol. Chem.* **262**, 29–36(1939).—Starch which has been treated with an amt. of I_2 just insufficient to produce a blue color is resistant to saccharification but is still liquefied by enzymes. Thus, a 1% starch paste treated with 0.65 cc. of 0.01 *N* I_2 per 100 cc. is liquefied but no sugar appears on adding malt enzymes, nor is the I_2 color reaction changed. To est. the liquefying power of exts. prep. a starch paste substrate as previously described (*C. A.* **30**, 116[8]) and add the proper amt. of I_2. To 50 cc. of the substrate add 5 cc. of buffer (pH 5 which is optimal), warm to 37°, add 10 cc. of enzyme soln. at 37° and measure the time of flow at suitable intervals in an Ostwald viscometer. For 0 time use water instead of enzyme soln. Milton Levy

The influence of radiation with the quartz lamp on the group characteristics of red cells. H. Buchwald. *Z. Immunitäts.* **96**, 236–41(1939).—Radiation with ultraviolet rays for 8 or 15 hrs. may lower the titer of agglutination of red cells but does not completely destroy their group reactivity. Julian H. Lewis

The solubility of pancreatic amylase in some organic solvents. Junius Larsen and Chas. F. Poe. *J. Biol. Chem.* **132**, 129–33(1940).—The amylase prepns. used in the soly. detns. were samples of com. amylopsin prepd. from fresh pancreas. More active prepns. were not obtained when ordinary alcs., esters and ethers were used as solvents. Slightly more active material was extd. by ethylene glycol and its ether. Of all solvents tried satd. aq. acetamide was the most selective, bringing about a 3–4-fold increase in activity. A. P. Lothrop

Molecular weight of egg albumin. F. W. Bernhart. *J. Biol. Chem.* **132**, 189–93(1940).—Analyses of the tyrosine, tryptophan and phenylalanine content indicate a minimal mol. wt. of 18,400 for electrodialyzed, moisture-free egg albumin. Calcns. indicate the presence of 310 amino acids per mole of albumin, this result resting on the assumption that no unknown basic amino acids or N-contg. prosthetic groups are present. This no. of amino acids per mole approaches closely the value of 288 calcd. by Bergmann and Niemann (*C. A.* **31**, 4350[6]). A. P. Lothrop

The effect of Röntgen rays on the blood codehydrogenases I and II. Wm. B. Bean, Richard W. Vilter and Tom D. Spies. *Ann. Internal Med.* **13**, 783–6(1939).—Detns. of codehydrogenases I and II were made before and after x-radiation on 3 healthy persons, 2 cases of myelogenous leucemia and 3 pellagrins in remission. Ether-sol. pigments having the color of porphyrin in 25% HCl, similar to those found in pellagra, appeared in all cases 12 hrs. after irradiation and disappeared within 48 hrs. Nicotinic acid, administered before irradiation, prevented the development of pigments but not the decrease in the coenzyme content of the blood. In those cases which received no nicotinic acid the blood codehydrogenases decreased 60 to 90% within 12 hrs. after irradiation and returned to normal after 24 hrs. A no. of other oxidation-reduction enzyme systems may be affected by exposure to x-rays. John T. Myers

Statistical analysis of biological elementary reactions. P. Jordan. *Arch. ges. Virusforsch.* **1**, 171–214(1939).—Review with 81 references. J. Pinchack

The chemistry of the enzymes. H. Bruce Collier. *Can. J. Comp. Med.* **3**, 293–300(1939).—A discussion of recent advances, without bibliography. J. Pinchack

The function of thymonucleic acid in living cells. Einar Hammarsten. *J. Mt. Sinai Hosp., N. Y.* **6**, 115–25 (1939).—A lecture on the intermolecular properties of nucleic acids and their relation to chromosome structure. J. Pinchack

Some biological aspects of protein chemistry. Max Bergmann. *J. Mt. Sinai Hosp., N. Y.* **6**, 171–86(1939).—A lecture with 25 references. J. Pinchack

Infrared absorption spectra of chlorophyllous pigments in living cells and in extracellular states. E. Katz and E. C. Wassink. *Enzymologia* **7**, 97–112(1939)(in English). —When unicellular organisms are ground with fine carborundum powder cell-free systems can be prepd. which contain the photosynthetically active pigments connected with their bearers which are probably of protein nature. The exts. can be prepd. with distd. water, phosphate buffer, etc. Exts. of this type were prepd. from the green alga *Chlorella*, a strain of purple S bacteria and a member of the Athiorhodaceae, *Rhodospirillum rubrum*. The absorption spectra of the exts. in the red and infrared region resemble closely those of the living cells. The shape is practically unaltered but the position is altered slightly. The changes depend upon the mode of extn. Under the ultramicroscope the ext. shows distinct colloid particles. Exts. prepd. with distd. water have an isoelec. point at pH 3.7. Different gas phases (O, air, N, H in the presence of Pd, H_2S) did not influence the infrared absorption spectrum of the purple S bacteria. Strong light affected the colloidal exts. much less than it affected the org. exts. Heat influences the spectrum. A new max. arises, probably owing to pigment liberated from the protein bearer. Measurements were made of spectra of exts. of *Chlorella* and purple S bacteria with various org. solvents. From the relation of the band max. to n of the solvent a value for the band max. of sep. pigment mols. was extrapolated. In all cases the absorption max. of pigment exts. in org. solvents shows an appreciable shift to the shorter wave lengths, as compared with the absorption max. of the pigment in the intact cells. This shift is especially obvious in the case of the purple and green bacteria. Dried pigment from an alc. ext. of purple S bacteria shows the same position of the max. as the ext. itself, an indication that the difference between the max. in living cells and org. exts. cannot be due to differences in concn. of the pigment. Felix Saunders

Carotene oxidase. James B. Sumner and Alexander L. Dounce. *Enzymologia* **7**, 130–2(1939)(in English).—Carotene oxidase, which occurs in the soybean, adds gaseous O to the double bonds of carotenoids and unsatd. fats, forming peroxides. The pH for optimum activity is at about 6.5. The enzyme has a neg. temp. coeff. between 15 and 30°. Felix Saunders

Extraction of proteins and proteolytic enzymes from yeast. Harold H. Strain. *Enzymologia* **7**, 133–41(1939)(in English).—Proteins, proteolytic enzymes and peptide-splitting enzymes are readily extractable from ground fresh yeast and from ground dried yeast. Extn. of these compds. from yeast is dependent upon rupture of the cell walls. It does not depend upon measurable autolysis of the cell proteins. Proteolytic enzymes in the exts. appear to be bound to the proteins. Autolysis of yeast is not inhibited by oxidizing agents which inactivate proteases of the papain type. Autolysis of yeast exts., like that of yeast itself, is inhibited by H_2S. Concn. of yeast exts. does not prevent hydrolysis of the protein. Concn. of yeast autolyzates does not lead to synthesis of protein. Oxygenation of concd. yeast exts. and of yeast autolyzates does not increase their protein content. Complex reactions between alanine and glucose are accelerated by the presence of phosphates and alkalies. These reactions are accompanied by a decrease in free amino groups. They are not assocd. with a decrease in basic N. Reactions between sugars and amino compds. may complicate interpretation of reactions which take place in killed tissues. Felix Saunders

Preparation and properties of "alkaline" phosphatase I. R. Cloetens. *Enzymologia* **7**, 157–60(1939)(in French); cf. *C. A.* **33**, 6366[6].—A method is described for the prepn. of "alk." phosphatase. Mg increases its activity 30–50 times. In the presence of Mg and 0.01 *M* substrate, 0.01 *M* KCN has no effect when the time of hydrolysis is 1 hr. and the pH 9.0. At pH 5–6 the enzyme is inactive. Alk. phosphatase I is more stable in acid than alk. phosphatase II. At its optimum pH alk. phosphatase I is stabilized by Mg. It is markedly inhibited by 0.01 *M* KF. Felix Saunders

Chromatographic adsorption of the enzymes of the snail, Helix pomatia, which act on chitins. L. Zechmeister, G. Tóth and É. Vajda. *Enzymologia* **7**, 170–5(1939)(in German).—Hepatopancreas exts. of *H. pomatia* were chromatographed on bauxite and a chitinase and a chitobiase were sepd. The latter can be extd. more easily. In contrast to the corresponding enzymes of emulsin, no generally valid sequence in the Tswett column can be given. The juice acts vigorously on the β-phenyl-*N*-acetyl-*d*-glucosaminide, but much more weakly on the α-isomeride. These 2 enzymes were sepd. chromatographically. The β-phenyl-*N*-acetyl-*d*-glucosaminidase accompanies in this case the chitinase and not the chitobiase. Felix Saunders

Chromatographic adsorption of the enzymes of emulsin which act on chitins. L. Zechmeister and G. Tóth. *Enzymologia* **7**, 165–9(1939)(in German).—The enzymes occurring in emulsin (Merck) which act on chitin or its breakdown products were submitted to chromatographic analysis. The chitinase which shows a specific hydrolyzing

effect on chitin and still more on chitodextrin is not adsorbed by a suitable bauxite column. It is found in the filtrate while a second enzyme, the chitobiase, which breaks down only low-mol. substrates, remains in the adsorbate. Therefore emulsin must contain both a polysaccharase and an oligosaccharase. The chromatographic behavior of an enzyme which acts on β-phenyl-*N*-acetyl-*d*-glucosaminide clearly differentiates it from chitinase. The corresponding α-compd. is neither attacked by the crude emulsin nor by its fractions, prepd. by chromatographic adsorption. Felix Saunders

Amylase determination in barley. K. Myrbäck and B. Örtenblad. *Enzymologia* **7**, 176–81(1939)(in German).—The β-amylase of barley is partly bound to an insol. protein and is inactive in this form. It can be freed by proteolytic enzymes and thus activated. The total amt. of amylase in barley can be detd. after treatment with papain. Felix Saunders

Oxido-reduction processes in the inhibition and activation of amylase. Józef Janicki. *Enzymologia* **7**, 182–92 (1939)(in German).—The activation of amylase by H_2S consists almost entirely of a removal of inhibiting substances. Ascorbic acid will strongly inhibit barley amylase. The inhibition is assocd. with a dehydrogenation of the ascorbic acid. It is reversible and can be prevented by H_2S and other reducing substances. The dehydrogenation of the ascorbic acid and, therefore, the inhibition of the amylase is strongly accelerated by traces of Cu so that it is important to use very carefully purified water. The dehydrogenation of ascorbic acid and inhibition of amylase also take place in starch-buffer soln. If the reoxidation is accelerated by the addn. of water contg. traces of Cu, then the reversibility of the activation brought about by H_2S can be demonstrated. Ascorbic acid also inhibits α-amylase. This inhibition results from an oxidation of ascorbic acid and can be prevented by H_2S. The disappearance of the α-amylase at the end of the ripening period of the barley cannot be ascribed entirely to the oxidation of ascorbic acid since the dextrinizing action and liquefying power of the amylase is not restored by H_2S. Felix Saunders

The inhibiting effect of hydrocyanic acid upon cell oxidase and peroxidase. Lawrence S. Malowan. *Enzymologia* **7**, 193–4(1939)(in English).—2,6-Dichlorophenolindophenol in its reduced form is an indicator for peroxidase. The colorless soln. changes to a deep red when horseradish ext. and 0.02 *N* H_2O_2 are added. The reaction is sensitive to HCN in concns. greater than $^1/_{600}$ *N*. Felix Saunders

Reputed synthesis of protein by aeration of protein-proteinase digests. II. K. Linderstrøm-Lang and G. Johansen. *Enzymologia* **7**, 239–40(1939)(in English); cf. *C. A.* **33**, 8643².—No protein synthesis could be demonstrated. Felix Saunders

Oxygenation of papain digests of wool. Formation of compounds insoluble in trichloroacetic acid. Harold H. Strain and K. Linderstrøm-Lang. *Enzymologia* **7**, 241–4 (1939)(in English).—A decrease in N sol. in Cl_3CCO_2H occurs only in strongly concd. digests exposed to the air. The disappearance of substances sol. in Cl_3CCO_2H is not accompanied by a decrease in amino groups. All the sulfhydryl groups, which are titrated to a slight extent in alc., disappear in air; hence a slight decrease in carboxyl groups is observed. There is no indication for the synthesis of peptide bonds by aeration. Felix Saunders

Characteristics of enzymic and autoclaved hydrolyzates of gelatin. N. I. Gavrilov and V. S. Balabukha-Poptsova. *Enzymologia* **7**, 245–55(1939)(in French).—During hydrolysis of proteins in the autoclave, and probably by enzymes, there is not only the process of hydrolysis and liberation of native anhydrides, but also cyclization, and perhaps rupture of rings. Felix Saunders

Specific enzyme deaminizing free and combined adenylic acid. Henry Borsook and Jacob W. Dubnoff. *Enzymologia* **7**, 256(1939)(in English).—An ext. of *Aspergillus wentii* contains a mixt. of peptidases which completely hydrolyzes Witte's peptone in 24 hrs. NH_3 is also liberated by this ext. The ext. does not liberate NH_3 from 0.01 *M* solns. of adenine, *dl*-alanine, allantoin, alloxan, *d*-asparagine, *d*-aspartic acid, creatine, *l*-cysteine, *l*-cystine, guanidine, guanine, glycine, glycocyamine, *d*-glutamic acid, hippuric acid, hypoxanthine, *l*-leucylglycine, *d*-lysine, *dl*-methionine, *d*-ornithine, *dl*-phenylalanine, *l*-proline, sarcosine, *dl*-serine, *l*-tryptophan, *l*-tyrosine, *d*-valine, xanthine, uracil, urea and uric acid but does liberate NH_3 from adenylic acid, adenylic acid pyrophosphate and nucleic acid. Felix Saunders

Crystalline constituents of the nonsaponifiable fraction of bone marrow. Harry N. Holmes and Ruth E. Corbet. *Science* **90**, 518(1939).—Four cryst. substances have been isolated from the nonsaponifiable fraction of whole bone marrow. One of the substances was cholesterol. The others have the following properties: (I) C 73.6%, H 13.4%, m. 66–7°, mol. wt. 296 (Rieche method, cf. *C. A.* **27**, 633), *benzoate* m. 35–6°, *acetate* m. 34–5°. (II) C 76.9%, H 13.0%, m. 61–3°, *benzoate* m. 137–8°, *acetate* m. 37–8°, mol. wt. 268. (III) C 82.2%, H 12.1%, m. 124° (not sharp), *benzoate* m. 123–5°. This substance formed a *digitonide*. Felix Saunders

Decomposition of hydrogen peroxide by catalase. Joseph Weiss and H. Weil-Malherbe. *Nature* **144**, 866 (1939).—Discussion. E. D. Walter

Synthesis of coenzymes I and II. S. P. Vilter, R. W. Vilter and T. D. Spies. *Nature* **144**, 943(1939); cf. *C. A.* **33**, 5482⁷.—The concn. of coenzymes I and II in normal human blood and leucemic blood is doubled after incubation with nicotinic acid amide. Washed erythrocytes, however, from normal blood and leucemic blood, resuspended in saline or serum, show no increase in the concn. of coenzymes I and II after incubation under similar conditions. Their concn. is greatly increased in a suspension of white cells of the lymphoid and myeloid series after incubation with nicotinic acid amide. E. D. Walter

Mucolytic enzyme in testis extracts. E. Chain and E. S. Duthie. *Nature* **144**, 977–8(1939).—An enzyme was obtained in "spreading factor" exts. from testis which hydrolyzed a polysaccharide in synovial mucin with liberation of reducing sugars. The possible identity of this enzyme with "spreading factor" is discussed. E. D. Walter

Isolation of a catalytically active flavoprotein from liver. V. Subrahmanyan, D. E. Green and A. H. Gordon. *Nature* **144**, 1016(1939).—A flavoprotein was obtained from pig liver which catalyzes the oxidation of aldehydes to their corresponding acids. This enzyme contains flavinadenine dinucleotide. E. D. Walter

Nicotinic acid. B. W. Fairbanks and Elizabeth Curzon. *North Am. Veterinarian* **20**, No. 11, 17–22(1939).—A review of the toxicity, detn., distribution, physiol. effects, etc., of nicotinic acid. 35 references. C. W. W.

Action of nuclease on cozymase. Heinz Heiwinkel. *Arkiv Kemi, Mineral. Geol.* **13A**, No. 19, 12 pp.(1939).—Nuclease from emulsin of sweet almonds was used. NaF completely inhibited the dephosphorylation of cozymase, but the latter was split into its 2 nucleotides by hydrolysis at the union of the 2 phosphate groups. J. J. Willaman

Enzymic phosphorylation and dehydrogenation in brain, nerve and sarcoma. Hans v. Euler. *Arkiv Kemi, Mineral. Geol.* **13B**, No. 11, 6 pp.(1939).—With the time of reduction of methylene blue as a measure, the dehydrogenase system of Jensen sarcoma and of rat brain was inhibited by insulin, but accelerated by muscle adenylic acid. J. J. Willaman

Dipeptidase action of extracts of Jensen sarcoma and of rat muscle. Bolesław Skarżyński. *Arkiv Kemi, Mineral. Geol.* **13B**, No. 13, 7 pp.(1939).—Exts. of rat muscle (I) and of Jensen sarcoma (II) hydrolyzed *dl*-alanylglycine with equal rate and to the extent of 50% only. I hydrolyzed glycylglycine to the extent of 25%, but II to 89%. Both split *l*-leucylalanine to about 50%, but neither acted on the *d*-form. J. J. Willaman

Water in nonaq. solns. [biol. systems] (Osterhout, Murray) **2**. Further expts. on decompn. and regeneration of nitrogenous org. matter in sea water (Brand, *et al.*) **2**. Structure of cellulose and other polymers related to simple sugars (Haworth) **10**.

B—METHODS AND APPARATUS

GLENN E. CULLEN

Application of the Pulfrich photometer to the determination of sulfates by the method of Marenzi and Banfi. A. D. Marenzi and R. F. Banfi. *Anales farm. bioquím.* (Buenos Aires) **10**, 77–81(1939); cf. *C. A.* **33**, 1357[4]. - The blue color is developed by reaction of the benzidine with phosphotungstomolybdic acid reagent as in the colorimetric method, then estd. photometrically with filter S72 (max. transmission at 7290 A.). L. E. Gilson

Determination of phenols in blood and urine with the Pulfrich photometer. A. D. Marenzi. *Anales farm. bioquím.* (Buenos Aires) **10**, 82–7(1939).—The colorimetric method of M. (cf. *C. A.* **26**, 2999) is adapted to photometric detn. Filter S47 (max. transmission at 4630 A.) is used. L. E. Gilson

Determination of prothrombin. Armand J. Quick. *Proc. Soc. Exptl. Biol. Med.* **42**, 788–9(1939); cf. *C. A.* **33**, 8226[1].—Discussion based on previous papers (*C. A.* **31**, 2660[8]; **33**, 8258[3]). L. E. Gilson

The composition of the alveolar air and its clinical determination. R. Lemaire. *Anesthésie et analgésie* **5**, 326–30(1939).—Consistent results were obtained with the Henderson and Haggard technique (cf. *C. A.* **19**, 3506) as modified by Cordier (unpublished results). The Cordier modification involves a smaller mouthpiece and valves of lower resistance. Marion Horn

Histaminase. I. Chemical method for determining the activity of histaminase. Kiyooki Takahasi and Tosio Umeda. *J. Agr. Chem. Soc. Japan* **15**, 939–46; *Bull. Agr. Chem. Soc. Japan* **15**, 137–8(1939)(in English). Histamine-HCl 1 mg., phosphate buffer soln. having pH 7.2 2 cc., H_2O 10 cc. and toluene 1 cc. were taken in a test tube. Histaminase in hog kidney ext. was adsorbed on acid clay at pH 7.2. The histaminase prepn. was added. The mixt. was kept at 38° and stirred by an air current for 24 hrs. The filtrate was dild. to 20 cc., and then 0.2 cc. of satd. Na_2CO_3 soln. and 0.5 cc. of diazobenzenesulfonic acid satd. soln. were added. The quantity of histamine remaining unchanged was estd. by colorimetry. The value was corrected by reducing the quantity of histamine adsorbed in acid clay. Y. Kihara

Photometric estimation of silicic acid in biological materials. J. Bodnár and Tibor Török. *Z. physiol. Chem.* **261**, 257–68(1939).—Dry and powder the material to be analyzed and weigh 0.05–0.25 g. into a small Pt crucible with lid. Add 0.25 g. $KNaCO_3$ and mix. Heat gently at first and then more strongly ending with 40 min. in the full flame of the Teclu burner. Stir the melt occasionally. After cooling add 1–2 drops of methyl orange and just neutralize with a soln. of HCl (80 cc. concd. HCl and 920 cc. of H_2O). Heat on the water bath for a few min. Add 0.5 cc. of the HCl soln. to the cooled digest and transfer to a 15-cc. vol. flask, washing with three 1-cc. portions of H_2O. Add 0.5 cc. of 6.5% KCN (paraffined bottle) and 1.5 cc. of acid Mg mixt. (42 g. NH_4Cl, 22 g. cryst. $MgCl_2$, 1 g. citric acid and 1.3 g. $NH_4H_2PO_4$ in 200 cc. of the HCl above). Mix and add dropwise with shaking 3 cc. of 8% NH_3 (previously distd. through paraffined tubes). Fill to the mark, transfer to a centrifuge tube and spin for 5–10 min. Transfer 10 cc. of the supernatant fluid to a 25-cc. vol. flask, add 1.5 cc. of 5% NH_4 molybdate in 5% H_2SO_4 and 1.5 cc. of 2% hydroquinone in water acidified with 2 drops H_2SO_4 per 100 cc. Mix and after 5 min. dil. to the mark with a soln. made by dissolving 30 g. Na_2SO_3 in 200 cc. of H_2O and 160 g. of Na_2CO_3 in 800 cc. of H_2O, filtering and mixing. Read the color in a photoelec. colorimeter with a red filter. Standardize the method with known amts. of SiO_2. The method requires 2 hrs. and the difference of duplicates is usually less than 5% with 5–70 γ of Si. The KCN and citric acid form sol. complexes with any Fe present and the phosphate in the Mg mixt. ensures the formation of a ppt. even with very small amts. of P in the sample. Milton Levy

A new method for the estimation of vitamin C on the Zeiss step photometer. Franz Bukatsch. *Z. physiol. Chem.* **262**, 20–8(1939).—To est. vitamin C ext. 3 g. of fresh material (leaves, roots, etc.) with 3 cc. of 20% HPO_3, grinding with sand. Add 27 cc. of air-free H_2O and filter after 10 min. To 5 or 10 cc. of filtrate acidified with glacial AcOH add 5 cc. of nitrobenzene or xylene. Add 1 cc. of a soln. of 2,6-dichlorophenolindophenol equiv. to 0.5 mg. of vitamin C and shake. If the solvent layer does not become colored add another 1 cc. of the dye soln. Excess dye is taken up by the solvent and the concn. measured at a depth of 0.5 cm. with filter S53 for nitrobenzene and S50 for xylene. 0.5 (cc. of dye − factor X extinction) gives the amt. of vitamin C in the sample. The factor is detd. on pure vitamin. If the original ext. is colored it is extd. with the solvent to be used until all extractable color is removed. Milton Levy

The Wright technique in estimating the opsonic titer of serums. Paul vor dem Esche. *Z. Immunitäts.* **96**, 242–52 (1939). The Wright technique for detg. opsonins gives reliable results only when precautions involving prepn. of bacterial suspensions, the concn. of serum and the prepn. and staining of smears are observed. Julian H. Lewis

Experiences with the gold sol of Borovskaya. Hans Schubert. *Z. Immunitäts.* **96**, 267–74(1939).—This gold sol (*C. A.* **28**, 5485[3]) when carefully made is an inexpensive easily prepd. reagent which gives uniform and trustworthy results. Julian H. Lewis

The determination of purine nucleotides and nucleosides in blood and tissues. Stanley E. Kerr and Krikor Seraidarian. *J. Biol. Chem.* **132**, 147–59(1940); cf. *C. A.* **27**, 716. - The method previously described for the detn. of purine nucleotides in CCl_3CO_2H exts. of tissues has been simplified and also extended to permit the sep. estn. of adenine and hypoxanthine by the method of Hitchings (*Dissertation*, Harvard, 1933). A. P. Lothrop

A rapid micro-Kjeldahl method. Ancel Keys. *J. Biol. Chem.* **132**, 181–7(1940).—A rapid accurate micro-Kjeldahl method is described which can be used for the detn. of amts. of N corresponding to that contained in 0.1–0.2 cc. of blood serum. The method involves measurement of samples and standard acid with syringe pipets, distn. in partial vacuum and titration with a 0.2-cc. microburet. Under ordinary conditions of work, from 6 to 8 detns., including blanks and controls, can be carried out from start to finish in 2 hrs. by a single analyst who can also run as many as 40 detns. in a day with 2 stills. A. P. Lothrop

Apparatus for the continuous drying and extraction of biological materials. Application to the extraction of the neutral fat fraction of feces. Irving A. Kaye, I. Wallace Leibner and Edwin B. Connor. *J. Biol. Chem.* **132**, 195–207(1940).—An app. is described which is capable of drying biol. materials, such as feces, tissues, organs, bones, blood and other body fluids, and extg. org. substances such as fats, drugs and poisons. Oxidation is prevented by avoiding high temps. and an atm. of O_2, the vapors of the solvent having displaced the air. The drying time is considerably cut and the extn. is more thorough than in the usual extn. by the Soxhlet procedure. A new solvent, iso-Pr_2O, for the extn. of fat from feces is recommended and has proven more efficient than other common fat solvents. A method is described for the study of *the neutral fat fraction of feces.* A. P. Lothrop

The determination of arginine by means of flavianic acid. Hubert B. Vickery. *J. Biol. Chem.* **132**, 325–42 (1940).—In the method described for the detn. of arginine, which is a fundamental modification of the flavianic acid method of Kossel and Gross (*C. A.* **18**, 2871), the arginine is pptd. from protein hydrolyzates as the diflavianate which is purified by soln. in NH_4OH and repptn. in slightly acid

soln. as the monoflavianate which is filtered off and weighed. From 3 to 5 g. of protein is required for each detn. and the results are highly reproducible and apparently reliable. The results are usually a little higher than those obtained by the Ag pptn. method. A. P. Lothrop

A method for the determination of small amounts of potassium. T. E. Weichselbaum, Michael Somogyi and Howard A. Rusk. *J. Biol. Chem.* **132**, 343–56(1940).—A micromethod is described for the detn. of K in 0.5 cc. of serum, the useful range extending from a min. value of 15 to a max. of 40 mg. of K per 100 cc. of serum, a range that covers most abnormal and exptl. conditions. In extreme instances 1 cc. or 0.25 cc. may be used. The proteins and chlorides are pptd. from the serum by use of $CuSO_4$, Na_2WO_4 and $AgNO_3$ solns. The K is then pptd. as Ag K cobaltinitrite and the ppt. analyzed by either manometric detn. of nitrite or titrimetric detn. of Ag. The authors prefer the gasometric technique for its precision but the titrimetric procedure is more rapid and easier to perform. The 2 procedures are practically interchangeable as far as accuracy of results is concerned. *The K content of* the *serum* of 40 normal subjects was found to be as follows: min. 18.0, max. 20.6, av. 19.3 mg. %. The range is quite narrow and is at variance with the wide range of values found in the literature. A. P. Lothrop

A critical study of the *p*-dimethylaminobenzaldehyde method for determining tryptophan as contrasted with the glyoxylic acid method. J. L. D. Shaw and W. D. McFarlane. *J. Biol. Chem.* **132**, 387–92(1940); cf. *C. A.* **33**, 5058.—The *p*-dimethylaminobenzaldehyde method of May and Rose (*C. A.* **17**, 116) for the estn. of tryptophan in proteins gives erroneous results because tryptophan as combined in the protein mol. gives more color with the aldehyde reagent than does an equiv. amt. of free tryptophan. The mode of linkage and degree of oxidation of tryptophan influence the color reaction so that the source of error is the use of free tryptophan as the standard. The reliability of the glyoxylic acid method was confirmed. A. P. Lothrop

Estimation of sulfapyridine (M. and B. 693). H. H. van der Zoo de Jong. *Lancet* **1939, II**, 833. A modification of the method of Marshall, *et al.* (*C. A.* **31**, 8575[5]) is described in which diazotization of sulfapyridine is carried out in an aq. acid soln. To 1 cc. CCl_3COOH filtrate from serum or other body fluid add 0.1 cc. 0.15% $NaNO_2$ soln. and, after 3 min., 3 cc. of a 0.1% soln. of dimethyl-α-naphthylamine (I) in 95% alc. After 5–10 min. compare the color with that given by appropriate dilns. of a standard soln. contg. 0.02% phenol red and 1% Na_2HPO_4. To det. total sulfapyridine, add 0.5 cc. 20% CCl_3COOH to 1 cc. filtrate from serum or 1 cc. acid to 1 cc. filtrate from nonprotein fluids and heat in boiling water for 0.5 hr. Cool, adjust the vol. to 1.5 cc., add 0.15 cc. of 0.15% $NaNO_2$ soln., and after 3 min., 4.5 cc. reagent I. E. R. Main

Titration of vitamin C. A simplified technique of standardizing solutions of ascorbic acid. Névio Pimenta. *O Hospital* **16**, 439–43(1939).—In order to det. ascorbic acid in the soln. used to standardize 2,6-dichlorophenolindophenol it is proposed to replace the little stable 0.01 *N* iodine soln., whose titer must often be checked with $Na_2S_2O_3$, by the very stable 0.01 *N* KIO_3 soln. in the known mixt. with KI and dil. H_2SO_4. George Nachod

Changes in the chemistry of cerebrospinal fluid during encephalography. A. Levinson, I. Kaplan and D. J. Cohn. *J. Lab. Clin. Med.* **25**, 225–37(1939).—The phosphatase, sugar and total protein contents of cerebrospinal fluid are increased after injection of air into the spine and ventricles; Ca and P contents are increased in some cases; chlorides, nonprotein N, lipase, tributyrinase, esterase, amylase and antitrypsin contents show no significant variation. Probable causes for these changes are discussed. Howard W. Robinson

Studies in blood preservation. Fate of cellular elements in relation to potassium diffusion. Charles R. Drew, Katharine Edsall and John Scudder. *J. Lab. Clin. Med.* **25**, 240–5(1939); cf. *C. A.* **33**, 8653[3].—Heparinized human blood was kept at approx. 4° in a refrigerator and changes in the cellular elements were followed for an exptl. period of about 30 days. Red blood cell destruction plays at most only a small part in the steady increase of the K content of the plasma because there is little or no actual loss in the count during this period when the K of the plasma reaches a level 10 times normal. The hemoglobin content remains const. in the total sample though 15 to 25% may be found in plasma. The mean cell diam. of the red cells is reduced approx. 20%. The polymorphonuclear leucocytes are diminished by 50% in 48 hrs. and are amorphous masses in 15 days. The lymphocytes, monocytes and eosinophiles do not disintegrate so rapidly, the last named are very resistant. The thrombocytes rapidly fall to a level of about 30,000 in 72 hrs. and then remain const. Howard W. Robinson

A stable adrenal cortical extract. R. J. Schachter. *J. Lab. Clin. Med.* **25**, 281–5(1939).—Adrenal cortical ext., which was found to retain its potency upon standing at room temp. for at least 18 months, was prepd. from the glands of freshly slaughtered cattle with the use of only 2 extractives, EtOH and C_6H_6. The details of the method of prepn. are given. The ext. is free from N; 5 cc. injected intravenously into ether-anesthetized cats had no effect on the blood pressure, showing that the adrenaline content is low; and 2 samples tested for choline by Eagle (*Proc. Soc. Exptl. Biol. Med.* **30**, 1094(1933)) contained 1.8 and 1.2 γ per cc. Howard W. Robinson

The determination of urea in blood and urine by Conway units. Kurt Steinitz. *J. Lab. Clin. Med.* **25**, 288–91(1939).—The advantages of the Conway method (*C. A.* **27**, 3857) are summarized and the technique is briefly described. Howard W. Robinson

A new Sahli type hemoglobinometer. Russell L. Haden. *J. Lab. Clin. Med.* **25**, 325–7(1939); cf. *C. A.* **27**, 5359.—In this app. the glass standard is divided into 3 windows, separated by opaque bands. The central window contains standard color with which the specimen (blood dild. with 0.1 *N* HCl) is to be matched, the lower contains a color that is 5% darker, the upper window one that is 5% lighter. With this set-up the sample is dild. with water until the color approximates that of the lower window and then is dild. further until the color matches the middle window. The app. has been standardized to read in g. of hemoglobin per 100 cc. by comparing readings with those made on the Haden-Hausser lab. model instrument (*J. Lab. Clin. Med.* **16**, 68(1930)). H. W. Robinson

Analysis of protein by means of deuterium-containing amino acids. Hans H. Ussing. *Nature* **144**, 977(1939); cf. *C. A.* **32**, 8538[4].—A method is described for analysis of protein by means of amino acids contg. D. It is suggested that this method can be used for the detn. of alanine, valine, isoleucine and aspartic acid. E. D. W.

Anserine in muscle: possibility of determination by titration. E. C. Bate Smith. *Nature* **144**, 1015(1939); cf. *C. A.* **32**, 5011[9].—A possible titration method is described for the detn. of anserine in muscle. The detn. can be carried out in a few hrs. as compared with the several days needed for the Zapp and Wilson method (*C. A.* **33**, 6675). E. D. Walter

Microestn. of sulfates in sea water and body fluids of marine animals (Webb) **7**. Method for detg. very small quantities of Mo applicable to biol. material (Bertrand) **7**.

C—MICROBIOLOGY

LAWRENCE H. JAMES

Action of a quaternary ammonium type of wetting agent on metabolism of microörganisms associated with dental caries. Benjamin F. Miller, Zelma Baker and R. W. Harrison. *Proc. Soc. Exptl. Biol. Med.* **42**, 705–6(1939).—A preliminary report on Zephiran (alkyldimethylbenzylammonium chloride). L. E. Gilson

Relation between the reaction of the medium and the activity growth substances. Yu. V. Rakitin and L. M. Yarkovaya. *Compt. rend. acad. sci. U. R. S. S.* **23**, 952–4(1939)(in English).—The variation of growth

reaction with the acidity of the medium and buffer solns. was studied with reference to the coleoptiles of *Avena*, with sulfuric, oxalic, citric, and malic acids as media and 6% gelatin for control. It yielded results (in tables) showing that the intensity of growth reaction grows with the concn. of H_2 ions in the medium. A given amt. of growth substance varies within a wide range of activity according to the pH of the medium. The stronger the concn. of H_2 ions, the more active the growth substances. 8 references. A. H. Krappe

Biochemical preparation of inosose. A. J. Kluyver and A. G. J. Boezaardt. *Rec. trav. chim.* **58**, 956–8(1939)(in English).—A study of the oxidation of meso-inositol (I) by *Pseudomonas beijerinekii* showed an analogy between this biol. oxidation and the oxidative action of concd. HNO_3 in the Scherer reaction and suggested that the incomplete biol. oxidation of I by *Acetobacter suboxydans* would yield a monoketoinositol, inosose (II), identical with the product obtained by Posternak (*C. A.* **31**, 1774[9]) by the action of concd. HNO_3 on I. Yeast ext. (350 cc.) contg. 3% I in a 1 l. Schott aeration flask was sterilized, inoculated with *A. suboxydans* (strain E. I. 4, 7, 1) and incubated at 30° for 24 hrs. in the presence of a slow current of air. The aeration was increased and the incubation was carried on for 10 days. The reducing power of the medium was periodically detd. No increase was noted after 6 days. The medium was evapd. at 35°, extd. with boiling H_2O, filtered and evapd. to dryness. Recrystn. from boiling H_2O gave 90% of II, m. 200° (decompn.) and identical with the product obtained by P. in 16–25% yields. C. R. Addinall

Biologic nature of the bacteriostatic effect of sulfapyridine against the pneumococcus. Ralph R. Mellon and Ruth A. McKinney. *Proc. Soc. Exptl. Biol. Med.* **42**, 677–9(1939).—Preliminary. L. E. Gilson

The content of purine bases in yeasts during their growth in different media. B. Kagan and M. Stadnichenko. *Mikrobiol. Zhur.* **5**, No. 2, 93–102(1938); *Khim. Referat. Zhur.* **2**, No. 4, 67(1939).—Yeasts are very rich in proteins (45–70%). Their high content of purine bases (2–1.3% as compared with 0.13–0.26% and 0.18% in meat and eggs, resp.) makes them unsuitable as food products. K. and S. investigated the influence of culture media on the content of the purines in different races of yeast. *Saccharomyces cerevisiae* of the *Bast* and *S* race, and *Torula utilis* (Henneberg strain) were investigated. For the prepn. of the "yeast mass" a method was used (which is employed in yeast-producing factories) which consists of 2 stages: the rejuvenation of the culture and the cultivation of the last generation by air blowing. The cultivation was performed at 28° with air blowing for 12 hrs. in 3 media: dild. must (7° Ball), dild. molasses [3° Ball + $(NH_4)_2SO_4$, $MgSO_4$, KH_2PO_4] and the mineral soln. of Mayer (sucrose 15.0%, KH_2PO_4 5.0%, $MgSO_4$ 5.0%, $CaHPO_4$ 0.5%, NH_4NO_3 0.75%, distd. water 1 l.; pH = 5.0). The total purine N was detd. according to the micro method of Schmidt. Investigations showed that the amt. of purines depends on the condition of the growth of the culture. *Torula utilis* had a min. amt. of purines in molasses; the content of purines in the *Bast* race was considerably smaller when cultivated under plant conditions than under lab. conditions (0.80% and 1.69–1.93% of the purine N). *Torula utilis* contains a small percentage of the purine N (0.9%) in spite of a large amt. of the total N (9.19%). On cultivation in must and in Mayer's media a decrease of the total N (in must 8.20%, in Mayer's medium 7.75%) and a considerable increase of the purine N (in must 1.62%, in Mayer's medium 1.88%) is observed. A parallel decrease of the amt. of purines with the decrease of the amt. of the total N is observed in the *S* race. W. R. Henn

Biochemical properties of the acetic acid bacteria of the group of quick-vinegar bacteria. A. P. Vasil'ev and I. M. Shains'ka. *Mikrobiol. Zhur.* **5**, No. 3, 63–71(1938); *Khim. Referat. Zhur.* **2**, No. 4, 65(1939).—The assimilation of N and C from different sources by the following acetic acid bacteria of the quick-vinegar bacterial group was investigated: *Bacterium schützenbachii* (9 strains), *B. orleanese* (16 strains) and *B. curvum* (4 strains). The bacteria were taken from the Kiev vinegar works and raised on synthetic media of Simons-Drobot'ko (sources of C 1.0 g., N 1.0 g., K_2HPO_4 1.0 g., $MgSO_4$ 0.2 g., NaCl 5.0 g., distd. water 1.0 l., and washed agar agar 20.0 g.) in which the sources of C and N were varied. The degree of assimilation was detd. by the intensity of the growth of the bacteria. The sources of N (with glucose as the source of C) can be given in the following order according to their degree of assimilation of N: asparagine, NH_4NO_3, urea and KNO_3 (for *B. schützenbachii* only KNO_3 is a better source of N than NH_4). Urea is clearly unsuitable as a source of N. The following substances were investigated as sources of C: Na citrate, Na lactate, Na succinate, Na acetate, EtOH and glycerol. The sources of N were the same substances as in the previous expt. Best results were obtained with Na lactate and Na succinate, and worst results with Na acetate, EtOH and glycerol. The relation between the sources of N and C can be given as follows. The *B. curvum* medium with Na acetate and urea was not assimilated by any of the strains while the media with Na acetate and NH_4 N were assimilated by all strains. The results obtained show that the strains of the same kind can differ greatly according to their biochem. properties, and that the strains of different kinds can be similar according to their physiol. properties. These facts create doubts as to the existence of the types *B. schützenbachii*, *B. orleanese* and *B. curvum* as sep. classified substances. W. R. Henn

The effect of pH on growth and gas production by streptococci and lactobacilli. J. G. Davis and C. C. Thiel. *J. Dairy Research* **10**, 455–63(1939).—The pH range of growth of streptococci and lactobacilli in dextrose yeast casein digest broth was studied. Nearly all the group I and II streptococci grew at pH 8.8, but only the enterococci grew at pH 4.8; all group III types (heterofermentative) grew at pH 4.4. Only a few lactobacilli grew at pH 8.8 but most were able to grow at pH 4 if other conditions were favorable. The enterococci, *Str. lactis* and *Str. cremoris*, could be differentiated by the alk. limits of growth. A. H. Johnson

Production of growth substance on peptone broth by crown-gall bacteria and related nongall-forming organisms. S. B. Locke, A. J. Riker and B. M. Duggar. *J. Agr. Research* **59**, 519–25(1939).—Single-cell bacterial cultures of 3 organisms (virulent crown gall, attenuated crown gall and *Bacillus radiobacter*) differing widely in ability to induce overgrowths in plants, but similar in physiology, were found to be similar in their capacity to produce growth substance in peptone broth. Thus far evidence seems lacking for the view that β-indoleacetic acid or any other known growth substance produced in such cultures has a direct major relation to the pathogenicity of crown-gall bacteria. W. H. Ross

The nature of growth substance originating in crown gall tissue. S. B. Locke, A. J. Riker and B. M. Duggar. *J. Agr. Research* **59**, 535–9(1939); cf. preceding abstr.—Growth substances obtained by ether extn. from tomato crown gall tissue, tomato foliage and crown gall culture on peptone broth all appeared to contain either β-indoleacetic acid or material similar in its sensitivity to acid and alkali. Identification was based on the stability of a crude ext. in hot acid and basic solns. No evidence was obtained of the presence of auxin a or b in these exts. The growth substance measured might have come either from the plant or from the bacteria. W. H. Ross

Infrared absorption spectra of various strains of purple bacteria. E. C. Wassink, E. Katz and R. Dorrestein. *Enzymologia* **7**, 113–29(1939)(in English).—Different strains of purple bacteria have different infrared absorption spectra, as a rule with 2 max. The alc. ext. of bacteriochlorophyll in all cases shows the same absorption spectrum with 1 chief max. Tables are given of the values of the max. Most spectra were analyzable into 3 sym. absorption bands with a half-value width of the order of 0.05 eV. Position and relative magnitude of these bands differ in the various strains. The corresponding bands of most strains investigated lie close together.

With the purple S bacterium strain D, it was observed that the relative magnitude, especially of the 2 chief max. is not const. This variation is not due to fixed genetic variation within the strain. It could be influenced by some environmental conditions, e. g., the light intensity applied during the growth of the cultures. In the purple bacterium the same bacteriochlorophyll is in the intact cell, bound to different proteins, thus building up different photoactive complexes characterized by somewhat different infrared absorption. Felix Saunders

Nonactivation of pyruvic acid oxidation by free vitamin B_1 (thiamine). Fritz Lipmann. *Enzymologia* **7**, 142–5 (1939)(in German); cf. *C. A.* **32**, 9204[4]. — In contrast to the decarboxylation in yeast, the oxidation of pyruvic acid in *Bact. delbrückii* is not stimulated by the addn. of free thiamine to a system partially satd. with cocarboxylase. Felix Saunders

Determination of the products from C_2 and C_4 particles in the citric acid dissimilation of sugars by Aspergillus. V. Bolcato and P. Tono. *Enzymologia* **7**, 146–56(1939) (in Italian). C_2 and C_4 particles such as AcH, glycolaldehyde, glycolic acid, glyoxylic acid, fumaric acid, malic acid and oxalacetic acid were isolated and identified from the fermentation products of *A. niger* acting on a sucrose soln. in the presence of Na_2SO_3. The authors believe that the formation of citric acid is preceded by a breakdown of the sugar mol. into C_2 and C_4 particles. Felix Saunders

Flash of luminescence following anaerobiosis of luminous bacteria. Frank H. Johnson, K. L. van Schouwenburg and A. van der Burg. *Enzymologia* **7**, 195–224 (1939)(in English); cf. *C. A.* **33**, 791[2].—When O is added to a suspension of luminous bacteria, previously dark or dim because of O lack, a max. flash occurs after very short times of anaerobiosis. With long periods of anaerobiosis in the absence of added substrate, the flash is very small and is followed by a secondary rise in luminescence intensity during the course of some 2 min. The max. intensity during this interval exceeds both the flash and the normal level prior to the anaerobiosis. It gradually falls to the same intensity as this previous normal level. With suspensions contg. glucose, the same relations hold for short periods of anaerobiosis, although the abs. luminescities are greater. Long periods of anaerobiosis in the presence of glucose cause no change in either the flash or final level and no secondary rise appears. In the case of very long periods of anaerobiosis (more than 2 hrs.) both the flash and the final level are irreversibly reduced in proportion. Suspensions contg. substrates that cannot be metabolized in the absence of O show the same behavior as suspensions without added substrate. When glucose is added anaerobically to cells that have been aerated for a long time in the absence of substrate, the flash and final level become increasingly greater with the time of anaerobiosis. The intensity immediately following the flash is nearly the same as that of an aerated control suspension. The increase in flash occurs with compds. that can be metabolized in the absence of O (glucose, peptone, pyruvate). Other substances whose breakdown depends on the presence of O (glycerol, succinate) have no effect on the flash under these conditions, but an increase in luminescence occurs with subsequent aeration. In the case of fumarate the results are intermediate between these 2 general types of effect. Lactate, boiled bacteria and distd. water-cytolyzed bacteria have no effect. An interpretation is given in terms of reactions previously discussed. When added simultaneously with O, urethan readily decreases the intensity of the flash as well as that which immediately follows. In the case of strong concns. (1 *M*) the flash is nearly abolished, and luminescence is irreversibly extinguished. In concns. up to 0.01 *M*, cyanide has no effect on the flash when added simultaneously with O. Urethan acts directly on luciferase in the light-emitting oxidation, while cyanide does not act directly on any of the reactions immediately concerned in bacterial luminescence. Felix Saunders

Fixation of acetaldehyde in alcoholic fermentation. Carl Neuberg and Rudolf Ziffer. *Enzymologia* **7**, 225–7 (1939)(in German).—2,4-Dinitrophenylhydrazine can be used to fix AcH formed during alc. fermentation by yeast. Felix Saunders

Comparison of the cellulose decomposition by culture strains of the rice blast fungus, Piricularia oryzae Br. et Cav. Y. Inoue. *Ann. Phytopath. Soc. Japan* **9**, 33–40 (1939); *Rev. Applied Mycol.* **18**, 708.—Of 21 strains of *Piricularia oryzae*, the agent of rice blast in Japan, compared on a synthetic agar medium contg. cellulose for their cellulose-decompg. properties 9 were very active, 3 very weak and the remainder intermediate. In general the higher the degree of pathogenicity to rice the stronger the capacity for cellulose disintegration. O. E. S.

The pigment of Bacillus violaceus. IV. The nature of the violacein molecule and factors influencing its stability. Walter C. Tobie. *Bull. assoc. diplômés microbiol. faculté pharm. Nancy* No. **18**, 7–19(1939)(in English); cf. Sartory, Meyer and Waeldele, *C. A.* **32**, 5438[1], 9168[2].—Mainly a critical review on the chemistry of the violet pigment violacein (I), the precautions to be observed in its prepn. and purification, and its presumed physiol. function (cf. Friedheim, *C. A.* **26**, 4623). Exptl. evidence regarding the production of pyrrolic substances of high mol. wt. by the strong reduction of I (cf. *C. A.* **31**, 7071[6]) is given in detail. The pigment sublimes in a high vacuum and might be purified by this means. As reported by different workers, the properties of I vary considerably. It is possible that I represents a class of compds. rather than being an individual compd. A qual. test for I is the green soln. which it gives with pyruvic acid. The green color may be due to a dehydrogenation of I, the acid acting as H acceptor. A provisional structural formula for part of the I molecule is given, based upon the molecular formula of Wrede and Swane (*C. A.* **32**, 9162[2]) and upon the apparent relationship of I to indigo (*C. A.* **32**, 2563[3]). The pigment of Clemo and McIlwain (II) from a bacillus designated as *Chromobacterium iodinum* (*C. A.* **32**, 5402[6]) is not I but is apparently 1,2-dihydroxyphenazine 9,10-dioxide. To avoid confusion with I, the name *clemoine* is suggested for II and the name *Pseudomonas clemo* for the microörganism. 25 references. W. C. Tobie

The use of Brilliant Green, sodium azide and dextrose in the microscopic and Hotis tests for streptococcic mastitis. C. S. Bryan, E. D. Devereux, W. C. Hirschey and A. C. Corbett. *North Am. Veterinarian* **20**, No. 9, 41–6(1939).—Expts. were carried out to det. the effectiveness of Brilliant Green and Na azide in suppressing bacteria other than streptococci and to det. the value of dextrose and phys. factors in obtaining max. growth of streptococci during the time interval of the microscopic and Hotis tests. (Hotis and Miller, *U. S. Dept. Agr. Circ.* No. 400(1936).) From tests on the milk of several hundred cows it was concluded that better results were obtained from a selective preservative contg. Brilliant Green, Na azide and dextrose than from either preservative used alone and the use of a selective preservative yielding a final diln. of 1:50,000 of Brilliant Green, 1:15,000 of Na azide and 1:1000 of dextrose in the milk is recommended. This preservative increased the accuracy of the microscopic test as compared to the use of Brilliant Green alone and greatly reduced the time required to read the results by suppressing both the udder micrococci and contaminating bacteria. The use of this preservative in the Hotis test increased the 24-hr. reading from 60 to 81% efficiency and reduced the no. of negative cows giving positive tests from 7.3 to 2.6%. Similar improvement was obtained in the 48-hr. reading. The addn. of dextrose compensated for the low lactose content of the milk of mastitis-infected cows and permitted better growth of the streptococci in the sample. Colin W. Whittaker

Fermentation degumming of waste silk—useful thermophilic bacteria for fermentation degumming (Katagiri, Nakahama) **25**. Importance of biol. research for drinking water (Batta, *et al.*) **14**. Light absorption by derivs. of the bacteriochlorophylls (Stern, Pruckner) **3**.

The response of tobacco seedlings to the growth-promoting substance "heteroauxin." E. T. McEvoy. *The Lighter* **9**, No. 4, 14–16(1939).—The use of small concns. of heteroauxin produced no observable results on the growth of tobacco seedlings. Higher concns. accelerated the rate of growth of both tops and roots. If too high a concn. of heteroauxin was used the growth was inhibited. J. R. Adams

Surface sterilization of nodules with calcium hypochlorite. J. K. Wilson and T. Punyasingha. *J. Am. Soc. Agron.* **31**, 1016–19(1939).—The undesirable organisms on the surface of the nodules of leguminous plants can be removed by immersing the nodules in a soln. of $CaOCl_2$ for the desired length of time. The soln. is prepd. by triturating 10 g. of com. chlorinated lime with 350 cc. of water and filtering. The time of immersion is dependent on the type and size of the nodule. This treatment leaves the cells in the center of the nodules full of viable bacteria from which pure cultures of *Rhizobium* can be obtained. J. R. Adams

Chemical and botanical study of Ilex paraguayensis St. Hilary, variety euneura Loes. Paulo Lisbôa e Costa and Jose Badini. *Tribuna farm.* (Brazil) **7**, 89 100, 111–16, 133–40, 155–61, 177–84(1939).—A botanical description of *Ilex paraguayensis* (maté herb) is given as well as the geographic distribution. The maté leaves contain H_2O 66.4, mineral ash 2.3, org. substances 31.3, caffeine 0.4, tannin 9.34, protein 11.99, cellulose and lignin 9.4 and reducing substances 0.5%. E. S. G. Barron

A trenching experiment in a spruce forest and its bearing on problems of mycotrophy. Lars-Gunnar Romell. *Svensk Botan. Tid.* **32**, 89–99(1938)(in English).—The results of trenching in an old spruce forest appear to support strongly the microbiol. theory of "mor activation" (*C. A.* **29**, 5566[9]). A fundamental physiol. difference exists between litter-decompg. fungi and tree mycorrhiza fungi. The obligate tree mycorrhiza fungi seem to be practically unable to break down dead org. residues under conditions prevailing in nature and must derive their energy food from living and functioning roots of trees while prospecting the soil for available N and mineral nutrients. The facultative mycorrhiza formers with orchids (identified species, e. g., *Armillaria mellea* and a *Marasmius*), like ordinary litter-decompg. fungi, can be cultivated on wood, leaf litter, etc. Ruth Berggren

The osmotic pressure and osmotic resistance of some marine algae. Harald Kylin. *Svensk Botan. Tid.* **32**, 238–48(1938)(in German).—The osmotic pressure (o. p.) of marine algae was estd. in solns. of sea water (salt concn. = 3.3%; o. p. = 23 atm. at 20°) contg. varying amts. of sucrose. In 8 species of Chlorophyceae the o. p. varied from 36 atm. for the tips of *Chaetomorpha aerea* to 55 atm. for *Enteromorpha intestinalis* and *Cladophora rupestris*. In 10 species of Phaeophyceae the o. p. varied from 36 atm. for the large inner cells of *Asperococcus bullosus* (I) to 55 atm. for the small outer cells of young plants of *Laminaria saccharina* (II). The younger cells of *Pylaiella litoralis* (III), *Ectocarpus siliculosus* and *Elachista fucicola* have a somewhat higher o. p. than the older cells, while the smaller outer cells of I, II and *Laminaria cloustonii* have a higher o. p. than the larger inner cells. In 21 species of Rhodophyceae the o. p. varied from 31 atm. for *Griffithsia corallina* to 50 atm. for *Polysiphonia urceolata*, the pericentral cells of *P. nigrescens* (IV) and the main branches of *Antithamnion plumula* (V). In the cells of the short leaves of V and of the hair leaves of IV the o. p. is only 41 atm. On an av. the o. p. is lower in the red algae than in the green or brown. Pieces of thallus of 28 species of fresh marine algae showed differences of behavior when placed in sea water dild. with varying amts. of distd. water; e. g., pieces of *Bonnemaisonia asparagoides* were alive in 0.7% sea water and dead in 0.4%, while pieces of *Rhizoclonium riparium* and III were alive in 0.2% sea water and dead in 0.0%. Ruth Berggren

The requirement of growth substances by various species of Marasmius. Gösta Lindeberg. *Svensk Botan. Tid.* **33**, 85-90(1939)(in German).—Ten species of *Marasmius*, including *M. foetidus*, failed to grow in synthetic media of nutrient salts and glucose unless aneurin (Merck) was also present. *M. androsaceus* did not grow in the control synthetic media, even upon the addn. of aneurin, but did grow if both aneurin and biotin (biotin Me ester) were added. The addn. of biotin alone produced a definite though slight growth. *meso*-Inositol had no effect. The rate of growth of *M. androsaceus* increased with increase in the concn. of biotin, reaching a max. when the nutrient medium (aneurin concn. = 50 γ/l.) contained 50 mγ, or possibly less, biotin per 20 cc.; a further increase in the concn. of biotin had no effect. Of 2 strains of *M. perforans* studied, strain I (5–9 months old) assimilated a synthetic nutrient medium only after the addn. of aneurin, while strain II (1 year old) required both aneurin and biotin. Species of *Marasmius* can be divided into 2 groups, those which require the presence of aneurin in the synthetic nutrient soln. for growth, and those which require both aneurin and biotin. Most of the species studied belong to the former group. Ruth Berggren

Change of hydrophilic properties of root and leaves of sugar beet. E. F. Simonova. *Colloid J.* (U. S. S. R.) **5**, 749–54(1939). The sap of sugar beet grown without sprinkling contains more "bound water" per cc. than that of well-watered beets. The amt. of "bound water" was detd. by comparing the refractive indexes of original and dild. sap; it strongly depends on the degree of dilu. J. J. Bikerman

Behavior of topped beets remaining in the ground. F. Schneider. *Centr. Zuckerind.* **47**, 943–8(1939).—Beet-testing methods are described. 11 references. W. W. Binkley

Advances in botany. F. E. Denny. *News Ed.* (*Am. Chem. Soc.*) **18**, 59–63(1940).—A review with bibliography of 46 references. E. J. C.

Polyploidy and tobacco. A. Bartolucci. *Boll. tec. ist. sper. colt. tobacchi "Leonardo Angeloni" Scafati* **36**, 141-8(1939).—Of the natural and artificial causes which induce polyploidy in plants, B. used the 2 methods of centrifuging germinating seeds and treating seeds with colchicine. A microscopic technique was developed to observe the differences in size and shape of pollen grains from sterile and fertile plants. Fertile allotetraploids were induced by both methods in the crosses of several varieties of tobacco. N. T. Farinacci

Nature of tobacco mosaic virus. Ernesto Bertarelli. *Boll. tec. ist. sper. colt. tobacchi "Leonardo Angeloni" Scafati* **36**, 154–7(1939); cf. *Il Tabacco* **509**, 9–11(1939). —A discussion with 19 references. N. T. Farinacci

Grafting of citrus plants. V. Belyaeva. *Sovet. Subtropiki* **1938**, No. 11, 52–7; *Khim. Referat. Zhur.* **2**, No. 4, 63(1939).—The max. amt. of sol. substances in fruits was produced by grafting to *Pancirus frifoliata* (from 9.8% to 12.62%) and the min. amt. by grafting to *Citrus limonia* (from 8.7% to 10.9%). The same law holds for citric acid. W. R. Henn

Substances taking part in the growth of plants. V. Pevzner. *Uspekhi Sovremennoĭ Biol.* **8**, No. 3, 529–32 (1938); *Khim. Referat. Zhur.* **2**, No. 4, 69(1939).—Data are given on the single hormones, their chem. compn., their activities, their role in the organism of the lowest and the highest types of plants, and their connections with

each other and with the substances of other physiol. activities (enzymes, vitamins). W. R. Henn

(Plant) hormones and their significance during the growth of seeds. V. I. Tovarnitskiĭ. *Uspekhi Sovremennoĭ Biol.* 9, No. 1/4, 81–97 (1938); *Khim. Referat. Zhur.* 2, No. 4, 69(1939).—A review. W. R. Henn

Biochemical studies on "bakanae" fungus of the rice. III. Physiological action of gibberellin on the plants. Teiziro Yabuta and Takesi Hayasi. *J. Agr. Chem. Soc. Japan* 15, 403–13, *Bull. Agr. Chem. Soc. Japan* 15, 82–3 (1939)(in English); cf. *C. A.* 33, 8238⁸.—Barley, buckwheat, *Phaseolus radiatus* var. *typicus* Prain., rape seed, *Luffa cylindrica* Roem, tomato, cucumber, cucurbit and morning glory were cultivated in water culture soln. contg. 0.14–3.5 mg. of gibberellin in 100 cc. The plants showed abnormal elongation similar to the case of rice seedlings. It was also observed after injection and lanolin application. Gibberellin gave no stimulating action for flowering. Y. Kihara

Utilization of Panicum frumentaceum. II. The seeds. Tetuziro Ohara. *J. Agr. Chem. Soc. Japan* 15, 507–13 (1939); cf. *C. A.* 31, 3103². The length and width of the seeds were, resp., 1.73–1.93 mm. and 1.73–1.95 mm. The wt. of the seeds was 745.9 774.2 g. per l. The percentages of the bran, the hull and the seed were, resp., 5.2 8.0, 21.9 23.6 and 70.1 71.7%. **III. Chemical compositions of the seeds and the relations among the factors.** *Ibid.* 580–601.—The analysis of the air-dried powder of the seeds gave H_2O 13.71, crude protein 15.28, pure protein 14.65, crude fat 5.36, crude fiber 1.00, ash 2.25 and sol. non-N compds. 62.41%. There were no remarkable differences in chem. compn. between the varieties or the degrees of maturity. The correlations between protein and non-N compds., crude fat and ash, and ash and non-N compds. were neg., while those between crude protein and ash, and crude protein and pure protein were pos. **IV. Chemical properties of various parts of the unhulled seeds.** *Ibid.* 602–8.—The analyses of the bran, the hull and the seed were, resp.: H_2O 13.75, 11.63 and 14.29%; crude protein 7.20, 3.69 and 15.06%; crude fat 2.72, 1.68 and 5.70%; crude fiber 23.06, 33.07 and 1.16%; crude ash 10.49, 9.60 and 1.96%; sol. non-N compds. 42.78, 40.33 and 61.83%; SiO_2 7.46, 8.39 and 0.12%; CaO 1.22, 0.15 and 0.06%; SO_3 0.27, 0.09, and 0.01%; P_2O_5 0.55, 0.35 and 0.95%; phytin P 0.21, 0.12 and 0.27%; lipoid P 0.002, 0.001 and 0.016%; inorg. P 0.008, 0.015 and 0.029%; MgO 0.23, 0.19 and 0.20%; K_2O 0.35, 0.30 and 0.43%; Na_2O 0.09, 0.09 and 0.09%; Fe_2O_3 0.03, 0.02 and 0.02%. The seeds contained 56.41% starch, 0.17% dextrin and 0.21% total sugars. The protein of the seed mainly consisted of prolamin, while the bran contained a large amt. of glutelin and albumin. The seed proteins were rich in lysine, cystine and histidine; those of the bran and the hull, in arginine. Y. Kihara

Experiments on the utility of β-indoleacetic acid as a material promoting the formation of callus in grafts of grape. Wolfgang R. Muller-Stoll. *Angew. Botan.* 20, 218–38(1938).—Expts. described are on the effect of synthetic heteroauxin in aq. soln. on the "taking" of grafts of grape. Four different concns. contg. 0.1, 0.067, 0.05 and 0.025% of the active substance were tried in regard to the effect on the formation of callus (4 different methods of application were used): (1) immersion of stock and scion into the soil immediately before grafting, treatment of the grafts through (2) immersion, (3) painting and (4) spraying. In most tests the results were most satisfactory when a soln. contg. 0.05% β-indoleacetic acid was used. Addnl. expts. involving the application of a lanolin paste contg. heteroauxin (cf. *C. A.* 28, 3443¹; 30, 131²) gave unsatisfactory results. Karla Longrée

Intake of iron through the roots, and the application of iron. Increase in yield through application of ferrous sulfate in comparison with manganous sulfate. Oscar Loew. *Angew. Botan.* 20, 238–40(1938).—The question as to how iron is taken up by plants is difficult to answer because of the well-known fact that ferric salts cannot be taken up by roots through osmosis. L. offers the following hypothesis: dead root hairs whose cytoplasm with their tonoplasts has lost its character as an osmotic membrane take on the properties of a filter, thus allowing materials such as acid salts (especially of citric acid) and glucose to pass out and into the soil. These acid salts may dissolve ferric oxide or ferric hydroxide, while the glucose may reduce the ferric salts to ferrous salts which are able to pass through the membrane of an osmotic cell. Ferrous sulfate and manganous sulfate were compared as to their effect on plant (*Cryptomeria*) growth. L. assumes that the more favorable effect of the latter material might be due to its direct effect on increasing the formation of protein in the nucleus of the plant cell, while iron is believed to act indirectly. Karla Longrée

The separation of mixed viruses on the basis of the differential reaction of their components to acidity. G. A. Kausche. *Angew. Botan.* 20, 246–56(1938).—Employing a previously described method (cf. *C. A.* 32, 6689⁹) K. sepd. a mixt. of 2 different viruses from potato, var. "Sharpe's Express." The 2 components of the mixt. proved to be tobacco mosaic virus, which became inactivated after 4 days at pH values between 7.8 and 10.8, and virus Cs_{35}. Karla Longrée

The growth-substance theory in applied botany. Hans Söding. *Angew. Botan.* 20, 407–11(1938).—A discussion. Karla Longrée

Composition of the various parts of the oat plant at successive stages of growth with special reference to the formation of lignin. Max Phillips, M. J. Goss, B. L. Davis and H. Stevens. *J. Agr. Research* 59, 319–66(1939).—The compn. of the culms, sheaths and leaves, chaff, rachises and branches of the panicle, and roots of the oat plant at successive stages of growth was studied with the object of detg. the nature and percentage of the more important constituents, and thereby learning more about the formation of lignin by the growing plant and the possible mechanism involved in the process of lignification. The results obtained indicate that the plant does not synthesize lignin from cellulose, pectin or pentosans. The data are also not in harmony with Klason's hypothesis that coniferyl alc. is the intermediate substance utilized by the plant in the synthesis of lignin. It is suggested that lignin is synthesized by the plant directly from either glucose or sucrose. Among the first steps in the synthesis of lignin is the production of a substance or substances having firmly bound methoxyl groups which may be formed in the course of splitting up carbohydrates by a process of hydrolysis, oxidation, reduction and dehydration. The observed presence of large quantities of substances, presumably carbohydrates, contg. firmly bound methoxyl groups and the gradual decrease of these substances with the increase in the content of lignin lend support to this hypothesis. 50 references. W. H. Ross

Influence of boron on flower-bud development in cotton. K. T. Holley and T. G. Dulin. *J. Agr. Research* 59, 541–5 (1939).—Water-culture studies of the B requirements of cotton showed that this element is necessary for flower-bud development in this plant, and that flowering may be seriously limited by a supply of B that is sufficient for fair vegetative growth. The results gave no evidence that B has any relation to flower-bud initiation in cotton. W. H. Ross

Phototropism. J. Van Overbeek. *Botan. Rev.* 5, 655–81(1939).—Phototropism is discussed from the chem. point of view. Felix Saunders

Chemical composition of Suckleya suckleyana. C. G. Barr, H. W. Reuszer and Frank Thorp, Jr. *Science* 90, 497–8(1939).—Studies of the carbohydrate and N content of poison *Suckleya* show the sol. carbohydrates to be chiefly reducing sugars which vary from 1% in seedlings to 2.5% in 3-months-old plants. The sucrose content shows only moderate variation. The HCN varies from a min. of 0.018% at the time of min. sugar content to a max. of 0.240% when the sugar is highest. Young plants contain a higher percentage of protein or colloidal N than old plants, but the older plants were higher in sol. N. There is

no accumulation of starch during the period of protein N diminution but there is a rapid increase in reducing sugars. The presence of available carbohydrates may stimulate the synthesis of HCN-contg. glucoside. F. Saunders

Some comments on a reforestation discovery. N. Sylvén and Helge Johnsson. *Svensk Papperstidn.* **42**, 509–12(1939).—A chronological résumé of investigations of the crossing of poplar and other trees from 1721 to date. The use of Bordeaux soln., of Cu and Hg compds. and of wax and paraffin is mentioned. These references cause S. and J. to question the validity of the Swed. pat. 95,971 on "the process of reforestation, especially of the hybrids of poplar." Wilhelm Segerblom

The mechanism of action of potassium salts in resistance to the development of bacterial diseases of plants. O. Verona. *Nuovo g. bot. ital.* **45**, 174–8(1938); *Rev. Applied Mycol.* **18**, 729–30.—Tests using *Ricinus communis* plants inoculated 13 days after sowing with *Bacterium tumefaciens* showed the effects of adding salts of Ca, K, Na, Mg and NH_4, alone or in various combinations, or powd. S on the growth and size of the tumors produced. The results showed that nitrates favored the growth of tumors, chlorides and sulfates impeded it, S was unfavorable to tumor development and that cations had no particular effect. The beneficial effect of K salts in keeping down tumor size is apparently due to the anion and not the K. Oden E. Sheppard

Effects of plant and animal hormones on seeds damaged by formaldehyde. N. H. Grace. *Can. J. Research* **17, C**, 445–51(1939); cf. *C. A.* **33**, 8697[7].—Marquis wheat was immersed in solns. of formaldehyde and formaldehyde contg. either naphthylacetic acid or estriol in concns. of 0.1, 1, 5 and 10 p. p. m., and germinated on blotting paper or grown in soil at temp. of 70–75°F. A measure of physiol. activity was shown by both chemicals from the results of germination on blotting paper; the activity of the 2 chemicals was of the same order. Growth in soil failed to show anything but injurious effects from formaldehyde. In another expt., Marquis wheat was sprinkled with solns. of formaldehyde and indolylacetic acid and grown in soil at a temp. of 50–55°F. The sprinkling treatment, which supplied one part of indolylacetic acid to a million parts of wheat by wt., reduced formaldehyde injury in a statistically significant manner. Lower concns. of the chemical did not reduce injury to a significant extent. J. W. S.

Changes in gossypol during ripening and storage of cottonseed. M. Podol'skaya. *Masloboino Zhirovoe Delo* **15**, No. 3, 9–10(1939).—To ascertain whether gossypol is present in cottonseed as a primary product or as a deriv. formed from other colored compds. changes occurring in the seed were studied. Color changes from pale yellow through orange to red were observed by spectroscopic examn. The rapidity of the change varies in different kinds of seed, being faster in Egyptian than in American cottonseed. As a rule the gossypol in seed which has been stored a few months is in the red form. The yellow and orange-yellow forms are nearly or quite identical with the red and lemon-yellow forms in qual. reactions, soly. in various solvents and elementary compn. J. F. S.

The agglutination of Phytomonas tumefaciens by certain plant juices. J. Magrou. *Bull. assoc. diplômés microbiol. faculté pharm. Nancy* No. **18**, 20–3(1939); cf. *Ann. inst. Pasteur* **60**, 565(1938).—Plants inoculated 3–4 months previously with *Phytomonas tumefaciens* showed agglutinins. The upper limits of diln. of the plant juices at which agglutination occurred were $^1/_{1000}$ for *Pelargonium zonale* and $^1/_{10,000}$ for *Chrysanthemum frutescens*. There was no cross-agglutination for *Phytomonas malvacearum*, *P. flaccumfaciens*, *P. mori* or *Erwinia carotovora*. The agglutinin is destroyed at 100°. The divergent results of Lasseur and Renaux (*C. A.* **30**, 7149[9]) are discussed. Cf. *C. A.* **33**, 8679[7]. W. C. Tobie

Utilization of carbohydrates in leguminous symbiosis. G. Bond. *Nature* **144**, 906–7(1939).—The evolution of CO_2 from the root systems of nodulated and of nodule-free, nitrate-fed soybean plants growing in water culture was compared. The amt. of CO_2 produced by the nodules was slightly greater than that from the roots alone. If the respiration of nodules is partly anaerobic, then it is possible that in these water-culture plants the amt. of carbohydrate utilized in nodule respiration exceeded that used by the roots themselves. E. D. Walter

Two interesting summer grasses: Penniisetum clandestinum and Chloris gayana. Teófilo Henry. *Rev. mens. asoc. rural Uruguay* **66**, No. 8, 77–84(1939).—Samples of each of these grasses from several localities were analyzed for protein, ether ext. and cellulose. C. W. Whittaker

Respiration of certain woody plants in West Norway winter. Gunnar Ålvik. *Medd. Vestlandets forst. Forsøksstа.* **6**, 7–266(1939).—A comprehensive study of the respiration of 9 species of evergreen trees and shrubs, both broadleaf and needles, in relation to temp. and light intensity. Bibliography and 125 tables of data. J. J. W.

Composition of the alcoholic extract of cane leaves and its relation to the development of the cane. C. E. Beauchamp and F. Lazo. *Proc. 12th Ann. Conf., Asoc. tecnicos azucar., Cuba* 1938, 40–55. Previous work (*C. A.* **33**, 6911[4]) was continued. Sugar cane was differentially fertilized with N, P and K. Crude chlorophyll was extd. from the leaves of the young cane (3½ months) and analyzed for N, P, K, Ca and Mg. At harvest, 23 months after planting, the yield and sugar percentage of the cane were correlated with the compn. of the crude chlorophyll at 3½ months. Diam. and wt. of stalks, no. of stalks per stool, total cane wt. and amt. of recoverable sugar in the cane juice at harvest were in definite proportion to the amt. of K in the crude chlorophyll of the young cane, which in turn was in definite proportion to the amt. of K in the fertilizer. Other relations: increments of P in the fertilizer did not increase the P content of the crude chlorophyll nor the yield of cane, except when the larger addns. of P in the fertilizer were accompanied by a larger addn. of K; where the fertilizer was low in K a large increment of P therein increased the sugar content of the juice, but with fertilizers rich in K the sugar content was high irrespective of the amt. of P in the chlorophyll; an increase of N in the fertilizer reduced the content of K, P, Ca and Mg in the crude chlorophyll, and the sugar content of the juice, but this latter effect was to some extent counteracted by an increase of K fertilizer; increase of P in the fertilizer reduced the content of Ca in the chlorophyll but increased the Mg content, while increase of K fertilizer had the reverse effect. On the other hand, increments of K increased the Ca in the chlorophyll but reduced the Mg content. The work indicates that the compn. of the crude chlorophyll of the young plants is a forecast of the results at harvest. O. W. Willcox

PHILIP B. HAWK

Purity and activity of vitamin A preparations. P. Karrer. *Helv. Chim. Acta* **22**, 1149–50(1939).—Recently a particularly pure prepn. of vitamin A was reported (*C. A.* **33**, 8250[7]) with $E_{1\,cm}^{1\%}$ 328 mμ = 1800 (EtOH); Carr-Price unit, 92,000–94,000; biol. activity 2.32 international units, whereas axerophthol (*C. A.* **28**, 2040[8]) gave $E_{1\,cm.}^{1\%}$ 328 mμ = 1700; Carr-Price unit, 100,000; biol. activity 2.5 international units. Comparison of this latter prepn. with cryst. vitamin A (*C. A.* **31**, 8634[6]) showed no essential difference. It is an error to suppose that a prepn. obtained by crystn. is necessarily more pure than one produced by chromatographic analysis. The *p*-nitrobenzoate (*C. A.* **27**, 4808) and stearate of vitamin A (Kurt Schöpp, *Diss.* Zürich, p. 51(1934) were prepd. previously. C. R. Addinall

Pathological and physical studies on the blood of infants

with nutritional disturbances, especially toxicoses. Syoiti Akiba. *Oriental J. Diseases Infants* **24**, 13–16(1938)(in German).—A study of the migration velocity of the leucocytes in healthy infants and in those with various nutritional disturbances. *Ibid.* 17–20.—A continuation of the study of the migration velocity of the leucocytes and of the blood picture in normal infants and those with nutritional disturbances. *Ibid.* 21–3.—In those cases of nutritional disturbances, in which the blood has a relatively high viscosity, the migration velocity of the neutrophile leucocytes falls more markedly than in those with a lower viscosity of the blood. In general, severe cases were accompanied by a marked lowering of the leucocyte velocity and increase in blood viscosity. The injection of moderately large quantities of hypotonic dextrose, Locke, Ringer or saline solns., rather than blood transfusions, are recommended in the treatment of nutritional disturbances. Ruth Berggren

Vitamin C studies on surgical patients. Marshall K. Bartlett, Chester M. Jones and Anna E. Ryan. *Ann. Surg.* **111**, 1–26(1940).—After operation, the fasting level of vitamin C in the blood plasma shows a consistent drop with gradual return to the preoperative value. There is no increase in the vitamin C excreted in the urine after operation even after the intravenous administration of 1 g. of cevitamic acid. After operation the clearance curves for vitamin C may show a marked change in contour. These changes are influenced by the general nutritional state of the patient, by the degree of vitamin C depletion and by the extent of the surgical procedure. The more rapid clearance from the fasting blood of vitamin C administered intravenously after operation is possibly dependent upon an increased need for this substance in the process of tissue repair and wound healing. Rachel Brown

Preliminary observations on the effects of a low-calcium diet on goats and kids. G. E. Glock, M. M. Murray and R. E. Glover. *J. Comp. Path. Therap.* **52**, 229–48(1939). Goats fed on flaked corn and bran with a min. amt. of hay developed symptoms characterized by loss of wt. and appetite with marked swelling of the jaws, lameness and paresis. The condition of the jaws and long bones resembled osteofibrosis. Blood analyses showed that the serum Ca was as low as 4.9 mg. per 100 cc. (normal mean 10.0) and that the morg. P varied but tended to be greater than normal (mean 6.2). The serum phosphatase was considerably increased. Several animals died in low-Ca tetany with serum Ca of approx. 5 mg. per 100 cc. The state of tetany was relieved by the addn. of $CaCO_3$ or vitamin D to the basal ration which was deficient in both. Rachel Brown

The destruction of vitamin C in cooking. H. R. Kanitz and E. Dammann. *Z. Hyg. Infektionskrankh.* **122**, 16–23 (1939).—The oxidation of ascorbic acid by the O of the air in cold and in boiling water, even in the presence of plant oxidase, is influenced by the pH and the ion content of the medium. Neutral salts like NaCl or Na_2SO_4 alone favor the destruction of ascorbic acid, but in mixts. with $NaHSO_4$ and $CaSO_4$ the oxidation is inhibited. The oxidation goes on quickly at alk. reactions but not at acid. $NaHSO_4$ and Na_2SO_4 combined inhibit the oxidation of ascorbic acid in cold and boiling distd. or tap water even in the presence of plant oxidase. The addn. of NaCl increases this action. Oxidases markedly accelerate the destruction of vitamin C in cold water. Rachel Brown

Vitamin B deficiency and leucopenia. F. Oestreicher and G. A. Overbeek. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 249–52(1939).—Rats weighing 25–30 g. were fed the following diet: carbohydrate, 68; casein, 18; olive oil, 9; cod-liver oil, 1; salt mixt., 4; and 1 mg. aneurin and 1 mg. lactoflavin. In rats on this diet the erythrocytes increased normally from the low level observed in early youth, but the leucocyte level remained low (around 8000/cc.). Addn. of nicotinic acid did not affect this leucopenia, but did prevent or cure diarrhea which was observed in many of the animals. E. Curzon

Certain aspects of mineral requirements. John H. Talbott and Frederick S. Coombs. *J. Am. Dietet. Assoc.* **15**, 631–8(1939).—A discussion. E. Curzon

Relation between thyroid and fattening results in swine. W. Zorn, H. Brüggemann and P. Moldrickx. *Z. Tierzücht. Züchtungsbiol.* **44**, 364–70(1939).—In studies on 157 fattening swine no correlation was found between the wt. and the I_2 content of the thyroid on the one hand and the food utilization on the other. No relation between these values and the fat-flesh ratio could be detected. E. C.

Thyroidectomy in swine for the purpose of increasing fat production. W. Zorn and H. Brüggemann. *Züchtungskunde* **14**, 376–88(1939).—If the thyroid glands were removed from pigs weighing 30–40 kg. and the animals were then fattened for about 90 days and slaughtered, an increase of about 14% in the percentage of fat in the carcass as compared with normal animals was found. Food utilization was poorer, however. No such effects were noted in swine thyroidectomized at a wt. of 60–70 kg. Thyroid glands implanted behind the ear of normal pigs were rapidly resorbed. E. Curzon

Formulas and tables for calculating the vitamin requirements of various animals. Paul Meunier and Yves Raoul. *Compt. rend. soc. biol.* **132**, 259–60(1939); cf. *C. A.* **33**, 2945[4]. L. E. Gilson

[Increase in] cholinesterase activity in blood serum and duodenum of beriberi pigeons. Wm. Antopol, Susi Glaubach and David Glick. *Proc. Soc. Exptl. Biol. Med.* **42**, 679–83(1939). L. E. Gilson

Influence of vitamin A on urea clearance in the rat. R. C. Herrin. *Proc. Soc. Exptl. Biol. Med.* **42**, 695–9(1939); cf. *C. A.* **33**, 4650[7].—In avitaminosis A there is a 23–77% decrease in urea clearance. It is a functional deficiency. Urine examn. and histological sections of the kidney show no morphological alterations. Feeding carotene to the deficient rats resulted in a 30–170% increase in urea clearance above the level in avitaminosis A. L. E. Gilson

Experiments on the antidermatitis component of the filtrate factor [of liver extracts] in rats. Paul György, C. E. Poling and Y. Subbarow. *Proc. Soc. Exptl. Biol. Med.* **42**, 738–40(1939); cf. *C. A.* **33**, 5899[9], 8710[9].—Crude salts of pantothenic acid were active in the cure of specific skin lesions and in promoting growth in rats fed a diet devoid of the filtrate factor. Autoclaving at pH 10 destroyed the activity of the prepns. L. E. Gilson

Vitamin E deficiency in dogs. H. D. Anderson, C. A. Elvehjem and J. E. Gonce, Jr. *Proc. Soc. Exptl. Biol. Med.* **42**, 750–5(1939).—Female dogs were kept on a mineralized evapd. milk diet low in vitamin E. Their pups showed a muscular dystrophy like that previously described in rats, guinea pigs and rabbits. In its early stages it was cured by synthetic α-tocopherol. L. E. Gilson

Cure and prevention of vitamin E-deficient muscular dystrophy [in rats] with synthetic α-tocopherol acetate. G. C. Knowlton, H. M. Hines and K. M. Brinkhous. *Proc. Soc. Exptl. Biol. Med.* **42**, 804–9(1939); cf. *C. A.* **33**, 8712[1]. L. E. Gilson

Vitamin K deficiency and prothrombin levels. Effect of vitamin K administration. Robert T. Tidrick, Frank T. Joyce and H. P. Smith. *Proc. Soc. Exptl. Biol. Med.* **42**, 853–7(1939).—In newly hatched chicks on a vitamin K-deficient diet the whole blood clotting time becomes pro-

longed when the prothrombin level falls to about 30% of the normal, and hemorrhages appear when it falls to about 10% of the normal. Large single doses (16 γ or more) of vitamin K correct the deficit almost completely in 6 hrs. and 8 γ produce the same effect in 18 hrs. A single dose of 1 γ produces a slight but noticeable effect. L. E. Gilson

Urinary elimination of trimethylamine during fasting. F. M. Chiancone. *Boll. soc. ital. biol. sper.* **14**, 560-1 (1939).—In white rats the elimination of trimethylamine increased markedly during fasting. Helen Lee Gruehl

Oxidation-reduction and tissue changes during a non-protein vitamin regime. M. M. Mir-Salimov. *J. méd., Ukraine* **9**, 49-59(in French, 58-9)(1939).—The addn. of vitamins A and D (fish-liver oils) and B (yeast) to a protein-free diet reduces the wt. loss in rabbits and prevents the development of hypochromic anemia, which is observed with rabbits on a vitamin-free, protein-free diet. Little change was observed in total and reduced glutathione (I) in the blood, but oxidized I showed a marked increase in the blood and organs. The introduction of vitamins to a protein-free diet has little effect on blood sugar and the glycogen content of the organs, but causes the anaerobic glucolysis of the skeletal muscles to rise to normal, while that of the liver is decreased further. No change in tissue respiration was observed. S. A. Karjala

Pathologo-anatomical changes in pregnant rabbits on a protein-free diet. M. K. Ventskovskiĭ. *J. méd., Ukraine* **9**, 421-8(in French, 427-8)(1939).—Rabbits placed on a prolonged protein-free diet do not become pregnant, and those placed on the diet immediately, or 8-10 days after mating, yield dead embryos. Extensive pathologo-anatomical lesions were observed in the placenta, liver, spleen, adrenals, kidneys, uterus and ovaries. No lesions were observed in the embryos. S. A. Karjala

Hemorrhagic adrenal necrosis in rats on deficient diets. Floyd S. Daft and W. H. Sebrell. *U. S. Pub. Health Repts.* **54**, 2247-50(1939).—D. and S. observed extensive hemorrhagic necrosis of the adrenal gland of rats on deficient diets. The condition appears to be due most probably to a deficiency in some unidentified dietary factor. These animals have not shown the purpura or bone marrow changes reported by other investigators in rats on diets deficient in various factors of the vitamin B complex. It appears unlikely that the hemorrhagic adrenal necrosis is part of the syndrome described as panmyelophthisis, although there is not sufficient evidence to prove conclusively that the 2 conditions are entirely unrelated. J. A. K.

Hemorrhagic cortical necrosis of adrenals in rats on deficient diets. A. A. Nelson. *U. S. Pub. Health Repts.* **54**, 2250-6(1939).—The hemorrhagic cortical necrosis of the adrenals and other lesions found in rats on diets deficient in some fraction of the vitamin B complex are described. The panmyelophthisis which Gyorgy, *et al.* (*J. Exptl. Med.* **66**, 579-602(1937)) found to occur together with hemorrhagic necrosis of the adrenals in a large proportion of their rats was found in only 1 rat in this series, and this animal had no adrenal lesions. Six references. J. A. Kennedy

Vitamin B_2 complex. III. Further studies on the growth-promoting factor in the liver extract. Ume Tange. *Bull. Agr. Chem. Soc. Japan* **15**, 65-70(1939)(in English).—See *C. A.* **33**, 4634[8]. Y. Kihara

The B vitamins and fat metabolism. III. The effects of vitamin B_6 upon liver and body fat. Gertrude Gavin and E. W. McHenry. *J. Biol. Chem.* **132**, 41-6(1940); cf. *C. A.* **32**, 9198[4].—The percentage of body fat in rats fed a fat-free diet is raised and the body wt. increased by feeding vitamin B_6 in conjunction with thiamine, riboflavin and choline. Nicotinic acid slightly augments the effect of vitamin B_6 upon body fat but not upon body wt. If choline is administered as a supplement, the percentage of fat in the liver is normal, an indication that choline is able to control the level of liver fat whether fat is supplied in the diet or whether it is formed by synthesis from carbohydrate when thiamine is furnished. The deposition of fat in the liver which results when thiamine is administered, is not prevented by vitamin B_6, riboflavin or nicotinic acid. A. P. Lothrop

Protein metabolism. XII. The conversion of ornithine into arginine in the mouse. Roger F. Clutton, Rudolf Schoenheimer and D. Rittenberg. *J. Biol. Chem.* **132**, 227-31(1940); cf. *C. A.* **34**, 141[2].—Mice of const. wt. were given *dl*-ornithine contg. 13.6 atoms % of stably bound D for 9 days. The isolated arginine from the total body proteins contained 0.88% D, an indication that at least 7.5% of the total arginine of the animals was derived from ornithine. This finding establishes the continuous conversion of ornithine into arginine by the mouse and the continuous replacement of arginine in the protein linkages by free arginine. A method is described for *the synthesis of ornithine contg. stably bound D* from α-pyridone. A. P. Lothrop

Deficiency of vitamin B_6. J. V. Landor. *Lancet* **1939, I**, 1368-70.—A pellagrous condition is described, which is apparently caused by deficiency of some factor of the vitamin B_2 complex. The condition is cured by yeast or marmite but not by nicotinic acid. E. R. Main

Response of nutritional macrocytic anemia to anahemin. Henry Foy and Athena Kondi. *Lancet* **1939, II**, 360-3.—Nutritional macrocytic anemia as seen in Macedonia responds to highly purified liver prepns., such as anahemin, as well as to cruder prepns. This is in contrast to cases reported in India (cf. Wills, Clutterbuck and Evans, *C. A.* **32**, 2627[1]). Large doses of the filtrate factor alone were ineffective for the cases in Macedonia. E. R. M.

Vitamins D_2 and D_3 in infantile rickets. A comparison of therapeutic efficiency. Noah Morris and Mary M. Stevenson. *Lancet* **1939, II**, 876-9.—The cryst. vitamins D_2 and D_3, given in amts. equiv. to 2000 I. U. daily, were equally effective in promoting healing of active rickets in infants and children. E. R. Main

Vitamin K lack in normal and sick infants. H. Dam, E. Tage-Hansen and P. Plum. *Lancet* **1939, II**, 1157-61; cf. *C. A.* **32**, 9223[3].—A moderate reduction in prothrombin content of the blood, observed in normal infants during the 1st week of life, is assocd. with a vitamin K deficiency which develops during the 1st few days after birth. In icterus gravis neonatorum, anemia neonatorum and hydrops congenita the prothrombin content is greatly reduced. It increases rapidly after oral administration of vitamin K together with bile salts. E. R. Main

Nutritional deficiency of vitamin K in man. Robert Kark and Eugene L. Lozner. *Lancet* **1939, II**, 1162-3.—A dietary deficiency state is described in which the prothrombin time, detd. by the method of Quick, Stanley-Brown and Bancroft (*Am. J. Med. Sci.* **190**, 501-11(1935)) is lengthened. Oral administration of vitamin K, without bile salts, was followed by a prompt return of prothrombin time to normal. E. R. Main

The influence of vitamin deficiencies on other diseases. John B. Youmans. *Ann. Internal Med.* **13**, 980-6(1939).—A review with 21 references. John T. Myers

Vitamin B_1 excretion on a varied intake. Margaret D. Wright and Audrey Z. Baker. *J. Hyg.* **39**, 638-42(1939).—The daily urinary excretion of vitamin B_1 by a healthy subject on a good mixed diet varied between 40 and 80 units, frequently between 60 and 80 units. One week on a low-B_1 diet reduced the daily excretion to about 13 units. On higher B_1 diets the vitamin calorie ratio was 0.3 or over, but on low-B_1 diet it was approx. 0.1 On the low-B_1

diets the excretion was 4.5% to 8.0% of the intake and on high-B_1 diets it was 10% to 12%. John T. Myers 1

Some effects of prolonged vitamin E deficiency in the rat. Archer J. P. Martin and Thomas Moore. *J. Hyg.* **39**, 643–50(1939).—In virgin female rats restricted to a diet deficient in vitamin E, a brown discoloration of the uterus results. The change was noted after 3–4 months and was striking after 12 months. Animals which had been pregnant gave similar results. The discoloration could be prevented but not cured by vitamin E. Vitamin E deprivation in male rats gave a similar discoloration in the seminal vesicles. The pigmentation was always limited to the muscular layers, and was due to the deposition of small granules in the smooth muscle cells, some of the cells being degenerated. Prolonged E deprivation produced degeneration of the kidney convoluted tubules in a high proportion of animals. 24 references. John T. Myers 2

The use of ascorbic acid (vitamin C) in the treatment of asthma. Araujo Cintra. *O Hospital* **16**, 961–85(1939).—A review of the literature and description of 22 different asthmatic cases treated with ascorbic acid. G. Nachod 3

The influence of ascorbic acid upon the liver function and the mutual relation between vitamins B_1 and C. I. Influence of ascorbic acid upon the pigment-excreting function of the liver. Osamu Murakami. *Japan. J. Gastroenterol.* **11**, 1–6(1939).—Feeding guinea pigs on a vitamin C-deficient diet results in a decrease in the amt. of bile and the pigment-excreting function of the liver. Repeated subcutaneous injections of small amts. of *l*- or *d*-ascorbic acid into the guinea pigs with C-hypovitaminosis removes the disturbances of the hepatic functions and increases the amt. of vitamin C in the liver. The action of *d*-ascorbic acid seems to be a little weaker than that of the *l*-ascorbic acid. **II. Influence of ascorbic acid upon the sodium santoninate-managing function of the liver.** *Ibid.* 7–12.—Repeated injections of 10 mg. of *l*-ascorbic acid to normal guinea pigs for 7 days accelerated the Na santoninate-detoxicating function of the liver. C-hypovitaminosis brings about a decrease in the detoxicating power of the liver. An increase in detoxicative power follows injection of *l*-ascorbic acid. The detoxicating function of the liver depends upon the amt. of vitamin C in the organ. **III. Influence of ascorbic acid upon the indole-detoxicating function of the liver.** *Ibid.* 13–23.—The detoxicating ability of the liver is lowered in case of C-hypovitaminosis. Administration of repeated small amts. of *l*-ascorbic acid to guinea pigs with C-hypovitaminosis restores the detoxicating function of the liver for indole. **IV. Mutual relationship between vitamins B_1 and C in the detoxicating function of the liver for indole.** *Ibid.* 24–30.—Addn. of a small amt. of vitamin B_1 markedly strengthens the effect of ascorbic acid in this case. **V. Effect of ascorbic acid on the peripheral blood vessels.** *Ibid.* 31–9.—*d*- or *l*-Ascorbic acid in a concn. of 50 mg. % and 100 mg. % markedly dilates the ear vessels of a rabbit. The vasodilatory action is only temporary. **VI. Mutual relationship between vitamins B_1 and C, regarding the action of the blood vessel.** *Ibid.* 40–8.—Addn. of a small amt. of vitamin B_1 to a low concn. of a soln. of *l*- or *d*-ascorbic acid markedly increases the vasodilatory action of ascorbic acid. Benjamin Prescott 4 5 6 7 8

The influence of creatinine upon the metabolism of carbohydrate. Osamu Murakami. *Japan. J. Gastroenterol.* **11**, 69–74(1939).—Intravenous injections of creatinine into normal rabbits have no influence upon the blood sugar of the animals, but injections of creatinine after administration of glucose promote the fall of the blood-sugar level of rabbits abnormally elevated. Intravenous and intraperitoneal injections of creatinine into rabbits and guinea pigs do not promote the formation of glycogen from glucose given. Benjamin Prescott 9

Synthetic α-tocopherol and nutritional muscular dystrophy. Steward G. Morris. *Science* **90**, 424–5(1939).—Six rabbits suffering from muscular dystrophy were given synthetic α-tocopherol in doses ranging from 17 to 65 mg. All animals were cured except the one receiving 17 mg. The lower limit for a single curative dose is about 20 mg. Felix Saunders

Action of certain hormones as dietary constituents. Casimir Funk and Ian Casimir Funk. *Science* **90**, 443–5(1939).—On a deficient diet female sex organs undergo a marked retrogression with cessation of estrus. Estrin in such cases shows evidence of definite activity. A more complete diet causes no retrogression and estrin activity is not noticeable. Dihydrostilbestrol exerts the same activity on both types of food. Testosterone cannot replace estrin as a dietary hormonal precursor. The sex organs of the male are more resistant to dietary deficiencies, the animals showing only retrogression along with a significant loss in wt. Testosterone and gonadotropic hormone (pregnant mare serum) produce a small but definite effect. Oral administration of estrin to females depresses food intake, while testosterone and less so the gonadotropic hormone in males produce the opposite effect. Felix Saunders

Control of experimental alcaptonuria by means of vitamin C. Robert R. Sealock and Hannah E. Silberstein. *Science* **90**, 517(1939).—Alcaptonuria can be produced in guinea pigs by feeding tyrosine. When 0.5 g. of *l*-tyrosine was fed with a basal diet which contained 0.5 mg. ascorbic acid there was an excretion of 20–50% of the theoretical amt. of homogentisic acid. After the addn. of 5 mg. of ascorbic acid to the diet there was only a trace of homogentisic acid in the urine. Human subjects on a diet practically free from ascorbic acid excreted homogentisic acid after ingesting tyrosine. The excretion of homogentisic acid could be prevented by taking ascorbic acid. Felix Saunders

Role of manganese in the biological synthesis of ascorbic acid. M. N. Rudra. *Nature* **144**, 868(1939); cf. *C. A.* **33**, 5478[8], 8695[5], 8721[3].—The hypothesis is advanced that the inability of the guinea pig and man to synthesize their requirement of ascorbic acid is due to the lack or insufficiency of Mn in their tissues. E. D. Walter

Influence of age on the requirement of vitamin A. J. T. Irving and M. B. Richards. *Nature* **144**, 908–9(1939); cf. *C. A.* **33**, 2190[3].—Rats were put on a vitamin A-free diet at weaning and given dosages of vitamin A varying from 1/5 to 3 international units daily. They were killed at different ages and their teeth exam'd. The results show that the vitamin A requirement increases with age, not only for tooth formation, but also to avert the other pathol. changes assocd. with vitamin A deficiency. E. D. W.

Vitamin A content of the livers of a hundred healthy dogs. R. G. Linton and A. Brownlee. *Nature* **144**, 978–9(1939).—The vitamin A content of the liver of 100 healthy dogs averaged 678 blue units per g. of liver tissue, with a medial figure of 153.5 and a range of 4.5 to 19,625. E. D. Walter

Use of sodium metaphosphate for prepn. of soft-curd milk (Schwartz, *et al.*) **12**.

Diet in Health and Disease. Edited by **Humphry Rolleston, and Alan A. Moncrieff.** London: Eyre & Spottiswoode, Ltd. 382 pp. 14s. Reviewed in *J. Am. Med. Assoc.* **114**, 84(1940).

F—PHYSIOLOGY

HOMER W. SMITH

Hypertrophy of certain essential organs during the increase in metabolism which accompanies acclimatization to the cold. Results on the plasticity and renewal of these organs. L. Chevillard and André Mayer. *Ann. physiol. physicochim. biol.* **15**, 411–31(1939); cf. *C. A.* **32**, 7539[6], 7540[3]; **33**, 8735[2].—Under conditions of increased caloric loss the mass of the liver of Norman rabbits (Gambais variety) increases less rapidly than the metabolism. A comparison between mice and rabbits reveals that the mass of the liver increases more rapidly when the initial metabolism is less intense. The mass of the heart, lungs and kidneys also increases, the increase varying for the different organs and for different breeds. This hypertrophy is due to an increase in the mass of the fundamental cellular constituents (H_2O, inorg. substances, proteins, lipides, carbohydrates), the relative concns. of which vary little.

Certain essential organs seem to be endowed with a remarkable plasticity. The apparently stable, fundamental constituents of the cells are probably renewed. An attempt has been made to est. the order of magnitude of this speed of renewal for certain organs and constituents.
Ruth Berggren

Metabolism of the heart. C. A. Lovatt Evans. *Edinburgh Med. J.* **46**, 733–49(1939).—A review with 29 references.
Rachel Brown

The relationship between salivary output and intestinal effects with carbaminoylcholine chloride (Lentin). A. Henry Craige, Jr. *J. Am. Vet. Med. Assoc.* **95**, 701–9 (1939).—In the dog the smallest dose of carbaminoylcholine chloride with a definite sialagogue action is also the smallest dose which augments motility and secretion in the small intestine. Parotid and intestinal secretions were augmented with 0.004 mg. per kg. R. Brown

The influence of varying copper intake on normal blood copper of Northumbrian sheep. A. Eden. *J. Comp. Path. Therap.* **52**, 249–57(1939). One hundred and fifteen sheep showed a blood Cu range of 0.029 to 0.128 mg. % with a mean of 0.071. The natural grazing had a Cu content of 7 to 10 p. p. m. of the dry matter. A range of 0.016 to 0.164 with a mean of 0.090 was found in sheep receiving a small supplement of heavy mineralized cake contg. sufficient Cu to double the daily intake. The addnl. Cu did not bring very low values up to the mean value of the controls. Animals receiving monthly anthelmintic treatment with $CuSO_4$ soln. showed a more uniform blood Cu level but no pronounced elevation of mean value. Year-old sheep had a slightly higher blood Cu level than older animals.
Rachel Brown

Phosphorus metabolism. The synthesis of phospholipides, phosphoproteins and nucleoproteins. D. Bocciarelli, A. Galamini and M. Ligori. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 512–17(1939).—The metabolism of P is followed in dogs by utilizing the P^{32} isotope which has a period of 14 days. Thus the distribution of ingested P^{32} and its utilization by various organs can be measured. The liver is found to be active in the formation of phospholipides while the intestines are high in contents of nucleoproteins and phosphoproteins. A. W. C.

The effect of implantations of the adrenal cortex on the development of the thyroid in chick embryos. M. L. Rokhlina and A. N. Studitskiĭ. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 171–4(1937).—Implantation of the adrenal cortex of rats into the chorio-allantoic envelope of 8-day chick embryos inhibited the development of the thyroid in the embryos, this inhibition being especially evident 12–14 days after incubation. S. A. Corson

The role of the cerebrospinal fluid in the regulation of the functions of the nervous system and of the organism. L. S. Shtern. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 205–7 (1937).—A short review dealing with the role of the hemato-encephalitic barrier in regulating the exchange of substances between the blood and the nervous system.
S. A. Corson

Humoral regulation of the functions of the liver. IV. Influence of the metabolites of the gastric mucosa on glycogenesis and bile secretion. S. Rapoport and N. F. Khodnia. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 208–12(1937).—Metabolites of the gastric mucosa of dogs or cats were obtained 3–4 or 18–48 hrs. after feeding and injected into the portal veins of the corresponding animals. Injection of the metabolites of the fundic part of the stomach obtained 3–4 hrs. after feeding led to an increase in the blood sugar, a decrease in liver glycogen and a retardation in the bile secretion. Metabolites of the gastric mucosa taken 18–48 hrs. after feeding were ineffective, while the metabolites of the pyloric part of the stomach gave contradictory results. S. A. Corson

Modification of the biological properties of preserved arterial blood. N. F. Khodnia. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 213–15(1937).—Plasma retained its biol. properties better than serum. S. A. Corson

Seasonal variations of the comb-growth response in white Leghorn capons. L. Waterman. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 263–4(1939).—The effect of 100 γ of androsterone on the comb growth of capons kept during the 5 days of the expt. in a room free from daylight and lighted electrically for 8 hrs. daily was detd. Results indicate that the reduced sensitivity of capons to male hormones during the summer season is due to a large extent to daylight. E. Curzon

The influence of castration on adrenal weight in female rats. L. Waterman. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 263(1939).—The adrenal wt. of 23 noncastrated 200-g. female rats averaged 66 ± 2.6 mg.; one week after castration the adrenal glands of 14 200-g. female rats averaged 49 ± 2.1 mg. E. Curzon

Hormone influence on the feather color of partridge-colored Leghorn cocks. O. Mühlbock. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 264–6 (1939).—The change in feather color of partridge-colored Leghorn cocks which is caused by estrogenic hormones is not affected by the simultaneous administration of large doses of testosterone propionate or of progesterone.
E. Curzon

The metabolism of calcium and phosphorus. C. I. Reed. *J. Am. Dietet. Assoc.* **15**, 667–74(1939).—A discussion. E. Curzon

The biological norm of the calcium-phosphorus relationships in the animal body. Carried out on the basis of practical cattle management. Max Nitsche. *Z. Tierzucht. Zuchtungsbiol.* **44**, 230–52(1939).—Studies on 11 rats (*Mus rattus*) show that the Ca-P content of the whole skeleton increases with age. The proportion of ash in an individual bone may differ from that in the whole skeleton; the increases with age will, however, be similar. The ash content of the rising submaxillary branch of the nose process (a nonspongy bone) of cattle and deer of varying ages and sex (including the fetus) was detd. The ash increased markedly in the fetus up to about the 7th month and a level of about 53%. Here it remained until about 3 weeks after birth. At one year the nose bone contained 60–61% of ash. In the 1–3-yr.-old period there was much fluctuation in the ash content of cattle owing to frequent neg. Ca-P balance. Alfalfa hay is a valuable cattle feed and has a good effect on bone ash.
E. Curzon

Glucolysis after phosphorylation in embryo extracts. O. Meyerhof and E. Perdigon. *Compt. rend. soc. biol.* **132**, 186–90(1939). Exts. of mouse and chick embryos prepd. by the special methods described readily converted a mixt. of Na pyruvate and hexose diphosphate into lactic and phosphoglyceric acids in the presence of cozymase and other necessary accessory substances. L. E. Gilson

Existence of an endocrine gland in the media of the renal arterioles. N. Goormaghtigh. *Proc. Soc. Exptl. Biol. Med.* **42**, 688–9(1939).—Preliminary work suggests that the afibrillar cells of the juxta glomerular app. have an endocrine function and regulate the tonus of the renal arterioles. L. E. Gilson

Recovery of vitamin C from the human bladder. Sol Sherry and Gerald J. Friedman. *Proc. Soc. Exptl. Biol. Med.* **42**, 707–9(1939); cf. *C. A.* **33**, 1372³.—When 0.5–30 mg. ascorbic acid was instilled into the human bladder 92–107% of it was present in the urine after periods of 1–5 hrs. No appreciable destruction occurred.
L. E. Gilson

Concentrating capacity of the kidney as revealed by in-

the administration of posterior pituitary ext. results in the formation of a more concd. urine than follows from the restriction alone. L. E. Gilson

Failure to recover pregnanediol glucuronidate in monkeys, rabbits and cats. U. Westphal and C. L. Buxton. *Proc. Soc. Exptl. Biol. Med.* **42**, 749–50(1939); cf. *C. A.* **33**, 8260³.—No pregnanediol glucuronate was found in urine of pregnant and normal female rabbits and cats. None was found in the urine of normal male and castrated female monkeys which were given injections of progesterone.
L. E. Gilson

Androgenic function of APL (chorionic gonadotropic

hormone)-stimulated ovaries in immature rats. R. R. Greene and M. W. Burrill. *Proc. Soc. Exptl. Biol. Med.* **42**, 761–4(1939). **Androgen production in normal intact and castrated immature female rats.** M. W. Burrill and R. R. Greene. *Ibid.* 764–6; cf. *C. A.* **33**, 7863[7].—Preliminary notes. L. E. Gilson 1

Blood pressure of pregnant rabbits and its response to pitressin. E. W. Page and Eric Ogden. *Proc. Soc. Exptl. Biol. Med.* **42**, 770–1(1939).—The response to pitressin was the same in pregnant and nonpregnant rabbits. L. E. Gilson 2

Changes in excretion of radioactive sodium and potassium and in carbohydrate stores twenty-four hours following adrenalectomy. Evelyn Anderson, Michael Joseph and Virgil Herring. *Proc. Soc. Exptl. Biol. Med.* **42**, 782–5(1939); cf. *C. A.* **33**, 7851[7].—Male rats 65 days old were used. Increased urinary excretion of Na, retention of K, lowered blood sugar and decreases in liver and muscle glycogen are detectable in 24 hrs. after adrenalectomy. L. E. Gilson 3

Localization of adrenal cortical hormones in the adrenal cortex of the cat. H. Stanley Bennett. *Proc. Soc. Exptl. Biol. Med.* **42**, 786–8(1939).—Preliminary. L. E. G.

Masculinization of adult female rabbits following injection of testosterone propionate. C. K. Hu and C. N. Frazier. *Proc. Soc. Exptl. Biol. Med.* **42**, 820–3(1939). L. E. Gilson 4

Utilization of pyruvic acid in eviscerated dogs. V. Capraro and E. Milla. *Boll. soc. ital. biol. sper.* **14**, 554–6(1939).—The viscera, particularly the liver, apparently were of little importance in removing lactic or pyruvic acid from the circulation. Helen Lee Gruehl

Formation of xanthuric acid from tryptophan in animals. F. M. Chiancone. *Boll. soc. ital. biol. sper.* **14**, 561–2 (1939). Helen Lee Gruehl

Effect of adrenal cortex extract on water-saline metabolism. F. Addarii and F. Scarlini. *Boll. soc. ital. biol. sper.* **14**, 563–5(1939).—This ext. increased water elimination and favored retention of Na and Cl. H. L. G. 5

Total and exclusive derivation of urea from arginine in birds. A. Clementi. *Boll. soc. ital. biol. sper.* **14**, 570–2 (1939); cf. *C. A.* **33**, 1800[8]. Helen Lee Gruehl

Problems of the chemical determination of the embryonic development. V. A. Dorfman. *Uspekhi Sovremennoĭ Biol.* **8**, No. 3, 367–89(1938); *Khim. Referat. Zhur.* **2**, No. 4, 62–3(1939).—A no. of theories are presented concerning embryonic development. Investigations are described on the biochem. processes in the egg (breathing) and a no. of physical-chem. indexes (oxidation-reduction potential, pH) are discussed. From the data it is concluded that the biochem. and the physical-chem. processes are not the same for different poles of the egg. W. R. Henn 6

Attempts to detect mucoprotein substances in the secretory product of the mammary gland in women, especially by the histochemical reaction with toluidine blue-gum sirup of Apathy. Jean Grynfeltt. *Arch. soc. sci. méd. biol. Montpellier et Languedoc* **20**, 278–82(1939).—Mucoproteins, produced by the cancerous breast, were not found in the secretions of the normal mammary glands of newborn infants, menstruating young girls, or pregnant, lactating or weaning women. Marion Horn 7

The variations in nitrogen compounds and proteins in the tissues of the aged and the action of cytotoxic antireticular serum on these variations. N. B. Medvedeva. *J. méd., Ukraine* **9**, 325–38(in French, 338)(1939).—Old age causes a reduction in sol. proteins and an accumulation of inert, insol. nonprotein-N (I) and noncoagulable substances in the liver, while an increase in I and in sol. protein, especially albumin, and products of protein decompn. are found in the heart and kidneys. The intestinal proteins are less sol. and less stable, and there is an accumulation of I, while the muscles and lungs contain large amts. of insol. protein and I. The skin is most resistant to old age. There is a tendency for a decrease in sol. protein and in its stability, but there is no accumulation of inert protein or products of protein decompn. There is an accumulation of protein and I in the brain, with an increased concn. of labile globulin. The injection of cytotoxic antimesenchymatic serum in these cases results in an increase in the amt. and stability of sol. protein, and elimination of insol. proteins and I, with a return of the concn. of protein fractions to values normal for adults. S. A. Karjala 8

Variations of the lipocytic coefficient with age. M. D. Gatsanyuk. *J. méd., Ukraine* **9**, 343–60(in French, 360)(1939).—The growth of rats from 3–4 months to old age (2 yrs.) is accompanied by an increase in cholesterol (I) in the brain, lungs, liver, kidneys, blood and muscle by 191.7, 39.6, 34.8, 33.0, 25.0 and 12.8%, resp., when the comparison is made with old under-nourished rats. In well-fed rats the increases in I are 81.9, 44.2, 57.0, 36.3, 69.9 and 40.7%, resp. During the period of 3–4 months to 1 yr. the fat acid (II) content of the blood, lungs, brain and kidneys falls 23.7, 26.2, 12.5 and 11.7%, resp., and increases 46.7 and 22.8%, resp., in the muscles and kidneys. In old under-nourished rats II falls 63.2, 33.9 and 24.7%, resp., in the brain, lungs and kidneys. In all of the organs of old well-fed rats an increase in II was observed; it amounted in the blood, liver, muscles, lungs, kidneys and brain to 306.6, 113.7, 168.5, 140.8, 99 and 49.1%, resp. The H_2O content fell with age in the brain and muscles, showed no change in the blood, and increased in the kidneys and lungs of well-fed old rats and in the liver of adult rats. The lipocytic coeff., I/II, increases during the young-to-adult and adult-to-old age transitions in the brain, blood, lungs and kidneys, and decreases in the liver and muscles. It falls in the blood, muscles, lungs and liver of old well-fed rats owing to the large increase in II, does not change in the kidneys, and increases in the brain. No correlation was found between the variations in H_2O content of the tissues and the variations in I/II. S. A. Karjala 9

Hemodynamics in persons of advanced age. II. I. M. Turovets. *J. méd., Ukraine* **9**, 477–83(in French, 483)(1939); cf. *C. A.* **33**, 2569[1].—A study of 21 subjects aged 90–130 yrs. indicated that basal metabolism and the minute and systolic vols. of the heart are lowered. There is a greater difference between the O_2 content of arterial and venous blood and the coeff. of utilization of O_2 is increased. A slight venous hypoxemia, sometimes accompanied by arterial hypoxemia, generally occurs. The blood content and blood circulation decrease. S. A. Karjala 10

A biochemical investigation of blood regeneration in donors. V. V. Koval'skiĭ, A. I. Kotnitskiĭ, O. V. Bogatyrchuk, M. F. Krasnetsova, N. D. Landa and E. O. Fialko. *Klin. Med.* (U. S. S. R.) **16**, 976–80(1938).—The normal K level of 18.2–22.4 mg. % in the serum of donors begins to rise 1 day after blood removal, and reaches a max. of 19.2–25.2 mg. % on the 7th–13th day. In the same period the K level of the plasma increases from 20.5 to 22.7 mg. %. No changes in Ca, Na or Mg were observed, so the changes in K cannot be due to an increased tissue permeability but must be due to erythrocyte destruction. The K/Ca ratio increases from the normal of approx. 2 to 2.4. Blood sugar falls 5–30.5% (av. 18.4%) after blood removal, and begins to increase only at about the 20th day. This decrease in sugar is considered to be due directly to the increase in K. The erythrocyte count falls immediately after blood removal but rises on the 14th–15th day. It then falls again on the 15th–20th day and begins to rise only some time after the 20th day. The hemoglobin content falls also on the 2nd–9th day, rises slowly and falls again on the 14th–20th day, closely paralleling the erythrocyte count. The protein content of the plasma falls from 1006–1086 to 860–940 mg. % N on the 3rd–10th day after blood removal, rises to 970–1050 on the 11th–20th day, and falls again to 898–978 mg. % N on the 21st–27th day. The residual N of the plasma increases from the normal 33 to 36 mg. % on the 1st–9th day, then decreases to 26 mg. % on the 9th–22nd day, followed by an increase to 32 mg. % by the 29th day. The amino acid content of the plasma shows fluctuations similar to those of the residual N. S. A. Karjala 11

The effect of blood transfusion on basal metabolism. V. D. Anchelevich. *Klin. Med.* (U. S. S. R.) **16**, 981-5 (1938).—The O content of the blood decreases until the 3rd day after transfusion, and then it begins to increase. In pernicious anemia the increase in O begins on the 2nd day. Reserve alkali and CO_2 in the blood increase after transfusion. No correlation was observed between the increase in hemoglobin and that of O in the blood.
S. A. Karjala

Glutathione in preserved blood. S. G. Gekhman and I. P. Vasovskiĭ. *Klin. Med.* (U. S. S. R.) **16**, 1002-6 (1938).—The total glutathione (I) of preserved blood falls 1-4 mg. % on the 1st day and then remains const. for 5-6 days, after which rapid decompn. occurs, resulting in the complete disappearance of I in 24-26 days.
S. A. Karjala

Muscle protein of herring. Saburo Wakamatu. *J. Agr. Chem. Soc. Japan* **15**, 915-20(1939). The muscle of herring contained 4.03% of H_2O-sol. N, 9.03% of 0.2% KOH-sol. N, 2.24% of 70% alc.-sol. N and 8.19% of 10% NaCl-sol. N. The muscle was extd. with H_2O, alc. and ether. The N distribution of the residue was: total N 12.52, amino N 7.56, basic N 3.92, ammonia N 0.41 and melanin N 0.63%. From the hydrolyzates of the protein, cystine 0.57, tyrosine 2.42, glutamic acid 9.86, alanine 2.84, leucine 12.51, proline 2.63, phenylalanine 3.37, serine 1.48, aspartic acid 3.50, histidine 2.35, arginine 5.17, lysine 12.11, tryptophan 1.13 and valine 1.70% were isolated; they were calcd. as moisture- and ash-free protein. No glycine was found. From the ext. of 1 kg. of the muscle, creatine 2.03, creatinine 0.26, methylguanidine 0.33, hypoxanthine 0.51 g. and xanthine trace were isolated. In the ext. of 1 kg. of the muscle, from which the bloody colored parts were removed, 0.27 g. of the Ba salt of inosinic acid and 0.90 g. of taurine were found. In 1 kg. of the muscle protein, which was prepd. by extg. the muscle with H_2O to remove the ext., 0.757 g. of methylguanidine, 0.814 g. of hypoxanthine and a trace of xanthine were isolated. Y. Kihara

Acid-soluble phosphate compounds in intestinal mucosa at rest and during resorption. Einar Lundsgaard. *Z. physiol. Chem.* **261**, 193-208(1939). —After 24 hrs' fast and under amytal anesthesia, rat intestinal mucosa contains 459 (440-488) mg. of acid-sol. P per 100 g. dry wt. Of this, an av. of 29% is inorg., 35% is readily hydrolyzable and 36% is hydrolyzable with difficulty. Cat and rabbit intestinal mucosa are similar. During glucose resorption in rats, the inorg. P drops to 23%, the readily hydrolyzable fraction increases to 38% and the total is unchanged. Cat mucosa shows no definite change. During fructose resorption by rats the inorg. P falls to 16%, the readily hydrolyzable P rises to 52% and difficultly hydrolyzable falls to 32% with a possible slight rise in total acid-sol P. Corresponding changes occur in cat and rabbit mucosa but are less pronounced. The changes in P fractions produced by resorption are local in the rat intestine, only those parts of the mucosa participating showing them. The glycogen contents are unchanged during resorption. Killing the animal by KCN injection does not alter the relations within 1-1.5 min. This preliminary observation makes it doubtful that the process of phosphorylation and dephosphorylation is rapid enough to account for the rate of resorption of fructose. Milton Levy

Chemical transformation of triosephosphoric acids during glucolysis. H. Jost and H. Linde. *Z. physiol. Chem.* **261**, 225-39(1939).—Glyceraldehydephosphoric acid (I) is converted to lactic acid by fresh muscle exts. more rapidly than is dihydroxyacetonephosphoric acid (II). The latter must first be converted to hexosediphosphoric acid (III) which then is changed to I in order to form lactic acid. I is the probable direct precursor of phosphoglyceric acid in the ext. In dialyzed muscle ext. the formation of III from I and II (aldolase action) is demonstrable with racemic II although its formation from I or II alone is inhibited because of inactivation of the isomerase which converts II to I. The accumulation of III in muscle juices and exts. depends on the fact that the primary split product, II, is not converted into I sufficiently rapidly for dehydrogenation and accumulates to an extent consistent with the equil. between II and III. 1
Milton Levy

Sex hormones and related substances. (Sterols). XIII. Cholesterol formation in the animal. Wilhelm Dirscherl and Hans Traut. *Z. physiol. Chem.* **262**, 61-86(1939); cf. *C. A.* **33**, 2901[8].—Male white mice were fed oats. Their contents of digitonin-precipitable substances varied between 0.29 and 0.37% (mean 0.32%) of the body wts. and their daily excretion was 1.1-1.6 (mean 1.3) mg. above their intake. Cholesterol is therefore synthesized in the body. The sterols of the digitonide average 1 double bond per mol. Feeding of sec. Bu esters of stearic, oleic and linoleic acids or of sec. BuOH did not increase the sterol synthesis. No indication of sterol synthesis from fat acids was found. Milton Levy 2

Influence of estrogen on the electrolyte pattern of the immature rat uterus. N. B. Talbot, Oliver H. Lowry and E. B. Astwood. *J. Biol. Chem.* **132**, 1-9(1940); cf. *C. A.* **32**, 6715[5]. Six hrs. after administration of a single dose of estrogen to stimulate its growth, the extracellular phase of the immature rat uterus swells 50-75% while the cells increase only 1/3 as much. The cells take on their normal quota of K but definitely less than their quota of P and probably of solids so that there is an increase in the K P ratio. This is followed during the next 24 hrs. by a phase characterized by marked cell growth during which the cells take up approx. normal amts. of cell constituents. 3 4
A. P. Lothrop

The picric and picrolonic acid precipitates of gonadotropic extracts. Fritz Bischoff. *J. Biol. Chem.* **132**, 35-9 (1940); cf. *C. A.* **32**, 3474[1]. Picric and picrolonic acids completely ppt. the pituitary gonadotropic hormone and inactive material at about pH 3. It dissolves at pH 4.5 while some of the contaminating proteins are still insol. The insol. ppts. or the sol. exts. retain their activity when assayed with Cu to delay resorption or when administered simply in divided doses, 5 times instead of once daily. This observation shows that the weak response to the picrolonic acid ppt., when administered in the conventional assay, need not be explained on the basis of a reversible chem. inactivation. 5
A. P. Lothrop

Inheritance effect of exercise on the phospholipide and cholesterol content of muscle. W. R. Bloor. *J. Biol. Chem.* **132**, 77-82(1940); cf. *C. A.* **31**, 6716[6].—Muscles of rats exercised through the 2nd and 3rd generations show large increases in phospholipide and especially in cholesterol in addn. to hypertrophy. These findings seem to indicate that exercise through several generations may result in increased phospholipide and cholesterol content of muscle. There was an increase in the cholesterol content of all the muscles examd. and in the phospholipide content of all but the heart and diaphragm. A. P. L. 6 7

Colloidal sulfur-polysulfide mixture. Absorption and oxidation after oral administration. Harry Greengard and Jean Rea Woolley. *J. Biol. Chem.* **132**, 83-9(1940). —Orally administered colloidal S in doses of 500-750 mg. is completely absorbed, oxidized and excreted in the urine as sulfate, recovery being quant. in most cases. The absorption and elimination are very rapid, the urinary sulfate increasing markedly within 2 hrs. Probably less than 10% escapes oxidation. If 100-mesh powd. S is substituted, absorption occurs after 8-16 hrs. at which time it is probably in contact with the bacteria in the lower bowel. 8
A. P. Lothrop

The relation of urea and glycine to creatine synthesis. R. B. Fisher and A. E. Wilhelmi. *J. Biol. Chem.* **132**, 135-46(1940); cf. *C. A.* **31**, 7979[8].—The available evidence does not require the hypothesis that urea and glycine together are precursors of creatine in muscle tissue. No increase was observed in controlled expts. on the effect of injecting large amts. of these substances on the creatine content of rat muscle. There was no detectable synthesis of creatine when isolated rabbit hearts were perfused with urea and glycine under the same conditions in which a quant. conversion of arginine to creatine has been demonstrated. Reasons are adduced for thinking that investigations into the effect of administering 9

amino acids and other substances on the creatine content of muscle or on the rate of excretion cannot provide evidence about creatine precursors in the body. Cf. Beard and Pizzolato, *C. A.* **32**, 7126[1]. Forty-three references. A. P. Lothrop

The increase in phospholipide and total phosphorus metabolism of the kidney following the administration of ammonium chloride with radioactive phosphorus as an indicator. Louise Harris Weissberger. *J. Biol. Chem.* **132**, 219–26(1940).—NH_4Cl acidosis brings about an increase in the vol., acidity, total P and radioactive P content of the urine and an increased P turnover in the kidney phospholipide, in the whole kidney and in the blood. These findings lend support to the view that the kidney phospholipide is concerned in the regulation of blood and body acidity by renal excretion of acid phosphate and explain the increased turnover in kidney phospholipide early in fat absorption. The rats were fed Na_2HPO_4 3 contg. radioactive P with and without NH_4Cl. A. P. Lothrop

The metabolism of creatine and creatinine. III. Formation of creatine by isolated rat tissues. Zelma Baker and Benj. F. Miller. *J. Biol. Chem.* **132**, 233–7 (1940); cf. *C. A.* **33**, 8658[7].—Isolated rat kidney produced 4–8 mg. of creatine per 100 g. and liver 1.2–3.2 mg. in a 4-hr. incubation period in Ringer-phosphate or bicarbonate medium with no added substrate. These 4 represent approx. 10–30% increases. The process of creatine formation is apparently enzymic in nature. It is heat-labile and is inhibited by cyanide and by anaerobiosis. No significant increases were found in cardiac, skeletal and intestinal muscle, brain, testis and spleen. The specific, enzymic method of Miller, *et al.* (*loc cit.*) for the detn. of creatine was used. A. P. Lothrop

Experimental tumorigenesis with subcutaneous tablets of estradiol. Alexander Lipschütz and Luis Vargas, Jr. *Lancet* **1939**, I, 1313–18; cf. *C. A.* **33**, 2956[6].—Uterine 5 and extra-uterine tumors produced in guinea pigs by introducing 20-mg. tablets of estradiol under the skin are similar to those produced by injections of follicular hormones over a long period. The continuous absorption and flow from the tablets enhance the tumorigenic action of estradiol. E. R. Main

Biological effects of the synthetic estrogen hexestrol: 4,4′-dihydroxy-γ,δ-diphenyl-*n*-hexane. N. R. Campbell, E. C. Dodds, W. Lawson and R. L. Noble. *Lancet* **1939**, II, 312–13.—Hexestrol (I) stimulates the mammary glands 6 and sensitizes the uterus of the ovariectomized rabbit to the action of progesterone. In the rat, implantation is prevented, body growth is reduced and the gonads become atrophied after prolonged administration. The increase in wt. of the uterus of immature rats is approx. 7 the same as that produced by stilbestrol (II). When assayed by injection into ovariectomized rats, I was more active than II and both were 2–3 times more active than estrone. When given by mouth or applied intravaginally the activity of I was about equal to that of II. E. R. M.

Antitumorigenic action of progesterone. Alexander Lipschütz, Ruperto Murillo and Luis Vargas, Jr. *Lancet* **1939**, II, 420–1.—The production of uterine and extra-uterine tumors by estradiol benzoate (I) in castrated fe- 8 male guinea pigs is prevented to a large extent by simultaneous injections of progesterone in a dosage 150 times greater than that of I. E. R. Main

Stilbestrol and anhydro-oxyprogesterone. Their effects on menstruation and lactation. Robert Wenner and Karl Joël. *Lancet* **1939**, II, 688–91.—Administration of 25 mg. stilbestrol (I) by mouth, or 15 mg. given intramuscularly, was required to produce proliferation of a resting or atrophic endometrium. Administration of 50–60 9 mg. produced glandular cystic hyperplasia. The stage of transformation and menstruation following proliferation can be produced by oral administration of 500–600 mg. anhydro-oxyprogesterone. Lactation was either prevented or inhibited by oral administration of 5–15 mg. I. E. R. Main

Antitumorigenic action of testosterone. Alexander Lipschütz, Luis Vargas, Jr., and O. Ruz. *Lancet* **1939**, II, 867–9.—Administration of testosterone propionate (I) simultaneously with estradiol benzoate (II) prevents the development of uterine and extra-uterine fibroids in castrate guinea pigs when the amt. of I given is 12 times that of II. This amt. of I also prevents the increase in uterine wt. and the formation of atypical growth of the endometrium caused by II. E. R. Main

The new endocrinology. I. The pituitary. E. C. Dodds. *Lancet* **1939**, II, 800–2. **II. Chemistry of the sterols.** *Ibid.* 844–5. **III. The male sex hormone.** *Ibid.* 894–6. **IV. The female sex hormone.** *Ibid.* 953–4. **V. The corpus-luteum hormone.** *Ibid.* 998–9. **VI. Diagnostic value of urinary hormones.** *Ibid.* 1038. **VII. The suprarenal.** *Ibid.* 1087–9. E. R. M.

Effect of estrogens on the urinary volume. E. P. Sharpey-Schafer and I. Schrire. *Lancet* **1939**, II, 973–4.—Intramuscular injections of estradiol benzoate, in doses of 100,000 I. B. U. daily for 10 days, caused no detectable change in urinary vol. in women before or after the menopause, in castrated women or in men. E. R. Main

Neutralization of action of heparin by protamine. Erik Jorpes, Pehr Edman and Torsten Thaning. *Lancet* **1939**, II, 975.—The inactivation of heparin by protamine, reported by Chargaff and Olson (*C. A.* **32**, 1313[4]), is confirmed. The effect is demonstrable *in vitro* and *in vivo*. For administration to man, 35–60 mg. of protamine-SO_4 in a 2% soln. in dil. HCl, adjusted to pH 2.7 and sterilized by autoclaving, is injected intravenously. An amt. of protamine which represents 40–70% of the amt. of heparin injected is required to neutralize the effect of heparin. E. R. Main

Comparison of the effects of stilbestrol and estrone on the mammary tissue of castrated female rats. Eric Jacobsen and S. Skaarup Christensen. *Acta Path. Microbiol. Scand.* **16**, 359–64(1939).—Stilbestrol had a stimulating effect on the mammary tissue of 63 castrated female rats, qualitatively similar to that of estrone. 13 references. J. T. Myers

Effect of estrogen on bones, joints and ligaments of castrated guinea pigs. Charles J. Sutro and Leo Pomerantz. *Arch. Surg.* **39**, 992–1000(1939).—Castrated male guinea pigs can be feminized by injections of estrogens as revealed by enlargements of the nipples and formation of areolae. The ligaments of the symphysis pubis, especially the posterior ones become hypercellular, increase in thickness and invade the interpubic cartilages and posterior cortexes of the pubic bones. In some instances there were secondary degenerative changes in the interpubic cartilages. Even transplanted segments became hypercellular if sufficient estrogen was given. No other bones or ligaments showed changes. Guinea pigs weighing about 400 g. were used. The expts. lasted 28–80 days and the total amt. of estrogen administered was 12,000–60,000 rat units. 13 references. John T. Myers

Action of the orchidic hormone on the liver glycogen. Giacomo Fichera. *Arch. ital. med. sper.* **4**, 39–44(1939).—Injections into healthy fasting rabbits of 1 mg. testosterone propionate per kg. body weight cause a remarkable decrease of the liver glycogen (on the av. 4.16 mg.). Either the orchidic hormone attacks the hepatic cell directly or it stimulates the elaboration of glycogenolytic hormones from other endocrine glands. George Nachod

The effect of crystalline corpus luteum hormone, progesterone, on the ovaries and related endocrine organs. Charles Mazer and S. Leon Israel. *Am. J. Obstet. Gynecol.* **38**, 625–31(1939).—In doses of 0.5 mg. thrice weekly for 9.5 weeks, progesterone, unlike impure corpus luteum hormone, did not inhibit follicular growth, ovulation and luteinization in the normal adult rat. Larger doses were inhibitory in all respects and therefore considered unphysiol. J. Pinchack

The effects of extracts of normal and abnormal thyroids on the rabbit heart and liver. Joseph B. Wolffe. *Western J. Surg., Obstet. Gynecol.* **47**, 638–45(1939).—U. S. P. thyroid ext. administered in daily doses of 1.5 g. for 10 weeks had but a slight effect on the heart and liver of 6 normal rabbits. But exts. from diseased human thyroids produced definite electrocardiographic changes in approx.

50%, and histopathological changes in the myocardium and liver in approx. 70% of the animals injected. These effects appeared to be reversible and varied with the type of diseased thyroid used. J. Pinchack

Influence of anticoagulants on the proportions of elements in the blood. V. Chorine. *Ann. inst. Pasteur* **63**, 213–56(1939).—The effects of anticoagulants on the various elements, sugar and proteins in the blood are described. Benjamin Prescott

The supposed optical inactivation of *d*-tartaric acid by the pancreas. Carl Neuberg and Elisabeth Peiser. *Enzymologia* **7**, 228-30(1939)(in German).—Pancreas tissue does not racemize *d*-tartaric acid. F. S.

Citric acid in muscular respiration. Jacques Thomas. *Enzymologia* **7**, 231-8(1939)(in French).—The formation of malic acid from oxalacetic acid is of the same order whether the conditions are aerobic or anaerobic. This fact excludes the possibility of passage through the cycle of Krebs and Johnson (*C. A.* **31**, 8655[6]) in which O is necessary for the transformation of citric acid into malic acid. Furthermore, the yield of malic acid is of the same order in the presence of malonate in aerobiosis, a fact which is equally at variance with the mechanism proposed by K. and J., since the transformation of citric acid into malic acid would be blocked at the succinic acid stage. The formation of dinitrophenylhydrazones shows that, in the presence of arsenite, malic, fumaric and succinic acids are transformed into oxalacetic acid and must be considered as forming a part of a homogeneous system where each constituent is transformed easily into the other. Citric acid cannot be considered a constituent of the system for it is not transformed rapidly into a C_4 acid and consequently if it were a part of the cycle it would slow down the rhythm of the exchange. The catalytic effect of the C_4 acids is shown definitely in the first 10 min. of respiration, whereas citric acid does not begin to show its catalytic effect for 1 hr. If the citric acid acted as a catalyst it would be maintained in a const. amt. in muscle, a fact which could not be verified, so that citric acid must be considered as a substance being metabolized by the tissues rather than a catalyst of respiration. The argument that the Krebs theory is supported by the fact that injection of succinic, malic or fumaric acid leads to secretion of citric acid in the urine loses its value because other acids which do not take part in the respiratory cycle will produce the same effect. Citric acid is probably formed in the kidney. Felix Saunders

Comparative study of the metabolic effects of testosterone propionate in normal men and women and in eunuchoidism. Allan T. Kenyon, Kathryn Knowlton, Irene Sandiford, F. C. Koch and Gertrude Lotwin. *Endocrinology* **26**, 26–45(1940); cf. *C. A.* **32**, 7987[6,8].—Intramuscular injections of 25 mg. of testosterone propionate, daily or twice daily, in a eunuchoid, produced reduction in the urinary excretion of N, Na, K and Cl, together with a gain in wt., due largely to water held in assocn. with the salts and water retained. A considerable reduction in the urinary excretion of inorg. P accompanied that of the other constituents. During recovery Na, Cl and water were rapidly lost from the body, inorg. P and K less rapidly and less completely, while N stored was retained in great part for weeks. Two normal young men responded the same as the eunuchoids, except that the 0.03 g. of N retained per kg. per day, during the period of max. effect, was half that of the eunuchoids. One normal young woman responded essentially as the eunuchoids and the normal men. The second young woman showed a definite reduction in the urinary excretion of inorg. P but otherwise distinctly less evidence of a testosterone propionate effect. The concn. of urea and nonprotein N in the blood was definitely reduced by such treatment, while those of hemoglobin, plasma proteins, and serum Na, K and Cl were unaffected. The reduction in urinary electrolyte excretion, studied in the eunuchoid, was unaccompanied by important changes in urinary NH_3, pH, bicarbonate or concn. of titratable acid. Creatine excretion, in the eunuchoid, intensified by ingestion of creatine, was substantially reduced by the androgen and increased during recovery. Percutaneous administration of 25 and 50 mg. daily of testosterone in an ointment, in the eunuchoid decreased the urinary excretion of N. The basal metabolic rate, fasting R. Q., pulse rate and blood pressure of the normal subjects were not conspicuously affected by testosterone propionate. The basal metabolic rate of the eunuchoid was slightly increased; the pulse rate and blood pressure were unaffected. The 102.7–252.2 g. of protein estd. as retained by these subjects is not accounted for by increases in the bulk of genital tissues and represents deposit of new material elsewhere in the body. This retention, together with the reduction in the urinary excretion of inorg. P, K and creatine points to a somatropic influence of androgens and provides a clue to the explanation of unusual body growth accompanying precocious puberty. Felix Saunders

Tolerance of male and female mice respectively to estrogens and androgens. Charles D. Kochakian. *Endocrinology* **26**, 54–60(1940).—Each sex of the Little dba mice was better able to tolerate the "sex hormone" of the opposite sex. Testosterone propionate in daily doses of 0.4 and 0.2 mg. was not fatal but caused a decrease in gain in body wt. in the males. Estradiol dipropionate in doses of 0.25 and 0.10 mg. per day killed more females than males. Testosterone propionate added to the estrogen partially nullified its fatal effects. Testosterone propionate caused a definite and striking loss of hair in the male mice but had only a slight effect in the females. Felix Saunders

Composition of bones of mice receiving estrogens and androgens. John H. Wentworth, Paul K. Smith and Wm. U. Gardner. *Endocrinology* **26**, 61–7(1940).—The continued administration of large doses of estradiol benzoate to mice produces significantly higher concns. of inorg. substances in the femurs and pelves than in control mice or mice receiving testosterone propionate or estradiol benzoate plus testosterone propionate. The ratio of Ca to P in the femurs, but not in the pelves, of the mice receiving estradiol benzoate is significantly higher than in other groups. The higher ash content of the untreated females as compared with the untreated males indicates the influence of the animal's own hormones on skeletal growth. Felix Saunders

Mechanism of estrin therapy in the relief of dysmenorrhea. Somers H. Sturgis and Fuller Albright. *Endocrinology* **26**, 68–72(1940).—The course of estrin therapy should be started about the 6th day of the cycle and should be of the order of magnitude of 1.5 mg. of estradiol benzoate given intramuscularly every 3 days for 6 injections. Such therapy prevents the formation of a secretory endometrium presumably because of an inhibitory action of estrin on gonadotropic hormones and hence on ovulation. Felix Saunders

Relation of hyperemia to the action of estrin. Oscar Hechter, Maurice Lev and Samuel Soskin. *Endocrinology* **26**, 73–9(1940).—The effects of estrin can be divided into 2 groups (*a*) those specific actions of estrin which do not depend on hyperemia, and (*b*) those actions which are secondary to the production of the hyperemia, and which are assocd. with the acetylcholine-liberating action of estrin. Distention is dependent upon hyperemia since this effect is inhibited by atropine and duplicated by yohimbine. Distention may depend in part on the specific effect of estrin on the uterine cells, since some distention occurs when the hyperemic effect of estrin is inhibited by atropine. Distention is not always assocd. with hyperemia and *vice versa*. The accumulation of tissue water is due mainly to the specific action of estrin. Although hyperemia plays a role in this water accumulation, it is slight as compared to the direct action of estrin on the uterus. Felix Saunders

Experimental studies on the menstrual cycle of the baboon (Papio porcarius). VI. The effect of progesterone upon the first part of the cycle in normal female baboons. Joseph Gillman. *Endocrinology* **26**, 80–7 (1940).—The normal adult female baboon, when given progesterone in the first or turgescent part of the cycle, exhibits specific perineal reactions which may or may not

be accompanied by bleeding at the end of 4–7 days after progesterone administration. The perineal reaction consists of a sudden deturgescence when the sex skin may become completely absorbed. The min. quantity of progesterone necessary to produce this effect is 3 mg. Bleeding occurs if a single dose of 20 mg. is used and is pptd. on the 5th day after the injection when the perineal swelling has reached its lowest ebb. Doses smaller than 20 mg. produce deturgescence without bleeding. The 2 reactions, deturgescence with or without bleeding, permit an easy and accurate assay of progesterone uncomplicated by operative procedures. Felix Saunders

Influence of various physiological substances on the glycogenolysis of surviving rat liver. H. P. G. Seckel. *Endocrinology* **26**, 97–101(1940); cf. *C. A.* **33**, 1380⁹.—Rat liver glycogenolysis, as it proceeds in surviving tissue slices suspended in a buffered salt soln., is inhibited by large doses of cortical hormone (eschatin) added *in vitro*. The degree of inhibition averaged 41% for a 60-min. interval and a concn. of 6 units per 5 cc. In female rats the results were influenced by the hormonal tides of the sexual cycle. The inhibitory effect on hepatic glycogenolysis of cortical hormone is greater than that of insulin added *in vitro* and cannot be increased by combining the 2 hormones. One essential function of the cortical hormone is an inhibition of the glycogenolytic enzyme of the liver cells. Felix Saunders

Metabolism of nitrogen, sulfur and glutathione in thymectomized albino rats. Marta Sandberg, David Perla and Olive M. Holly. *Endocrinology* **26**, 102–6(1940).—After thymectomy urinary N excretion increases progressively but fecal N excretion remains unchanged. Exogenous and endogenous S metabolism is disturbed. Total urinary S and neutral S excretion increases. Fecal S, inorg. and ethereal sulfate excretion remains unchanged. Total glutathione in the blood of thymectomized rats rises slightly, but begins to return to normal 6 weeks after operation. A drop in reduced glutathione develops more slowly but persists longer. The main disturbance is in oxidized glutathione, which rises considerably after operation. After 18 weeks all glutathione values have returned to normal. Felix Saunders

Relation between thymus and sexual organs. Hugo Chiodi. *Endocrinology* **26**, 107–16(1940).—See *C. A.* **33**, 706⁸·⁹. Felix Saunders

Output of protein metabolism hormone of the pituitary anterior lobe. Karl E. Paschkis and Annie Schwoner. *Endocrinology* **26**, 117–22(1940).—Protein feeding is followed by the excretion of a factor in the urine which, when injected into rats, produces a decrease of blood urea N and of blood amino N. This factor is not present in the urine after a protein-free carbohydrate-fat diet. The same reaction to injection of urine after protein intake is obtained by injecting alk. exts. of the pituitary. Protein feeding is the adequate stimulus for the secretion of this hormone. Felix Saunders

Effect of estrin on the anterior pituitary of male rats after pituitary stalk section. Unto U. Uotila. *Endocrinology* **26**, 123–8(1940).—Large doses of estrin injected into male rats act on the anterior pituitary without the mediation or any modifying effect of the pituitary stalk. This is shown by the following facts: (*a*) the anterior pituitary hypertrophies and shows the same cytological changes in rats which have received estrin whether the stalk be intact or severed; (*b*) estrin suppresses the secretion of gonadotropic hormones in stalk-cut and intact male rats to an equal extent, as shown by the appearance of a marked atrophy of the testes and seminal vesicles in both groups. The adrenals hypertrophy equally after estrin treatment in intact and stalk-sectioned animals, an indication that estrin also affects the corticotropic function of the anterior hypophysis without any mediation or modification of the pituitary stalk. Estrin acts directly on the anterior hypophysis. This action is a part of the humoral control of the basic secretory rhythm of the gland. F. Saunders

Regulation of thyrotropic function by thyroxine after pituitary stalk section. Unto U. Uotila. *Endocrinology* **26**, 129–35(1940).—The thyrotropic function of the anterior hypophysis has a basic secretory rhythm which is for the most part controlled humorally by variations in the thyroxine level without the mediation of the hypothalamo-hypophyseal pathways. Hypothalamic impulses through the pituitary stalk, or to a lesser extent the cervical sympathetics, can under certain conditions modify this basic thyrotropic secretory rhythm. F. Saunders

Effect of thyrotropic hormone on pregnant rabbits. Beatrice Whiteside. *Endocrinology* **26**, 136–41(1940).—Pregnant rabbits were injected with thyrotropic hormone. In every case the gestation was interrupted, either by abortion or by the death of the fetuses. The organs of the fetuses were extremely degenerated. The thyroid of the mother was hyperplastic. Her ovaries showed signs of degenerative changes. Felix Saunders

Treatment of pituitary dwarfism with growth hormone. Joseph M. Looney. *Endocrinology* **26**, 163–6(1940).—A case report. Felix Saunders

Response of the ovaries to gonadotropic extracts in splenectomized rats. Frederick E. Emery, Thaddeus J. Bugelski and Edward L. Schwabe. *Endocrinology* **26**, 167–9(1940).—Rats splenectomized at approx. 30 days of age were injected for 30 days with antuitrin-S, APL and pituitary gonadotropic ext. The wts. of the ovaries and uterus at the end of treatment were not significantly different from those of control rats. Felix Saunders

Correlation of pituitary and spleen in experimental and control mice. J. M. Twort and R. Lyth. *Endocrinology* **26**, 170–1(1940).—Data relating to the wt. of spleens and approx. superficial area of the pituitary gland in over 4000 mice and the pituitary dry wt. of over 2500 mice were analyzed to det. whether the wt. of the spleen influenced the size or wt. of the pituitary gland. When mice with large spleens were considered there was a definite pos. correlation between the 2 glands. There was a slight neg. correlation in tumor-bearing mice. F. Saunders

Morphological changes in female mice receiving large doses of testosterone. Hans Selye. *J. Endocrinology* **1**, 208–15(1939).—Daily administration of 5 mg. of testosterone propionate to adult female mice for 20 days causes a decrease in the total size of the ovaries, disappearance of normal corpora lutea and marked follicle stimulation with the formation of follicular and occasionally of corpus luteum cysts. The adrenal cortex becomes atrophic, the hypophysis decreases in wt. without showing any indication of degranulation of the anterior lobe chromophile cells. The kidneys are markedly changed but the liver and spleen show no changes. These large doses do not produce the toxic actions of estrogen overdosage. Felix Saunders

Metabolism of glutathione. H. Waelsch and D. Rittenberg. *Science* **90**, 423–4(1939).—Glycine contg. 1.18 atoms % N^{15} excess was fed to rats. After 2 hrs. the concn. of N^{15} in the reduced glutathione (GSH) of the liver and the intestine, together with the N^{15} content of the protein glycine and the nonprotein N of these organs was detd. Since the speed of deamination of glycine is slow the N^{15} is probably all in the glycine portion of the GSH. The concn. of N^{15} in the glycine of the liver GSH is 0.27 atom % and the min. rate of turnover of GSH is 22.3% (intestine 9.6%) in 2 hrs. In the same period only 1.6% (intestine 1.5%) of the protein glycine of the liver was exchanged. GSH is a very unstable and reactive compd. in the living organism. Felix Saunders

Toxic effects of desoxycorticosterone esters in dogs. Daniel Kuhlmann, Charles Ragan, Joseph W. Ferrebee, Dana W. Atchley and Robert F. Loeb. *Science* **90**, 496–7 (1939).—Dogs on a maintenance diet were injected subcutaneously with 20 mg. of desoxycorticosterone acetate in peanut oil daily for 70 days. There is a striking decrease in serum K, a slight increase in serum Na, serum protein and nonprotein N and no definite change in blood sugar or Ca. All the dogs showed a curious periodic weakness with inability to stand or raise the head. These bouts of paralysis, except for the persistence of reflexes, closely resemble familial periodic paralysis in man, which is also assocd. with marked decrease in serum K. The attacks are alleviated by KCl. Intake and excretion of

water are increased. There is no change in heart contour. There is an increase in arterial pressure. All symptoms disappear 3–4 days after withdrawal of the hormone.
Felix Saunders

Ketone bodies, nonprotein nitrogen, lactic acid, chlorides and carbon dioxide-combining power of the blood of healthy pregnant women. With remarks on the technique of the determination of the blood values. H. Rossenbeck. *Arch. Gynäkol.* **168**, 709–43(1939).—In 10 nonpregnant and 33 pregnant women the normal standards of the blood constituents mentioned in the title were detd. The methods used and described in detail for ketone bodies and nonprotein N were those of Pincussen-Engfeld and Parnas-Wagner, resp. Average figures follow:

Condition	Month of pregnancy	Acetone + diacet acid, mg %	β Hydroxy butyric acid, mg %	Total ketone bodies, mg %	Nonprotein nitrogen mg %	Lactic acid, mg %	Cl, mg. %	CO_2-combining power, vol. %
Nonpregnant	..	1 0	2 2	3 0	32 3	18 9	386.3	49.6
Pregnant	II	2.0	8 6	9.6	32.0	.	398 6	41.2
	III	2 8	7 5	8.6	24.5		416.9	39 0
	IV	1 8	5 1	7.4	23 4	22 8	384 8	43.9
	V	1.4	5 0	5 7	26.7	14 0	383.0	46 8
	VI	1 1	3.8	7 0	24 8	18 9	394.0	48.3
	VII	1 3	5 1	6 8	23 9	20 3	388 1	43.8
	VIII	0 6	3 4	4 8	25 3	20 9	391.0	47.0
	IX	0 8	3.1	4 2	29 2	16 2	393 8	46.2
	X	1 2	3 9	5 1	26.1	19 6	378 9	50.5

As is seen in the table and accompanying charts, the main deviations from normal occur during the 2nd to 4th months of pregnancy, after which time a trend to normal figures is evident.
H. P. G. Seckel

A quantitative study of estrogen-progesterone interaction in the formation of placentomata in the castrated rat. Irving Rothchild, Roland K. Meyer and M. A. Spielman. *Am. J. Physiol.* **128**, 213–24(1940).—Rats were treated with progesterone, or progesterone-estradiol combinations from the 4th to the 8th day of pseudopregnancy inclusive, after being castrated and the uterus traumatized on the 4th day. The injections were given either once or twice daily. The size of the placentomata formed under these conditions varied directly with the progesterone dose and the no. of daily injections. The addn. of estradiol in varying doses to a const. progesterone dose caused increase in the size of the placentomata until an optimal level is reached. Further increase in estradiol level resulted in the formation of smaller placentomata and finally in the complete inhibition of the reaction. Placentomata could be formed in the absence of the pituitary gland, after appropriate progesterone treatment.
E. D. Walter

The identity of the glycotropic (anti-insulin) substance of the anterior pituitary gland. H. Jensen and J. F. Grattan. *Am. J. Physiol.* **128**, 270–5(1940); cf. *C. A.* **33**, 6931⁹.—Adrenotropic anterior pituitary fractions as well as adrenal cortical exts. and cryst. corticosterone acetate produce a definite glycotropic effect. On the other hand, administration of thyrotropic prepns. (free from adrenotropic hormone), prolactin and follicle-stimulating hormone prepns., as well as cryst. thyroxine fail to render the animals (mice) resistant to insulin under the exptl. conditions. The results suggest that the glycotropic effect of the anterior pituitary is produced by the adrenotropic factor.
E. D. Walter

Sucrose-taste thresholds of rats and human subjects. Curt P. Richter and Kathryne H. Campbell. *Am. J. Physiol.* **128**, 291–7(1940); cf. *C. A.* **33**, 5056².—Thirteen rats recognized the difference between distd. H_2O and sucrose soln. in av. concns. of 0.5%. Forty-five young adult human subjects first recognized the difference between distd. H_2O and sucrose soln. in av. concns. of 0.17% and first recognized a sweet taste in av. concns. of 0.41%. Nineteen adults from the lab. staff and clinic patients showed similar results. The sugar-taste threshold of 58 children averaged 0.68% and of 52 elderly individuals 1.23%. Rats and man have nearly the same sucrose-taste thresholds.
E. D. Walter

The mechanism of the inhibiting effect of electrolytes and heparin on blood coagulation. Anthony J. Glazko and David M. Greenberg. *Am. J. Physiol.* **128**, 399–407(1940); cf. *C. A.* **33**, 1804⁷.—A study was made of the inhibiting effect of various electrolytes and of heparin on the 2nd phase of coagulation. The potency of the electrolytes increased with valency, but not as a function of the ionic strength of the soln. The polyvalent anions and heparin inhibit coagulation by acting directly on thrombin. The inhibiting action of multivalent cations was due to their effect on fibrinogen. An explanation of the results is advanced on the basis that alterations of the elec. potentials of thrombin and fibrinogen interfere with the formation of a coagulation enzyme-substrate intermediate.
E. D. Walter

The effect of acid stimulation of the duodenum upon experimental hyperglucemia and utilization of glucose. E. R. Loew, J. S. Gray and A. C. Ivy. *Am. J. Physiol.* **128**, 298–308(1940); cf. *C. A.* **33**, 5518².—With 62 dogs 108 expts. have failed to yield evidence to indicate that acid stimulation of the duodenum enhances the utilization of intravenous glucose or reduces the hyperglucemia produced by absorption of glucose, injection of adrenaline or removal of the pancreas.
E. D. Walter

Acute hypoproteinemia following a single severe hemorrhage in the fasting dog. Robert Elman. *Am. J. Physiol* **128**, 332–7(1940).—The results indicate that there is no rapid mechanism for the restoration of the concn. of serum protein or serum albumin lost by hemorrhage in the fasting dog, and emphasize the importance of inducing such a restoration therapeutically in patients suffering severe blood loss.
E. D. Walter

Calcium in ciliary and muscular movement. G. S. Carter, O. Gatty, J. H. Schulman and H. Walston. *Nature* **144**, 980–1(1939).—The unbalance obtained by reducing the Ca content of physiol. solns. can to some extent be offset by the addn. of small quantities of lipides to the soln. in the case of the beating frog heart and of *Mytilus* cilia. The use of adsorbents and dispersants of protein film and of lipide film suggests that ciliary and muscular cell membranes have some lipide constituents on their outer sides.
E. D. Walter

Connection between carbohydrate and potassium metabolism in normal and adrenalectomized animals. F. Verzár and J. C. Somogyi. *Nature* **144**, 1014–15 (1939).—After adrenalectomy, rats show changes in the behavior of the different sugars in the blood and also disturbances in K metabolism. It is suggested that the connection between these 2 phenomena is due to a phosphorylation process leading to the formation of glycogen or intermediary substances.
E. D. Walter

Hematological studies on cattle. III. Fluctuations in the hemoglobin of Indian Nellore oxen as affected by seasonal variation. Miguel Manresa and Prudencio R. Falcon. *Philippine Agr.* **28**, 187–205(1939); cf. M. Gomez and Santos, *Ibid.* **28**, 79–98.—The av. hemoglobin index of Indian Nellore cattle was 9.79 g. per 100 ml. of blood over a period of 1 year. In both males and females the indexes for the year showed bimodal curves; the first curve is of 7 months duration starting from October and ending in April with the mode in January. Increasing body temp. caused a decreasing hemoglobin index and vice versa. Relative humidity probably does not affect the hemoglobin content. Normal fluctuations in hemoglobin indexes did not affect the percentages of large mono-

nuclears, polymorphonuclears and mast cells. Except for 2 months the percentage of lymphocytes showed trends in the same direction as the hemoglobin but when the hemoglobin was high the content of eosinophiles was low.
Colin W. Whittaker

Changes in the serum protein composition in growing animals. R. I. Golubitskaya. *Méd. exptl.* (Ukraine) **1939**, No. 4, 20-3.—Exptl. acidosis (produced by intravenous injections of isotonic HCl solns.) had no effect on the total protein content or on the proportion of the different protein fractions of the serum of rabbits between the ages of 1 month and 2 years. S. A. Corson

Golgi apparatus and vitamin C. I. Review. Atunobu Miwa. *Oriental J. Diseases Infants* **25**, 38-9(1939)(in English).—Vitamin C probably plays a part in the fixation of Golgi app. by the reduction of $AgNO_3$ and osmic acid. **II. Experimental studies. 1.** *Ibid.* 40.—An aq. soln. of vitamin C, 1 50,000, reduces 10% $AgNO_3$; a vitamin C soln., 1.6000, reduces 10% $AgNO_3$ contg. 1% glacial AcOH. Histochem. pictures showed that the Golgi app. and vitamin C in the tissues of rabbits and hens were closely related. The histochem. pictures of the Golgi app. and vitamin C in the tissues were greatly enlarged after an injection of vitamin C into the portal vein of the living rabbit. Ruth Berggren

Rogers, Charles Gardner: Textbook of Comparative Physiology. 2nd ed. London: McGraw-Hill Publishing Co., Ltd. 715 pp. 30s.

Tuttle, W. W., and Knowlton, G. Clinton: An Introduction to Experimental Human Physiology. London: Henry Kimpton. 138 pp. 7s. 6d.

G—PATHOLOGY.

The nicotinamide content of the blood in diseases of the liver. Its diminution in connection with hepatic insufficiency. Noel Fiessinger, Michel Albeaux-Fernet, André Lwoff and Andriés Quérido. *Bull. mém. soc. méd. hôp. Paris* **55**, 1111 18(1939); cf. *C. A.* **33**, 2928[9], 6372[6], 6128[3].—The blood nicotinamide (I) was normal in infectious benign icterus, compensated cirrhoses and in 1 case of cancer of the liver, but was markedly decreased in 3 cases of severe cirrhotic icterus, one of which had a rapid fatal termination. The urine porphyrin was high in benign icterus, compensated cirrhoses and alc. polyneuritis with a normal I, as well as in decompensated cirrhoses. No const. relation was found between the diminution in I and the increase of porphyrin in the urine. The decrease in I, like the lowering of total and esterified cholesterol in the blood, may be considered a symptom of severe hepatic insufficiency. A spontaneous increase in I permits a favorable prognosis. Ruth Berggren

The nicotinamide content of the blood in pathological conditions. L. Justin-Besançon, A. Lwoff, A. Quérido and J. M. Inbona. *Bull. mém. soc. méd. hôp. Paris* **55**, 1217 24(1939); cf. *C. A.* **33**, 2928[9], 6372[6], 6428[3].—Of 30 patients with various clinical manifestations the blood nicotinamide (I) was below normal in 1 patient with severe icterus during hepatic cirrhosis, in 1 with alc. polyneuritis, in 3 with hemopathies of different etiology and in 2 with scurvy, one of whom also had pulmonary tuberculosis. The uncomplicated scurvy improved after treatment with ascorbic acid and nicotinamide. In the patient with scurvy and tuberculosis the glossitis and aphthous stomatitis disappeared rapidly after the administration of nicotinamide. I was rarely lower than 0.40 mg. %.
Ruth Berggren

The role of the pituitary gland in water balance. Peter Heinbecker and Harvey L. White. *Ann. Surg.* **110**, 1037-49(1939).—Diabetes insipidus results only after functional or anatomic removal of all the neural hypophysis. The anterior lobe normally probably plays a diuretic role. Creatinine clearance is unchanged and urea clearance somewhat elevated during the transitory phase of exptl. diabetes insipidus. Rachel Brown

The control of water and electrolyte balance in surgical patients. J. Russell Elkinton, Monroe T. Gilmour and Wm. A. Wolff. *Ann. Surg.* **110**, 1050-66(1939).—Electrolyte and water balance in surgical patients can be evaluated fairly accurately by simultaneous detns. of hematocrit value, plasma protein, chlorides and CO_2-combining power. From the 2 latter figures the total base is approximated. Hemoconcn., as shown by a rising hematocrit or plasma protein value, is an indication of serious depletion of the extracellular water. A falling total base concn. indicates serious extracellular base depletion, and, when corrected for hemoconcn., can be used to calc. the amt. of base required. The analytic results also indicate the type of parenteral fluid needed, either whole blood, plasma, physiol. saline, bicarbonate and lactate, or glucose in distd. H_2O. Rachel Brown

Changes in blood chemistry after burning injuries and in other grave surgical conditions; with some references to treatment by desoxycorticosterone acetate. W. C. Wilson and C. P. Stewart. *Edinburgh Med. J.* **46**, *Trans. Med.-Chir. Soc. Edinburgh* **118**, 153-73(1938-39).—After burns serum Na and chlorides fall, while serum K, nonprotein N and urea N and blood chlorides, nonprotein N and urea N rise. There is usually an increased corpuscular concn. Na is lost from other extracellular fluids as well as from blood serum. Evidence indicates that it is lost into the damaged tissues. Some Na passes from serum into red blood cells. The circulatory failure of secondary shock in burns is not due primarily to a low level of serum Na or to any other blood change. Desoxycorticosterone acetate (I) rapidly restores the normal Na level of extracellular fluids and corrects the other blood abnormalities. I also has an occasional effect in improving circulatory efficiency during secondary shock and acute toxemia of burns. In other surgical conditions assocd. with grave circulatory disturbance I has an occasional beneficial action on circulatory failure. It has no obvious effect in bacterial infections. I was administered in oil soln. Rachel Brown

Cancer and its biochemical factors. Maurice Copisarow. *Edinburgh Med. J.* **46**, 781-807(1939).—A review with 287 references. Rachel Brown

A chemical study of ketosis in a dairy herd. C. W. Duncan, C. F. Huffman and H. A. Tobin. *J. Am. Vet. Med. Assoc.* **95**, 690-700(1939).—In 9 Jersey cows suffering from acetonemia the ketone bodies in the blood varied from 1.55 to 79.05 mg. per 100 cc. (mean 23.09 mg.) and the variation in the urinary ketone bodies was 20.3 to 549.5 mg. (mean 154.5 mg.). Four weeks after treatment by a changed diet and administration of chloral hydrate ketone bodies in the blood had decreased to 2.96 and in the urine to 53.6 mg. Ketone bodies in the milk varied from traces to 42.9 mg. No disturbance was indicated in plasma Ca, Mg and Cl. Acidosis was not encountered. There was no relationship between the blood ketone bodies and the CO_2-combining capacity of the blood. The qual. Na nitroprusside test could not be correlated with the amt. of ketone bodies detd. in the urine. 37 references. Rachel Brown

Serum protein changes in different types of cattle during immunization against rinderpest virus. M. H. French. *J. Comp. Path. Therap.* **52**, 183-91(1939); cf. *C. A.* **33**, 3867[8].—Immunization of cattle against rinderpest is attended by changes in the serum protein fractions which are not dependent on breed. There is an increase in globulin, chiefly euglobulin, and a decrease in albumin proportions. The time taken to develop the max. euglobulin content appears shorter with zebu than with other types of cattle examd., but the max. value is of the same order for each type. Rachel Brown

The cerebrospinal fluid in the bovine: its composition and properties in health and disease with special reference to turning sickness. J. Carmichael and E. R. Jones. *J. Comp. Path. Therap.* **52**, 222-8(1939).—Thirty-three bovine spinal fluids gave the following av. values: 10.6 leucocytes per cu. mm., 34.3 mg. total protein per 100 cc., 36.8 mg. glucose, 685.1 mg. chlorides as NaCl, 16.1 mg. nonprotein N, 10.8 mg. urea N, 1.4 mg. creatinine and 5.5 mg. Ca per 100 cc. The Lange colloidal Au test was neg. In 15 cases of turning sickness increases were noted in cell count, globulin and total protein and in one there was a

pos. Lange reaction. Five specimens taken from rinderpest, trypanosomiasis and East Coast fever showed little abnormality. Rachel Brown

The role of endocrine glands in the pathogenesis of allergic reactions. II. Arthus' phenomenon in rabbits thyroidectomized at the peak of sensitization. G. S. Voronyanskiĭ. *Méd. exptl.* (Ukraine) **1939**, No. 4, 7–13. —Fifteen male rabbits were sensitized by 6 injections of 2-cc. doses of normal horse serum into the marginal ear vein at 5-day intervals. Total thyroidectomy performed during the interval between the last sensitizing dose and the toxic dose led to mitigation of Arthus' phenomenon but could not completely prevent its development. S. A. Corson

Physicochemical indexes of the allergic state in animals of different ages. G. Miroshnik. *Méd. exptl.* (Ukraine) **1939**, No. 4, 14–19.—Rabbits and guinea pigs were sensitized by horse serum injections. During the sensitization stage the animals showed no significant changes in the pH (Mislowitzer's method, cf. *C. A.* **21**, 431), buffer capacity and Ca content (de Waard method, cf. *C. A.* **14**, 1559) of the blood serum. During the anaphylactic shock there was a decrease in blood pH and in most cases also in the serum Ca. Guinea pigs can be easily sensitized irrespective of age, while in rabbits the strongest reaction was obtained at the age of 3 months, the most feeble reaction—at the age of 1 month. S. A. Corson

A serological reaction in tuberculosis. John B. West and Ruth M. Easterling. *Am. Rev. Tubercl.* **40**, 599–603 (1939).—In 1930 Hinton (*C. A.* **24**, 2800) proposed a cholesterol agglutination reaction. Bacilli of 3 strains were extd. with 4 portions of ether (Squibb) and the residue was dried at room temp. The ether-insol. residue was then extd. with 5 vols. of 95% EtOH by wt. For serological tests a mixt. of 9 parts of 0.6% soln. of cholesterol in abs. alc. was added to 1 part of bacterial antigen. Liver (from miliary tuberculosis) antigen was likewise prepd. Serums were inactivated at 55° for 15 min. and used in 0.1-cc., 0.3-cc. and 0.5-cc. amts., and to each was added the "glycerinated indicator" prepd. according to Hinton's outline. The tubes contg. the mixt. were shaken for 3 min. at 250 oscillations per min. and then incubated at 37.5° for 16 hrs. and then read, like the Hinton glycerol-cholesterol reaction for syphilis. Of 161 serological tests on cases diagnosed as active tuberculosis clinically, by x-ray, by sputum or by some combination of all 3, all were pos. except 3. Of 18 inactive tuberculosis 4 gave pos. reactions, and the remainder neg. Of 328 control serums only 2 were pos. The work is being continued. H. J. Corper

The effect of tuberculous infection on the carbonic anhydrase of rabbit blood. Cecilia Shiskin. *Tubercle* **20**, 227–38(1939).—The carbonic anhydrase of 17 normal rabbits (41 estns.) varied from 1.18 *E* to 2.26 *E* with an average of 1.56 *E* per cu. mm. of whole blood, and from 2.92 *E* to 6.4 *E* with an average of 4.2 *E*. per cu. mm. of red corpuscles (Meldrum and Roughton (*C. A.* **28**, 2734[3]) have assigned the value *E* to that amt. of enzyme which, when dissolved in 4 cc. of the phosphate-bicarbonate mixt. (equal vols. of 0.2 *M* Na_2HPO_4 and 0.2 *M* KH_2PO_4 and a soln. of $NaHCO_3$ made by dissolving 0.2 *M* $NaHCO_3$ in 0.02 *M* NaOH, prepd. fresh every 4 days), gives a value $(R - Ro/Ro)$ equal to unity at 15°C., if *R* is the rate of evolution of CO_2 during the second quarter of the process (as given by the reciprocal of the time taken) in the presence of catalyst, and *Ro* the rate in the absence of the catalyst, then $(R - Ro/Ro)$ is a suitable measure of catalytic activity). No significant difference was observed between the male and female rabbits. In rabbits infected with tuberculosis, while the av. value remained unchanged both in whole blood and corpuscles (1.50 *E* and 4.18 *E*), much lower values were observed in individual rabbits. In 3 of these rabbits *in extremis*, samples of blood showed a reduction in carbonic anhydrase to $1/2$ or even $1/3$ of the value obtained a few days previously. This marked fall in the carbonic anhydrase could not be ascribed to the reduction in red cells. It would appear that this decrease might be attributed to the action of the enzyme of a toxin, which is not necessarily specific to tuberculosis. In the healthy rabbit the carbonic anhydrase appeared to be more than sufficient for normal requirements and the animal was even capable of maintaining this when infected with tuberculosis. When it became acutely ill toward the end of the disease, however, there was in some cases a striking reduction in the enzyme. H. J. Corper

Proposal for a standard method for the preparation of tuberculin and of an anti-tuberculosis vaccine. G. Petragnani. *Tubercle* **20**, 314–20(1939).—In 1926 Petragnani published a paper on the prepn. of a tuberculin (anatuberculin) (*Atti accad. fisiocritici. Siena*). He uses 10 strains each of virulent human and bovine tubercle bacilli and some avian strains, cultured in liquid synthetic medium (Sauton's). In the first month the neutral reaction changes progressively toward the alk. side until pH 9 is reached, when a gradual lowering to a marked acid reaction sets in (pH 4), which indicates the exhaustion of the medium and the maturation of its antigenic properties in the 2nd month. After the addn. of an equal vol. of sterile water, 7 cc. of formalin at 40 vol. per l. are added, followed by further incubation for 20 days. Ten cultures of human and bovine strains and one avian are filtered through a sterile gauze and cotton filter. The culture liquid is adjusted at pH 7.2 and is again incubated for 10 days. The liquid is anatuberculin. The bacillary bodies pressed out and weighed are triturated in a large mortar with a 3-fold quantity (wt.) of pure sterile NaCl and used to prep. integral anatuberculin, which consists of adding 1 cc. of normal NaCl with formalin to a homogenous emulsion of tubercle bacilli. This must never be exposed to a temp. above 37–38°. Three parts of NaCl are added to the moist bacilli in a sterile porcelain or glass mortar with grinding and the slow addn. of water and 6% formalin (at 40 vols.) till a concn. of 1.8% NaCl and 0.6% of bacillary bodies is reached. The mixt. is kept for 4 to 8 wks. in the incubator and an equal quantity of slightly alk. water is added. This is integral anatuberculin. This injected in doses of 0.1, 0.2 or 0.5 cc. into animals and children causes a nodule after several weeks which becomes a cold abscess and may rupture. This antituberculosis vaccine produces a marked sp. allergy for tuberculin and increases the resistance to infection in man and animals. Twelve Italian references to the original observations are appended. H. J. Corper

Acute or chronic tuberculous lesions produced by colonial variants of tubercle bacilli. K. C. Smithburn. *Tubercle* **20**, 420–5(1939).—Four lines of cultures derived from a single strain of bovine tubercle bacilli by cultivation at different pH values showed marked differences in colony morphology which were used in tests of their pathogenic properties. Cultivation at pH 6.0 yielded colonies which were coarsely granular and markedly attenuated. Lesions produced by these organisms were of the "hard" tubercle type, were non-invasive, and showed little tendency toward caseation. A pH of 6.8 proved to be the optimum for the cultivation of smooth colonies which were highly virulent. These organisms produced "acute" or "soft" tubercles which were invasive and showed a marked tendency to caseation. Cultivation of the organism at pH 6.4 through several generations yielded granular colonies which were moderately attenuated. Cultivation at pH 7.2 yielded finely granular, flat colonies which were slightly attenuated. Lesions produced by the latter two lines of cultures were of both the "acute" and "chronic" type, the cultures grown at pH 7.2 inducing the formation of the greater no. of "acute" lesions. H. J. Corper

Influence of experimental nephritis, hepatitis or hepatonephritis from various causes on the various nitrogenous constituents of blood serum of dogs. E. Aubertin and R. Martinet. *Compt. rend. soc. biol.* **132**, 264–7(1939).—Nephritis, hepatitis, or both were produced in dogs by poisoning with CCl_4, P in oil, or U nitrate, or by resection of the bile duct, or by intravenous injection of horse hemoglobin. Increases in most of the N compds., except albumin and sometimes creatine, were found (no analytical data given). L. E. Gilson

[Inhibiting] action of diethyl ether on histamine release in anaphylaxis. G. Katz, C. T. Frey and L. Ireland Frey.

Proc. Soc. Exptl. Biol. Med. **42**, 716–18(1939).—Preliminary. L. E. Gilson 1

Cystinuria in two Scotch terriers. Edwin R. Blamey and Erwin Brand. *Proc. Soc. Exptl. Biol. Med.* **42**, 747–9 (1939).—The urine contained 200–400 mg. cystine per l. Some calculi formed in one dog. L. E. Gilson

Influence of sex and age on the diabetic traits in a strain of rats. Versa V. Cole and Ben K. Harned. *Proc. Soc. Exptl. Biol. Med.* **42**, 758–61(1939); cf. *C. A.* **32**, 8551[7], 8596[1].—Females of the Yale strain exhibit a low glucose tolerance similar to that of the males. The estrus cycle is not a factor. After 240 days of age the severity of the diabetic trait increases in the males. L. E. Gilson 2

Macromolecular [protein] component of chick embryo tissue diseased with western-strain encephalomyelitis virus. D. G. Sharp, A. R. Taylor, Dorothy Beard, Harold Finkelstein and J. W. Beard. *Proc. Soc. Exptl. Biol. Med.* **42**, 790-2(1939); cf. *C. A.* **34**, 781[8], 808[9].—Preliminary report on ultracentrifugation expts. L. E. G. 3

Hyaluronic acid in pleura fluid associated with malignant tumor involving pleura and peritoneum. Karl Meyer and Eleanor Chaffee. *Proc. Soc. Exptl. Biol. Med.* **42**, 797-800(1939).—Hyaluronic acid (cf. *C. A.* **32**, 7937[2]) was present to the extent of 0.14–0.18% in the chest fluid of a patient with a malignant tumor. L. E. Gilson

Immunological studies on the cellular constituents of C. diphtheriae. Sam C. Wong and T. T'ung. *Proc. Soc. Exptl. Biol. Med.* **42**, 824–8(1939).—A method for the isolation of a type-specific protein from *C. diphtheriae* is described. Both the lipoid and carbohydrate fractions are group-specific while the alkali-sol. protein is type-specific. The type-specific substance is heat-labile and is converted into a group-specific protein by heating 30 min. at 56°. 4
L. E. Gilson.

Hypoglucemia and increased insulin sensitivity following hypothalamic lesions [in dogs]. Allen D. Keller. *Proc. Soc. Exptl. Biol. Med.* **42**, 837–8(1939).—Preliminary. L. E. Gilson

Biochemistry of insulin shock. II. Chlorides in the tissues. Filippo Romeo. *Arch. farmacol. sper.* **68**, 99-104(1939); cf. *C. A.* **34**, 155[2]. Rabbits were killed by insulin shock. Cl diminished in practically all the organs except the nervous tissue, where it increased. Helen Lee Gruehl

Ascorbic acid content of the organs in experimental infection with influenza virus. F. De Ritis and G. Stolfi. *Boll. soc. ital. biol. sper.* **14**, 634-5(1939).—In the rat there were no appreciable alterations in ascorbic acid content of the organs after infection. Helen Lee Gruehl

Histaminemia and histaminolysis in Quincke's edema. L. Businco. *Boll. soc. ital. biol. sper.* **14**, 646-8(1939).—At the end of an attack the histamine titer and histaminolytic power of the blood increased markedly. In the same person during normal periods the histamine titer diminished to values still somewhat above normal. H. L. G. 7

Experimental rickets from the administration of beryllium carbonate. L. Businco. *Boll. soc. ital. biol. sper.* **14**, 649–51(1939). Helen Lee Gruehl

Chemical constitution of ovarian cyst fluid. G. Stolfi. *Boll. soc. ital. biol. sper.* **14**, 657–9(1939).—In comparative tests with blood, the cyst fluid contained about the same amt. of N, more NaCl and less protein. The P and glucose values varied greatly. Helen Lee Gruehl 8

Various fractions of residual nitrogen of the blood during traumatic shock. G. Stolfi and L. Provenzale. *Boll. soc. ital. biol. sper.* **14**, 661-2(1939).—In rabbits traumatic shock caused an increase in urea and creatinine but did not alter the creatine, amino acid or uric acid N of the blood. Helen Lee Gruehl

Hemoglobin and porphyrin metabolism in various anemic conditions, particularly pernicious anemia. L. Cotti. *Boll. soc. ital. biol. sper.* **14**, 710–12(1939).—In hemolytic icterus and pernicious anemia there was an increase in porphyrin excretion independent of the amt. of hemolysis. Fecal porphyrin excretion increased in hypochromic anemia. Helen Lee Gruehl 9

Sugar metabolism and insulin therapy in acne vulgaris. H. C. Semon and F. Herrmann. *Roy. Soc. Med., Sect. Dermatol.* **1939**; *Brit. J. Dermatol. Syphilis* **51**, 477–81 (1939).—Ten men and women with acne showed glucose-tolerance curves characterized by a lag in return to the initial fasting blood-sugar level. This lag was especially marked in women during the premenstrual and menstrual periods, when the acne was exacerbated. Improvement in the skin condition uniformly followed administration of 5–10 units insulin, generally twice weekly. M. Horn

Arteriosclerosis. Ludwig Aschoff. *Z. ges. Neurol. Psychiat.* **167**, 214–37(1939).—A review, with an extensive bibliography, emphasizing the chem. factors (Ca, lipoids, vitamins, hormones) in the pathogenesis of arteriosclerosis. Marion Horn

Arteriosclerosis. W. Frey. *Z. ges. Neurol. Psychiat.* **167**, 237-73(1939).—A review, with an extensive bibliography, of the diagnosis, incidence, pathogenesis, prevention and treatment of arteriosclerosis. Marion Horn

The carcinolytic power of serum in certain diseases of the visceral organs. N. E. Kavetskiĭ. *J. méd., Ukraine* **9**, 61-5(in French 65)(1939).—The carcinolytic power of the serum falls sharply in visceral cancer, and also to a lesser extent in those diseases of a precancerous state, such as chronic gastritis, with diminution of gastric juice, gastric ulcers, etc., which show an inhibition of the active mesenchyme. A sharp fall in the carcinolytic power of the serum is also noted in pneumonia. S. A. Karjala

The carcinolytic power of the blood serum and of extracts of organs of rats resistant to Jensen's sarcoma. S. R. Muchnik and M. Vurgaft. *J. méd., Ukraine* **9**, 67–72 (in French 72)(1939).—The blood serum and exts. of the liver and kidneys of rats resistant to Jensen's sarcoma have a higher carcinolytic power than those of normal rats and of rats with tumors. S. A. Karjala

Blood glutathione in certain internal diseases. G. L. Vitkovskaya. *Klin. Med.* (U. S. S. R.) **16**, 991–5(1938). —The normal content of reduced glutathione (I) in the venous blood of healthy persons is 21–30 mg. %. No changes in I were observed in cases of heart disease without acute symptoms and in rheumatic polyarthritis. Patients with diseases of the endocrine system show a decrease in reduced I while hyperthyroidism is characterized by an increase in reduced I. S. A. Karjala 5

The glutathione content of the blood of leucemic patients. K. M. Malenkova. *Klin. Med.* (U. S. S. R.) **16**, 1007-9(1938).—Leucemic patients have a higher content of total glutathione (I) than normal subjects while the ratio of oxidized I to reduced I is below normal. The I content of erythrocytes differs only slightly from normal, most of the increased I being found in the leucocytes. S. A. Karjala 6

Changes in the oxidation-reduction potential [of the blood] in cardiovascular diseases and pneumonia. A. D. Bogdanova. *Klin. Med.* (U. S. S. R.) **16**, 1372–7(1938).—The oxidation-reduction potential (I) of the blood of patients with insufficient blood circulation is decreased, but in cases of compensative disorders no changes are observed. At the crisis in pneumonia a reduction in I occurs, with a rise to normal during convalescence. I is an unsatisfactory diagnostic measure in these cases. S. A. Karjala

Carotene in the blood and its pathological significance. Ya. S. Khentov, F. A. Rachevskiĭ and A. M. Shendel. *Klin. Med.* (U. S. S. R.) **17**, No. 8, 20–5(1939).—The carotene (I) content of the blood lies within the limits of 0.02–0.05 mg. % in normal subjects, and in patients with cancer of the stomach, cholecystitis, stomach ulcers, etc., while in patients with bronchial asthma, tuberculosis or cancer of the lungs, diabetes, pernicious anemia, hypertonia, arterial sclerosis, cirrhosis of the liver, severe hepatitis, etc., it increases to 0.06–0.2 mg. %. Carotenemia is due to a reduction in the oxidative processes of the organism as a result of destroyed liver function. Thyroidin, prolan, insulin and raw liver increase the oxidative processes and liver function and decrease the amt. of I in the blood. S. A. Karjala 10

Iron metabolism in anemic conditions. II. The determination of the iron balance after iron treatment. L. A. Brodovich. *Klin. Med.* (U. S. S. R.) **17**, No. 8, 69–74 (1939); cf. *C. A.* **33**, 8776[3].—The administration of 1 g.

of Fe lactate often results in considerable retention of Fe in both healthy persons and anemic patients. There is no greater tendency for retention of Fe in cases of hypochromic anemia than in normal subjects. S. A. Karjala 1

Species specificity of proteins from the optic lens. Leo Markin and Preston Kyes. *J. Infectious Diseases* **65**, 156-9(1939).—The lack of agreement on the species specificity of lens protein among workers using anaphylaxis as the immune reaction for comparisop of species may be due to, among other factors, the use of too small groups of animals. The authors, experienced in the use of pigeons and convinced of their superiority for anaphylaxis, repeated the usual expts. with a large group of these animals and concluded that the constituent proteins of the lens are the same in mammalian species as widely sepd. as dog and beef. Autosensitization to lens protein, though produced in guinea pigs, could not be produced in pigeons. 2
Julian H. Lewis

The value of the complement-fixation test in the diagnosis of psittacosis. K. F. Meyer and B. Eddie. *J. Infectious Diseases* **65**, 225-33(1939); cf. *C. A.* **33**, 8283[9].—The complement-fixation tests with cocto-antigens prepd. from virulent mouse spleens or preferably Rivers-Li tissue cultures of the virus are invaluable aids in the early and late diagnosis of human psittacosis. Convalescent human serum and immune goat serum may shorten the course of the disease. 3
Julian H. Lewis

The pallida reaction. H. Gärtner. *Z. Immunitäts.* **96**, 225-35(1939).—Experience with the pallida reaction for syphilis in which an ext. of spirochetes is used as antigen indicates that the method is of chief value as a connecting link between the Wassermann reaction and the flocculation reactions. Certain precautions in the technique of the reaction are described. 4
Julian H. Lewis

Apparent deviations of the Kauffmann-White scheme in the use of immune serums obtained with isolated O antigen. Richard Haas. *Z. Immunitäts.* **96**, 275-86(1939). In spite of the practical significance of the Kaufmann-White scheme of antigens of the typhoid-paratyphoid-enteritis bacilli no investigations have been made on the application of the scheme to dissolved constituents of the organisms. Rabbits immunized with endotoxin solns. of paratyphoid B or D made by extg. the bacilli with trichloroacetic acid produce antiserums that react with these solns. The antiserums show cross reactions between paratyphoid B and D which are attributed to the presence in both of antigen XII. By absorption with heterologous strains antiserums are obtained which according to the Kaufmann-White scheme are specific for antigen *O*. Typhoid endotoxin antiserums neutralize paratyphoid B endotoxin and vice versa. This effect is due to the presence of the XII—*O* antigen. 5
Julian H. Lewis

The serological diagnosis of Weil's disease. W. Gaehtgens. *Z. Immunitäts.* **96**, 287-319(1939); cf. *C. A.* **28**, 5122[6].—The large increase of cases of Weil's disease demands certain and ready means of diagnosis. The isolation of the causative organisms comes first in importance, then the serological tests, agglutination or complement fixation, with *Spirochaeta icterogenes* as antigens. Both serological methods give good diagnostic results, but each has advantages over the other. 6
Julian H. Lewis

Antibody formation for mucin. K. L. Freiherr v. Godin. *Z. Immunitäts.* **96**, 320-6(1939).—Mucin as such cannot form precipitins. The precipitins formed by injecting the best purified mucin are due to the rest protein that remains as a contaminant. Since the contaminating protein cannot be removed the inactivity of mucin was detd. by indirect evidence which involved quant. serological tests that accounted for the contaminating protein. 7
J. H. L.

The biological action of the acetylpolysaccharide from human tubercle bacilli. Yosiharu Takeda, Tatuo Ota and Minoru Sato. *Z. Immunitäts.* **96**, 326-34(1939).—Acetylpolysaccharide isolated from the aq. ext. of defatted human tubercle bacilli produced immune precipitins. It also reacted with 82% of the serums from tuberculous patients and 54% of the serums from lepers. It did not react with human serum from patients with no pulmonary tuberculosis. In tuberculous guinea pigs it gave a diffuse reddish skin reaction with hemorrhage or necrosis. 8
J. H. L.

The influence of the thyroid hormone on anaphylactic shock in guinea pigs. H. W. Stietzel. *Z. Immunitäts.* **96**, 352-60(1939).—Thyroid hormone inhibits anaphylactic shock instead of increasing it as formerly believed. The degree of inhibition corresponds to that produced by ascorbic acid. The intraperitoneal injection of a thyroid prepn. increases the globulin fraction of guinea-pig serum. 9
Julian H. Lewis

The production of active immunity by cutaneous application of ointments. R. Torikata and S. Ozu. *Z. Immunitäts.* **96**, 413-26(1939).—Cocto-antigen applied to the skin in the form of an ointment for 24 hrs. produces a higher titer of antibodies but more slowly than does the same amt. of antigen given intravenously. Cocaine added to the ointment decreases antibody production. An irritant added has no effect on the amt. of antibody formation but lowers the rate. 10
Julian H. Lewis

The isolation of a glucose-containing cerebroside from spleen in a case of Gaucher's disease. Nellie Halliday, Harry J. Deuel, Jr., L. J. Tragerman and W. E. Ward. *J. Biol. Chem.* **132**, 171-80(1940).—The cerebroside sepd. from the spleen of a patient suffering from Gaucher's disease resembled kerasin except that it contained glucose rather than galactose. In all probability this glucose-contg. cerebroside is the result of an anomaly in carbohydrate metabolism rather than the characteristic of the disease. It is suggested that the term "glycolipide" be reserved for those cerebrosides having glucose as the component carbohydrate while "galactolipide" be used to describe those contg. the galactose mol. 11
A. P. L.

Properties of the inhibitor associated with the active agent of chicken tumor I. Albert Claude. *Am. J. Cancer* **37**, 59-63(1939); cf. *C. A.* **32**, 5491[8].—The inhibiting factor found in exts. of slowly growing chicken tumor I appears to be a protein. 12
E. R. Main

Antistreptolysin S titers in rheumatic fever. E. W. Todd, Alvin F. Coburn and A. Bradford Hill. *Lancet* **1939, II**, 1213-17; cf. *C. A.* **33**, 1034[3]. The titer of antistreptolysin S in the serum of children with active rheumatic fever tends to be lower than in the serum of nonrheumatic children or rheumatic children during periods of rheumatic inactivity. The titer is lowest when the symptoms are the most pronounced. The antistreptolysin O titer tends to become increased during active rheumatic fever. 13
E. R. Main

Spectroanalytical investigations on the magnesium content of blood with various diseases. Elizabeth Zimmer. *Spectrochim. Acta* **1**, 93-106(1939).—The general physiol. and pharmacol. properties of Mg are reviewed. Chem. detns. are restricted to micromethods. Details concerning app. and procedure are given for spectrochem. detns. of Mg in blood. The light source is an interrupted arc between Cu electrodes with 0.03 cc. blood mixed with 0.06 cc. of 0.9% NaCl soln. dried on the anode and a small amt. of AuCl soln. added to supply an internal standard. Parallel detns. of Mg in natural and in ashed blood samples showed that albumin in the former appears to enhance the Mg line. Mg values obtained with unashed blood were reduced by 53% to correct for this effect. Relative values of Mg in blood of 67 patients with various diseases range from 3.4 to 5.7 mg. per 100 cc. The av. error is ± 13%. Correlation of the Mg content of blood with particular diseases could not be established. 14
W. F. Meggers

Observations on human beings with cancer, maintained at reduced temperatures of 75°-90° Fahrenheit. Lawrence W. Smith and Temple Fay. *Am. J. Clin. Path.* **10**, 1-11(1940).—Exposures of 4-5 days at these temps. repeated 3 times caused a drop in blood urea, nonprotein N and chlorides with no other definite changes in blood chemistry. The urinalysis is unchanged. The basal metabolic rate is reduced, but direct calorimetry should give less erratic results. 15
John T. Myers

Histologic structure of carcinomas of the stomach and quality of gastric secretion. Alexander Brunschwig and T. Howard Clarke. *Ann. Internal Med.* **13**, 1001-4

(1939).—There was no correlation between the type of carcinoma and the character of gastric secretion. John T. Myers

Tissue metabolism and phosphatase activity in early callus. J. P. Tollman, D. H. Drummond, A. R. McIntyre and J. Dewey Bisgard. *Arch. Surg.* 40, 43–53 (1940).—The levels of phosphatase and of Ca in infected fractures in rabbits were lower than in sterile fractures. There was a uniform rise in the level of blood phosphatase in the infected series. In both infected and sterile fractures, high levels of phosphatase activity were assocd. with the presence of large Ca deposits. J. T. M.

Experimental goiter due to calcium. C. Alexander Hellwig. *Arch. Surg.* 40, 98–102(1940).—$CaCO_3$ is as effective in producing goiter in white rats as is $CaCl_2$. Addn. of vitamins to a goitrogenic diet did not prevent hyperplasia of the thyroid. Prolonged feeding of the goitrogenic diet did not produce secondary thyroid atrophy. A diet rich in Ca and low in I produced parenchymatous goiter. A diet rich in Ca and relatively rich in I produced colloid goiter. The amt. of I required to prevent goiter is variable and depends on the presence and intensity of pos. goitrogenic agents. John T. Myers

Etiology of stone in the common bile duct. R. Franklin Carter, Carl H. Greene, J. Russel Twiss and Richard Hotz. *Arch. Surg.* 40, 103–19(1940).—When the gall bladder becomes functionless, the common duct takes over the function of concg. the bile. Concn. in the duct may be increased by stasis and by gastric achylia which predisposes to infection. These factors favor the deposition of bile sand and the formation of Ca bilirubinate stones. John T. Myers

Immunological experiments with highly concentrated suspensions of the Rous I tumor-producing agent. C. R. Amies and J. G. Carr. *J. Path. Bact.* 49, 496–513(1939). —The tumor agent has at least 2 antigenic components, corresponding to 2 antibodies. One of the antibodies is present in Rous immune fowl serum and the other in anti-fowl rabbit serum. Concd. suspensions were obtained by sedimenting the agent from cell-free tumor exts. by means of centrifuging at pH 5.0–5.5 and digesting the resuspended deposit with com. trypsin at pH 9.0, the process being repeated several times. John T. Myers

Fluorine with relation to teeth. C. G. Gillespie. *Calif. State Dept. Health Weekly Bull.* 18, 145–6(1939).—F can be removed from water by filtration through pure tricalcium phosphate, by freezing the water and eliminating the core in which F is concd., and by distn. It is stated that F values reported earlier than 5 yrs. ago should be discarded because no account was taken of interfering substances. J. Pinchack

The pancreatic enzymes and food allergy. Anton W. Oelgoetz, Paul A. Oelgoetz and J. Wittekind. *Med. Record* 151, 276–9(1939).—The hypothesis that food allergy is caused by diminished duodenal pancreatic enzymes is supported by demonstration of such enzymes in organs and tissues, data for the liver being given. A test for pancreatic enzymes in blood serum is described, which involves the use of starch suspension plus Lugol soln. J. Pinchack

Sensitization to simple chemicals. V. Comparison between reactions to commercial and to purified dyes. Rudolph Hecht, Ludwig Schwarzschild and Marion B. Sulzberger. *N. Y. State J. Med.* 39, 2170–3(1939); cf. *C. A.* 32, 2601[9].—On the basis of patch tests with com. and chemically purified tetrabromofluoresceins in 8 hypersensitive patients, it is suggested that not the dye itself but some impurity or by-product of manuf. may be responsible for allergic reactions or may act synergistically with the dye to produce such reactions. J. Pinchack

Preliminary note on the production of cirrhotic changes in the liver by furfural feeding. Waro Nakahara and Kazuo Mori. *Proc. Imp. Acad.* (Tokyo) 15, 278–81 (1939)(in English).—Of the known constituents of saké, including carbohydrates, amines, MeOH, EtOH, EtMeCO, C_3H_4O and furfural, etc., only furfural produced any pathol. changes in expts. on 700 rats over a period of 300 days. Forty cc. furfural was mixed with 1 kg. polished rice and over a period of 2 months the dose was increased to 100 cc./kg. Sixty-two rats fed on this rice died during the first 37 days and showed no liver symptoms. The rest of the rats all showed symptoms ranging from somewhat localized whitish areas to generalized cirrhotic changes. The longest survival time was 88 days. M. Schubert

The influence of rice-bran oil on the growth and histology of normal and tumorous tissues in tissue culture. Syuzo Morigami. *Gann* 33, 384–9(1939).—Okada (*Osaka Igaku Zasshi* 37, 827(1938); cf. *C. A.* 34, 1804) reported that daily ingestion of a small amt. of rice-bran oil prevented the production of cancer in livers of dimethylaminoazobenzene-fed rats. In the present study the action of various fractions of rice-bran oil was tested upon the outgrowth of normal and tumorous tissues *in vitro*. Rice-bran oil (R) was sapond. with alc. KOH and the unsaponifiable material was extd. with ether. The ether-sol. material was divided into acetone-sol. fraction (L) and acetone-insol. fraction (U). The fraction U was treated with CH_3OH and 3 different cryst. substances, U_1 and U_2 and U_3, have been isolated. All the fractions were tested in concn. of 0.05% in the culture medium of normal chicken embryo fibroblasts and tissue of rat sarcoma due to benzopyrene. The results showed that fraction R stimulated the growth of normal fibroblasts. Fraction L significantly stimulated the growth of both normal and sarcomatous tissues. Fraction U had definite inhibitory action upon both normal and sarcomatous tissues. Fractions U_1 and U_2 more or less stimulated the growth of fibroblasts, but U_3 inhibited the growth markedly. K. Sugiura

Serological study on the specific type substance in the saliva and salivary glands of man. I. Saliva. Eisyoku Kin. *J. Chosen Med. Assoc.* 29, 1988–2024(German abstr., 128–9)(1939).—The specific type substances present in the saliva of type A and type B groups are heat-stable (100°C. for 20 min.), and are not sol. in alc. or Et_2O. *Anti-A* or *-B* serum (immunized against saliva of type A or B), does not give specific pptn. reaction with the saline ext. of salivary glands or lipides of the glands. S. Tashiro

CARL F. SCHMIDT

An investigation on the alleged toxicity of cod-liver oil for pigs. N. J. Scorgie and Wm. C. Miller. *Empire J. Expl. Agr.* 7, 357–68(1939).—Genuine cod-liver oil is not a factor in the causation of toxic liver dystrophy of pigs, even when given in excessive amts. J. R. Adams

Phosphotungstic tuberculin. Yosio Miyazima. *Oriental J. Diseases Infants* 24, 30–1(1938)(in English).—Human and bovine types of tubercle bacilli were cultured on an albumose-free medium for 8 weeks. The phosphotungstic tuberculin (I) was prepd. from the filtrate of this culture by the method of Boquet and Sandor (*C. A.* 31, 6688[7]). The intracutaneous reaction of I in tuberculous guinea pigs was the same as that of the old-style tuberculin (II) for the human type but somewhat stronger than that of II for the bovine type. I was less toxic than II, the min. lethal dose of I being 1.0 cc. Subcutaneous injection of I produced an increase in the body temp. of the tuberculous guinea pig. Both I and II gave pos. reactions in the tuberculous guinea pig after the same time interval. I showed a marked resistance to ultraviolet light. Treatment of I with pepsin or trypsin for 12 hrs. caused rapid soln. and destruction of the active material. Animal charcoal adsorbed the active material of I in 3 hrs. Ruth Berggren

The oxidation-reduction potentials of living tissues. III. The influence of intravenous injections of adrenaline,

histamine, potassium cyanide and vitamin C on the oxidation-reduction potentials in the living rabbit. Tatuo Araki. *Oriental J. Diseases Infants* 25, 33–5(1939) (in German).—An injection of 0.05, 0.1, 0.2 or 0.5 mg. adrenaline per kg. body wt. decreased the oxidation-reduction potentials (o-r p.'s) of the liver and muscle, as estd. by A.'s method (*Ibid.* 22, 29(1937)) and somewhat later increased that of the spleen. These results are attributed to the circulatory changes produced by adrenaline. Under the exptl. conditions the influence of the oxidation-promoting action of adrenaline is hardly perceptible. An injection of 0.5, 0.75, 1.0 or 2.5 mg. histamine per kg. immediately raised the o-r p.'s of the lungs and liver and lowered those of the muscle and subcutaneous tissue. The histamine, in general, produced a decrease, followed later by a small increase, in the o-r p. of the spleen and kidneys. These results are due to the action of the histamine on the vascular system and cells. Directly after an injection of 0.5 mg. KCN per kg. the o-r p. of the liver rapidly increased and then gradually decreased, the o-r p. of the kidneys increased, while those of the muscle, subcutaneous tissue and spleen decreased distinctly. In the venous blood the o-r p. underwent a sudden marked fall, followed by a gradual recovery. These changes are probably caused by a direct action of the KCN on respiration enzymes. After the injection of 50 mg. vitamin C per kg. the o-r p.'s of all the organs were generally lowered; in the liver the decrease was slight and followed by an increase. The lowering is attributed to the strong reducing power of vitamin C and the increase is probably due to its oxidation-promoting action. In the organs other than the liver the reducing action predominates over the oxidation-promoting action. Vitamin C markedly detoxicates KCN, has an activating action on respiration enzymes and plays an important role in the o-r processes. **IV. The oxidation-reduction potentials of various organs during serum anaphylaxis in the rabbit.** *Ibid.* 36–7.—In rabbits sensitized with horse serum the o-r p.'s of the liver and lungs were increased, while those of the other organs were not appreciably changed. In general, the o-r p.'s of the organs were increased in the initial stages of anaphylactic shock and then decreased if sufficient anaphylatoxin was present. These changes were evident in all the organs, but the degree of change varied with each organ. The increase was most distinct in the liver, lungs and spleen; e. g., the o-r p. was increased by 50 mv. in the liver and by 28 mv. in the lungs. In the other organs the capacity of the o-r p. to increase is small and, in addn., is suppressed by the action of other factors, so that the o-r p. in these organs is eventually lowered. Ruth Berggren

Sodium chlorate poisoning. Ernest C. McCulloch. *J. Am. Vet. Med. Assoc.* 95, 675–82(1939).—The lethal oral dose of $NaClO_3$ for chicks is slightly greater than 5 mg. per g. of body wt.; for sheep it is between 2.06 and 2.50 mg. per g. of body wt. Rachel Brown

The influence of manganese on body weight and propagation. O. Ehrismann. *Z. Hyg. Infektionskrankh.* 122, 171–88(1939).—The feeding of MnO_2 to white mice increased the body wt. The span of life was not affected. The body wt. of the young of MnO_2-treated females increased rapidly during growth and remained higher in later life than the controls. The litters were reduced from a normal of 4.95 to 4.23. The no. of stillbirths increased almost 40%. The organs of mice fed MnO_2 showed an increased amt. of Mn over normal. Rachel Brown

Burn therapy. M. A. Lesser. *Drug Cosmetic Ind.* 45, 681–3, 686–7(1939).—A review with 22 references. H. M. Burlage

Distribution of intravenously injected silver through the body organs. A. Curatolo. *Atti accad. Lincei, Classe sci. fis., mat. nat.* 29, 522–4(1939).—Using the micro-method (*C. A.* 33, 2928[2]) C. dets. the Ag content of the body of rabbits after injections of Ag (collargol). Most of the Ag is eliminated in the urine. The liver, spleen, lungs, kidneys, bone marrow and heart retain decreasing amts. of Ag, while the brain, testicles and muscles do not retain detectable amts. A. W. Contieri

Intestinal tuberculosis and calcium gluconate. Vito V. Pisani. *Am. Rev. Tuberc.* 40, 571–80(1939).—The conviction that Ca therapy may be of benefit in intestinal tuberculosis is based upon the following considerations: Ca has antiphlogistic and antispasmodic properties, exerting thereby a favorable influence upon the nutritional changes in the tissues; ulceration is mainly due to such changes; it restores the normal Ca-ion concn., thus creating an environment less favorable for the growth and multiplication of the tubercle bacilli; it stimulates phagocytosis; it stimulates fibrosis; above all, it tends to restore the normal physiology of the intestines by counterbalancing the existing vagotonia through the stimulation of the sympathetic filaments. Such a pharmacol. property alone is sufficient to place Ca as an invaluable adjunct in the treatment of intestinal tuberculosis. H. J. Corper

Pleural sensitivity to procaine. K. M. Soderstrom. *Am. Rev. Tuberc.* 40, 733–7(1939).—That it is possible for the pleura of an individual taking pneumothorax collapse therapy to develop a hypersensitivity to procaine local anesthesia was demonstrated by 11 cases observed in the past 2½ yrs. at Firland Sanatorium. This demonstration of sensitivity indicates that procaine and probably all local anesthetics, are causative agents or allergens in the development of a specific hypersensitivity in a certain few patients. H. J. Corper

The treatment of tuberculosis by means of antituberculosis endotoxoid and specific serum. E. Grasset. *Tubercle* 20, 397–419(1939).—Tuberculosis endotoxoid, obtained from the tubercle bacillus by an extn. process of repeated freezing at a low temp. and submitted in the presence of hydrolyzed peptic medium, to the detoxicating action of formalin (0.2%), possesses, in an atoxic nonsensitizing form, high antigenic properties both *in vivo* and *in vitro*. The ext. contains the water-sol. lipoid fraction of the tubercle bacillus and a low bacillary protein content. When injected in doses increasing from 0.05 to 1.5 cc. over a period of several months, endotoxoid exerts a definite therapeutic action in tuberculous patients. The therapeutic action manifests itself in a variety of tuberculous conditions by a general action which is antitoxic, progressive and durable. There is a decrease in temp. and pulse and an increase in wt.; toxic phenomena disappear and the general condition is improved. No contra-indications have been observed. H. J. Corper

Action of neurotropic substances on secretory (salivary) nerves during experimental sensitization. N. G. Ponirovskiĭ and N. Ya. Ganetskaya. *Méd. exptl.* (Ukraine) 1939, No. 4, 1–6.—Expts. were performed on 8 dogs with chronic salivary fistulas. After the salivary response to small doses of a 1% soln. of pilocarpine-HCl was established, horse serum was administered to the dogs according to R. Weil. Observations were made for 90 min. The first (subcutaneous) and second (intravenous) injections of the serum (given 30 min. after the beginning of the salivation induced by pilocarpine) led to increased salivation. In dogs undergoing alternating tests with pilocarpine and adrenaline the second serum injection decreased the salivary response. The third intravenous serum injection produced, after a short period of increased salivation, an inhibition of the pilocarpine salivary response. S. A. Corson

The influence of yellow bone marrow extract on experimental benzene leucopenia. F. Oestreicher. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* 9, 260–3(1939).—The leucopenia and relative lymphopenia produced in rats by subcutaneous administration of benzene are not affected by administration of yellow bone marrow exts. prepd. according to the method of Zichis (*C. A.* 31, 2271[1]). E. Curzon

Effect of treatment with cocaine on the hemostatic action of adrenaline or ephedrine. Gustave Derouaux. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* 9, 266–8(1939).—See *C. A.* 33, 8792[5]. E. Curzon

Toxicity of helminths. R. Mandoul. *Ann. parasitol. humaine et comparée* 17, 187–92(1939).—In *Ascaris megalocephala* there is a material toxic for the guinea pig which is sol. in trichloroacetic acid, in alc. at 50° and is nondialyzable. This substance may be of polypeptide nature. No

such material is found in *Moniesia expansa* or in *Fasciola hepatica*. E. Curzon

Chemotherapy of strongylosis of rats. Albert Erhardt and Karl Denecke. *Ann. parasitol. humaine et comparée* 17, 199–205(1939).—A control method for studies of the chemotherapy of strongylosis of rats is described. A 1:6 combination of ascaridole and CCl_4 had no vermicidal action on *Strongyloides ratti*. E. Curzon

Pharmacology of hydrogen, sulfur and the halogens. Hans Braun. *Süddeut. Apoth.-Ztg.* 79, 805–9(1939).—Twenty-one references. W. O. E.

Arrest by metallic aluminum of the injurious action of silica dusts on conjunctival tissue. A. Policard and J. Rollet. *Compt. rend. soc. biol.* 132, 190-2(1939); cf. *C. A.* 33, 7382[7].—Dusts of various silica minerals introduced into the cornea of the rabbit eye as previously described produced much less damage if previously mixed with 10% of Al metal powder. L. E. Gilson

Action of cobalt minerals on conjunctival tissue as observed with the corneal biomicroscope. A. Policard and J. Rollet. *Compt. rend. soc. biol.* 132, 192-3(1939); cf. *C. A.* 33, 7382[6].—The powd. minerals were introduced into the rabbit cornea as previously described. Cobaltite (CoAsS) and pitchblende produced no permanent opacity but smaltite from various sources produced a permanently opaque spot in all cases. L. E. Gilson

Action of sodium thiosulfate on coproporphyrinuria in experimental lead poisoning in [adult] rabbits. Léon Binet, L. Pérel and Geneviève Glotz. *Compt. rend. soc. biol.* 132, 195–6(1939); cf. *C. A.* 33, 8797[1].—The intraperitoneal injection of 0.2 g. Pb acetate causes the appearance of coproporphyrin in the urine within 48 hrs. The coproporphyrinuria persists for weeks if not treated but disappears in 2 days if about 1 g. of $Na_2S_2O_3$ is injected daily. L. E. Gilson

Effects of extract of Rauwolfia heterophylla on the cardiac vagus. Raymond-Hamet. *Compt. rend. soc. biol.* 132, 213 16(1939); cf. *C. A.* 33, 1038[8].—In dogs small doses of the ext. did not affect the excitability of the cardiac vagus, but large doses completely abolished the cardiac effects of faradization of the peripheral end of the cut nerve without affecting the sensitivity to injections of acetylcholine. L. E. Gilson

Parasympathomimetic drugs and intrapleural pressure. Jean Troisier, Maurice Bariéty and Denyse Kohler. *Compt. rend. soc. biol.* 132, 255-9(1939); cf. *C. A.* 33, 9441[2].—In dogs large intravenous doses of eserine, acetylcholine and pilocarpine produced a transient decrease in intrapleural pressure, while small doses sometimes produced a transient increase. L. E. Gilson

The experimental basis for a method for the quantitative evaluation of the effectiveness of chemotherapeutic agents against streptococcus infection in mice. J. T. Litchfield, Jr., H. J. White and E. K. Marshall, Jr. *J. Pharmacol.* 67, 437–53 (1939).—Incorporation of sulfanilamide in the food of mice appears to be the most satisfactory method of maintaining a nearly const. blood concn. of the drug. The mouse eats with sufficient regularity and frequency to insure the continuous presence of sulfanilamide in the intestine. There is no significant difference between prefeeding and immediate treatment with sulfanilamide, but delaying treatment 4 hrs. after infection causes a significant decrease in the no. of mice surviving. L. E. Gilson

Some aspects of the pharmacology of sulfapyridine. E. K. Marshall, Jr., and J. T. Litchfield, Jr. *J. Pharmacol.* 67, 454–75(1939); cf. *C. A.* 33, 3457[1].—Sulfapyridine (I) is more toxic than sulfanilamide (II) for mice, rabbits and dogs on the basis of blood concn. Acetylsulfapyridine is more toxic than acetylsulfanilamide. I is no more depressant to renal function in dogs than II, but when conjugated as acetylsulfapyridine may cause marked lowering of kidney function as detd. by creatinine clearance. Absorption of I from the gastrointestinal tract is slower, less complete and more variable than that of II. I, like II, readily penetrates all tissues and body fluids, reaching concns. not far from that in the blood, but unlike II it is usually present in higher concn. in the liver than in other tissues. The mode of excretion of I is like that of II. L. E. Gilson

Detoxication by finely dispersed oil-in-water emulsions and their intravenous use. A. C. Frazer and V. G. Walsh. *J. Pharmacol.* 67, 476–86(1939); cf. *C. A.* 33, 4279[9].—The emulsions contained 5% of olive oil in globules less than 0.5 μ in av. diam. (cf. *C. A.* 29, 4475[8]). The detoxicating action on diphtheria and tetanus toxins is independent of either the alky. or the soap content of the emulsion. The toxin is adsorbed on the surface of the oil globules. When 2 toxins are added successively to the emulsion the first is detoxified and the second is not. The antigenic properties of the adsorbed toxin are not affected. The oil globules are too small to cause fat embolism. Inclusion of oxidative catalysts in the emulsion must be avoided since the oxidation products are toxic. The usual adult human dose is 20 cc. intravenously repeated *ad lib.* L. E. G.

Prolonged administration of large doses of acetanilide in monkeys with special reference to blood changes. Paul K. Smith. *J. Pharmacol.* 68, 1–13(1940).—The principal effects of the long-continued administration of extremely large doses of acetanilide were an increase in the rate of red cell destruction and the conversion of part of the hemoglobin to forms incapable of combining with O. In monkeys ingesting 100 mg./kg. daily for 18 weeks the hemopoietic organs were able to keep pace with blood destruction, but doses 5 times as large produced anemia. Little tolerance, no addiction and no electrocardiographic abnormalities were observed. The larger doses caused no significant damage to any organ except that considerable hemosiderin-like pigment was deposited in the liver. Fifty references. L. E. Gilson

Responses of intestinal smooth muscle of the dog to benzedrine sulfate. Alfred Farah and J. O. Pinkston. *J. Pharmacol.* 68, 14–21(1940).—Isolated segments of intestine from dogs 3–12 weeks old were used. The usual response to benzedrine sulfate in concns. of 0.3–150 γ per cc. bath fluid was a decrease in tone and in the amplitude of the pendular and peristaltic movements. The colon was much more sensitive than the small intestine. In live dogs doses of 0.25–5.0 mg./kg. had an inhibiting action on intestinal contractions. L. E. Gilson

Effect of added glucose on rate of appearance of free sugar in liver pulp. S. Soskin, R. Levine and M. Taubenhaus. *Proc. Soc. Exptl. Biol. Med.* 42, 689–92(1939).—Added glucose delays the appearance of free sugar, probably by inhibiting the first step in glycogenolysis (phosphorylation). **Effect of insulin on rate of appearance of free sugar in liver pulp.** M. Taubenhaus, R. Levine and S. Soskin. *Ibid.* 693–5.—Insulin inhibits glycogenolysis in the hashed liver if injected into the dogs 30–45 min. before removal of the liver, and reinforces the retarding action of added glucose. Insulin added directly to hashed liver *in vitro* has no such inhibiting action. L. E. G.

Response to type I pneumococcal vaccine of persons belonging to different blood groups. Victor Ross. *Proc. Soc. Exptl. Biol. Med.* 42, 710–12(1939).—Little or no difference was found. L. E. Gilson

Effect of desoxycorticosterone acetate on plasma volume in patients during ether anesthesia and surgical operation. Chas. Ragan, Joseph W. Ferrebee and G. W. Fish. *Proc. Soc. Exptl. Biol. Med.* 42, 712–16(1939).—The subcutaneous injection of 16–20 mg. desoxycorticosterone acetate 3–4 hrs. before operating under Et_2O anesthesia prevented the decrease in plasma vol. which usually occurs. The injection of crotin immediately before anesthetization gave inconclusive results. L. E. Gilson

Effect of fluoride on solubility of enamel and dentine. J. F. Volker. *Proc. Soc. Exptl. Biol. Med.* 42, 725–7 (1939).—Powd. human tooth enamel and dentine were much less sol. in AcOH-AcONa buffer of pH 4 after having been washed with 0.1% NaF soln. L. E. Gilson

The fresh-water annelid, Tubifex, as a pharmacological test object. James C. Rice. *Proc. Soc. Exptl. Biol. Med.* 42, 727–8(1939).—The animal is injured by low concns. of phosphate ion and by Cl_2 and chloramines in the concns. sometimes present in tap water from a chlorinated water supply. L. E. Gilson

A pressor substance produced by anaerobic autolysis of renal cortex. Joseph Victor, Alfred Steiner and David M. Weeks. *Proc. Soc. Exptl. Biol. Med.* 42, 767–9(1939). Anaerobic autolysis of renal cortex or cell-free renal cortex ext. of the dog produces a powerful heat-stable pressor substance that passes through a collodion membrane. Oxygen inhibits its formation. The substance produces an immediate effect when injected intravenously and the effect is more sustained in hypertensive than in normal dogs. L. E. Gilson

Effect of testosterone propionate on creatinuria. J. R. Coffman and F. C. Koch. *Proc. Soc. Exptl. Biol. Med.* 42, 779–82(1939).—Castration of adult male rats does not alter creatine excretion. Normal and castrated rats react in a similar fashion to exogenous creatine and testosterone propionate as far as creatine and excretion and wt. changes are concerned. Ingested creatine produces an intense creatinuria which is greatly inhibited by testosterone propionate. L. E. Gilson

Specific chemotherapy of experimental staphylococcus infections with thiazole derivatives of sulfanilamide. O. W. Barlow and E. Hombuiger. *Proc. Soc. Exptl. Biol. Med.* 42, 792–7(1939).—"Sulfathiazole" (2-sulfanilamidothiazole) and "sulfamethylthiazole" (2-sulfanilamido-4-methylthiazole, cf. *C. A.* 33, 7795[8]) prolong the lives of mice infected with a highly virulent strain of *Staphylococcus aureus* and prevent the development, or allow the healing, of abcesses in kidneys and other organs. "Sulfaphenylthiazole" (2-sulfanilamido-4-phenylthiazole) is less effective. L. E. Gilson

Effectiveness of neoarsphenamine, sulfanilamide and sulfapyridine in marrow cultures with staphylococci and α-streptococci. Edwin E. Osgood. *Proc. Soc. Exptl. Biol. Med.* 42, 795–7(1939); cf. *C. A.* 33, 6374[9].—In cultures of living human marrow inoculated with hemolytic *Staphylococcus aureus* or *Streptococcus viridans* neoarsphenamine in concns. of 3–9 p. p. m. was far more effective than 1:10,000 concns. of either sulfanilamide or sulfapyridine, and did not significantly damage marrow cells. L. E. Gilson

Mechanism of the therapeutic effect of metrazole and insulin convulsions. E. Spiegel and M. Spiegel-Adolf. *Proc. Soc. Exptl. Biol. Med.* 42, 834–6(1939); cf. *C. A.* 33, 8809[4].—Preliminary discussion. L. E. Gilson

Comparison of certain pharmacological and antibacterial properties of *p*-hydroxylaminobenzenesulfonamide and sulfanilamide. A. Calvin Bratton, H. J. White and E. K. Marshall, Jr. *Proc. Soc. Exptl. Biol. Med.* 42, 847–53 (1939).—The prepn., properties, stability and colorimetric analysis of *p*-hydroxylaminobenzenesulfonamide are described. It is not particularly toxic to animals. When injected into dogs it appears to be completely converted into sulfanilamide within 5 min. Tested against β-hemolytic streptococcus *in vitro* it is not more than 10 times as active as sulfanilamide. L. E. Gilson

Acute toxicity of mononitrobenzene in mice. Michael B. Shimkin. *Proc. Soc. Exptl. Biol. Med.* 42, 844–6(1939). —Painting a large area of the abdomen with $PhNO_2$ killed most of the mice in 1–3 days. The subcutaneous injection of 0.025 cc. (dild. with oil) killed all within 48 hrs.; 0.01 cc. killed 2 out of 15. Methemoglobin appeared in the blood and the white corpuscle count decreased markedly. Necrotic changes occurred in the liver. Sublethal doses painted on, or injected into, skin sarcomas and mammary carcinomas had no effect on the growth of the tumors. L. E. Gilson

Pharmacological studies on monosodium phosphate. Sante Gajatto. *Arch. farmacol. sper.* 68, 87–98(1939).—The m. l. d. for rabbits was 1.4828 g./kg. given intravenously. $CaCl_2$ did not prevent death of the animals which had received a lethal dose of the phosphate but it prolonged the period of survival. The disodium phosphate was 3 times as toxic as the monosodium phosphate. Helen Lee Gruehl

Pharmacological determination of the cardiokinetics in avitaminized and hypervitaminized pigeons. Vittorio Erspamer. *Arch. farmacol. sper.* 68, 150–4(1939).—The min. emetic dose of ouabain was practically the same in normal pigeons and in those with avitaminosis or hypervitaminosis B_1. The changes thus produced in the sensitivity and excitability of the nervous system regulating vomiting did not seem to modify the exptl. conditions. Helen Lee Gruehl

Pharmacology of *p*-succinylaminophenylsulfonamide. Luigi Liaci. *Arch. farmacol. sper.* 68, 155–62(1939).—This drug was widely distributed throughout the body tissues and fluids with concns. decreasing in the following order: bile, kidneys, aqueous humor, blood, spleen, synovial fluid, lungs, ovaries, liver, brain and cartilage. It was eliminated largely through the biliary tract. Helen Lee Gruehl

Influenza virus and sulfonamide preparations. Marcello Perez. *Boll. soc. ital. biol. sper.* 14, 536–8(1939).—Di-Na 4'-sulfonamidophenylazo-7-acetylamino-1-hydroxynaphthalene-3,6-disulfonate, *p*-succinylaminophenylsulfonamide and pure paraminosulfamide were most effective in rats in combating pneumonia from the influenza virus when used in doses of 0.1 cc. (25% soln.) per day. Pure paraminosulfamide gave the best results. H. L. G.

Pharmacodynamic action of derivatives of the octyl series. I. Action on isolated guinea-pig intestines. F. Cavalli. *Boll. soc. ital. biol. sper.* 14, 550–2(1939).—Primary octyl ether and alc. inactivated smooth muscle to subsequent $CaCl_2$ stimulation; octyl bromide and thiocyanate exerted a more marked effect on the tonus than on the contractions; methyloctylamine increased the contractions at first and then gradually diminished their amplitude with no effect on the tonus; primary octylamine, secondary octylamine and diethyloctylamine increased the amplitude of the contractions. Helen Lee Gruehl

Some pharmacological properties of the "diethylaminoethyldiphenylacetate and phenylethylbarbituric acid" combination. F. Cavalli. *Boll. soc. ital. biol. sper.* 14, 552–3(1939).—The assocn. stimulated the medullary centers, the autonomic nervous system and smooth muscle. Its toxicity was the mean of its components. No cumulative effect was demonstrated in animals. H. L. G.

Action of mercurial diuretics on the elimination of uric acid in normal persons and in those with liver disease. Alfredo Ferrannini and Giacomo Fontana. *Boll. soc. ital. biol. sper.* 14, 557–8(1939).—In both instances the mercurial substances increased the vol. of urine and the elimination of chlorides and uric acid. Helen Lee Gruehl

Hydrocyanic acid and its toxic action. V. K. Solov'ev. *Khimiya i Oborona* **1938**, No. 11, 20–1; *Khim. Referat. Zhur.* 2, No. 4, 70(1939).—The properties and the physiol. action of HCN are described as well as the characteristic signs of its poisoning. Methods of protection against HCN and of first-aid treatment are explained. W. R. Henn

Fatal accidents with local anesthesia. Georges Canuyt. *Anesthésie et analgésie* 5, 161–256(1939).—This report summarizes clinical and exptl. observations on fatalities following local anesthesia by cocaine and procaine, discusses methods of preventing such accidents, and presents the medico-legal aspects of the subject. The incidence of local anesthesia mortality, not precisely known, is very small but nevertheless is far higher than would occur if proper dosage and technique were used. Adrenaline apparently is not responsible for deaths due to local anesthetic solns., but on the contrary renders such solns. less toxic. Bibliography. Marion Horn

Comparative action of the hydrochlorides of *d*-, *l*- and *r*-ephedrines on the nerve fiber. F. Meidinger. *Anesthésie et analgésie* 5, 273–6(1939).—In producing local anesthesia in the frog sciatic nerve trunk and the rabbit corneal nerve endings, *l*-ephedrine > *r*-ephedrine > *d*-ephedrine. The compds. act additively with scurocaine and cocaine in producing local anesthesia, but do not potentiate these drugs. Marion Horn

Use of ethyl bromide in practical obstetrics. J. Lerouge. *Anesthésie et analgésie* 5, 303–10(1939).—Highly purified EtBr (I) has been found preferable to EtCl (II) for use as an analgesic in labor, since the excitation phase seen with II does not occur with I. I is as rapid in effect as II, producing analgesia in 40 sec. and uterine relaxation in 110

sec. The patients resume consciousness rapidly between whiffs but exhibit amnesia. Toxic accidents previously observed with I are believed by L. to have been due to impurities. Marion Horn

A peculiar form of intoxication with rubiazole. M. van der Meiren. *Arch. belges derm. syph.* **1**, 226; *Brit. J. Dermatol. Syphilis* **51**, 495(1939).—Administration of 4–6 tablets of rubiazole (carboxysulfamidochrysoidine) 4–5 days a week for 2 months led to sudden appearance of ascites, hydrothorax and edema. Much of the serum protein was found to have been transferred to the edema fluid. The patient recovered in 2 weeks after discontinuation of the drug. Marion Horn

Some cases of barbiturate poisoning. G. Giraud, P. Mas, Merle, Sentein and Boisbeunet. *Arch. soc. sci. méd. biol. Montpellier et Languedoc* **20**, 413–14(1939).—Six cases of barbiturate poisoning are reported. Two patients died after ingestion of 6 g. gardenal (I) and an unknown dose of (probably) I, resp. Four recovered after ingestion of an unknown dose of barbital (II), an "entire flacon" of somnifen (III), 0.5 g. II + 0.5 g. $HgCl_2$, and an unknown dose of II + 20 aspirin tablets, resp. Intravenous strychnine therapy was used in the first 5 cases. The patient recovering after III poisoning had frequently taken medicinal doses of III and I. Marion Horn

Variations in the gaseous composition of the blood after the injection of insulin in schizophrenia. I. M. F. Merezhinskiĭ, A. S. Cherkasova and I. A. Sazanskiĭ. *J. méd., Ukraine* **9**, 395–401(in French 401)(1939).—The injection of insulin (I) into schizophrenic patients generally causes an increase in O_2 in venous blood, the max. corresponding to the point at which hypoglucemia is most marked. Variations in CO_2 showed no general trend, while N_2 showed little change. The injection of glucose after I results in a decrease in the O_2 in venous blood. II. *Ibid.* 403–10(in French, 410).—The O_2 content of venous blood falls immediately after injection of I, and begins to rise only after 1.5–2.5 hrs. The max. value is approx. 19% above its initial value. The O_2 difference in arterial and venous bloods before injection of I is within the limits 7.23–14.83 vol. %, while at the point of shock the difference is only 0.71 vol. %. S. A. Karjala

The blood supply of the tissues of the organism at high altitudes and its changes after caffeine administration. I. P. Baĭchenko, G. E. Vladimirov, I. M. Dedyulin, L. I. Ostrogorskaya and Ya. A. Epshtein. *Klin. Med.* (U. S. S. R.) **17**, No. 11, 99–112(1939).—The difference in O_2 content of arterial and venous bloods decreases at high altitudes. A slight increase in arterial pressure is also observed. After acclimatization the minute vol. of the heart decreases but never reaches the value normal at sea level. The administration of 0.2–0.4 g. of caffeine causes a greater increase in the minute vol. of the heart at high altitudes than at sea level. S. A. Karjala

Relation between the trypanocidal and spirocheticidal activities of neoarsphenamine. V. Spirocheticidal activity of the several American brands of neoarsphenamine. T. F. Probey. *U. S. Pub. Health Repts.* **54**, 2242–7(1939); cf. *C. A.* **27**, 4301.—The min. effective dose of neoarsphenamine in exptl. syphilis may vary from test to test, probably because of the variable factors in the exptl. infection to which the virulence of the organism may contribute rather than to differences in curative activity of the drug. Seventeen lots of neoarsphenamine, representing 7 American brands, are recorded as being uniformly active in curing exptl. syphilis in rabbits with one treatment late in the active stage of the disease. Fifteen references. J. A. Kennedy

Effect of sulfapyridine and sulfanilamide with and without serum in experimental meningococcus infection. Sara E. Branham. *U. S. Pub. Health Repts.* **55**, 12–25(1940).—Extremely small amts. of these drugs give some protection in mice. Wt. for wt., sulfapyridine has a protective action about 10 times that of sulfanilamide but the action of the former is somewhat less regular. There is a variation in response to the drugs by individual strains of the meningococci. For some strains, serum therapy was more successful; for others the drugs have been far better. Combination of either of the drugs with serum has given results far better than with either agent alone. One serum had practically no protective action on any strain when used alone, but marked protection could be obtained when it was given with the drugs. Normal horse serum gave no protection with the drugs. It seems reasonable to treat patients with the combined therapy unless some contraindication is known. Eighteen references. J. A. Kennedy

Metabolism of pyruvic acid in man. P. E. Simola and F. E. Krusius. *Z. physiol. Chem.* **261**, 209–24(1939); cf. *C. A.* **33**, 7141.—After doses of 50 g. of Na pyruvate in men the α-ketoglutaric acid content of the urine increases by 40 times (from 28 to 1243 mg./24 hrs.) in the following 24 hrs. A lesser increase of pyruvic, lactic and citric acids and of acetone body excretions also results. The excretion of α-ketoglutaric acid reaches a max. between the 2nd and 6th hr. after dosing. The citric acid and acetone excretions reach a max. 4–6 hrs. after the dose. A dose of $NaHCO_3$ equiv. to the Na pyruvate caused no increase in α-ketoglutaric acid excretion. Citric acid increased to as great an extent after $NaHCO_3$ as after pyruvate, but the max. occurred between 24 and 48 hrs. after dosage. No increase in acetone bodies followed the $NaHCO_3$ dosage. Milton Levy

The influence of sulfanilamide and similar compounds on anthrax. G. Ivanovics. *Z. Immunitäts.* **96**, 252–4 (1939).—Substances of the sulfanilamide type influence anthrax infections slightly or not at all. J. H. Lewis

The effect of insulin upon urea formation, carbohydrate synthesis and respiration of liver of normal and diabetic animals. Wm. C. Stadie, Francis D. W. Lukens and John A. Zapp, Jr. *J. Biol. Chem.* **132**, 393–409(1940).—Insulin inhibits the deamination of the unnatural *d* isomers of amino acids by isolated liver slices from normal animals, an indication that it may directly influence protein metabolism. The corresponding *l* natural isomers are unaffected and furthermore, in the complete absence of insulin the deamination is much greater than normal. The new formation of carbohydrate by liver slices of normal or diabetic animals is uninfluenced by the addn. of insulin to the equilibrating medium. In the diabetic cat, there was a subnormal formation of new carbohydrate in spite of the high rate of deamination. The "contrainsular" activity of the pituitary was manifested in 2 ways: (*a*) in the hypophysectomized-depancreatized cats the hypernormal deamination by liver slices found in the depancreatized cat was restored to normal; (*b*) diabetic cats receiving prior injections of anterior pituitary exts. showed in 4/5 of the cases hypernormal rates of liver deamination. As a limited working hypothesis, it is suggested that a possible action of insulin is to regulate protein metabolism by partially inhibiting the oxidative deamination of the *d*-isomers of nonglycogenic and glycogenic amino acids. The activity of prepns. of *d*-deaminase was uninfluenced by insulin. **The effect of insulin upon oxidations of isolated minced muscle tissue.** W. C. Stadie, J. A. Zapp, Jr., and F. D. W. Lukens. *Ibid.* 411–21.—The mean O_2 consumption of muscle mince of normal pigeon breast suspended in phosphate buffer at pH 6.8 together with boiled muscle ext. was increased 43% by the presence of citrate. The effect is apparently not catalytic since the excess of O_2 was always less than the O_2 equiv. of the citrate added. Insulin at 1 unit per cc. increased the O_2 uptake 13% (mean) but this effect is apparently independent of the presence of citrate. This effect of insulin was not significantly enhanced when muscle mince from diabetic pigeons or cats was used. Kreb's citrate cycle hypothesis (*C. A.* **32**,7134[2]) and the relation of insulin to it remains a matter for future experimentation. **The effect of insulin upon the ketone metabolism of normal and diabetic cats.** *Ibid.* 423–43.—Ketone utilization by the muscles was calcd. from measurements of (*a*) excess hepatic ketone formation over urinary ketone excretion, (*b*) oxidation of added acetoacetate by muscle mince equilibrated *in vitro*, (*c*) simultaneous equilibration of muscle mince with diabetic liver slices as source of ketones and (*d*) measure-

ment of portal-hepatic blood ketone difference. An av. value of 1300 micromoles per kg. of cat per hr. was found for the utilization of ketones by muscle. Utilization in the diabetic cat was essentially the same as in the normal animal, a demonstration that oxidation of ketones by muscle is independent of the presence of insulin. No utilization of *dl*-β-hydroxybutyrate added to muscle mince could be demonstrated in either normal or diabetic cats, a possible indication that acetoacetate is the sole form of ketone oxidized by muscle. There was found in 4 of 6 cases an increase of both β-hydroxybutyrate and total ketones, evidence that muscle as well as liver may be a source of ketones in the diabetic. The mol. ratio of O_2 consumed to ketone produced from fat acids by the liver was close to the value of 1.25 required by the "multiple alternate oxidation" hypothesis of Jowett and Quastel (*C. A.* **30**, 1427[9], 1428[5,6]). This is evidence that the higher fat acids yield not 1 but 4 mols. of ketones per mol. of acid oxidized. On the basis of the observed O_2 to ketone ratio, it is possible to calc. the non-ketone respiration of the liver and contrast its characteristics in the fasted normal, the diabetic and the insulin-treated diabetic cat. The non-ketone O_2 available for the possible oxidation of fat acids to carbohydrates is essentially zero, an indication that the hypothesis of the overproduction of carbohydrates from fats in diabetes is untenable. Insulin in the presence of fructose, fumarate and *d*-lactate inhibited the formation of ketones by the diabetic liver. The effect was enhanced by prolonged equilibration of slices with insulin-contg. media. Prior insulin treatment of diabetic cats restored the metabolism of the liver slice to a status intermediate between the normal and the diabetic. There was a marked reduction of ketone formation and a type of nonketone respiration suggesting partial oxidation of fat acids beyond the ketone stage. In Houssay cats (hypophysectomized and pancreatectomized) ketone formation by the liver was essentially that of the fasted normal cat, a suggestion that insulin controls ketone formation indirectly by acting antagonistically to the ketogenic pituitary hormone. A. P. Lothrop

Hyperglucemic effect of cobra venom in the guinea pig and rabbit. Gabriel Bertrand and Radu Vladesco *Compt. rend.* **209**, 585-7(1939).—Injection of cobra venom causes hyperglucemia in guinea pigs and rabbits, while unfiltered suspension of dried horse serum does not. J. McAfee

The effects of 3,4-benzopyrene on human skin. Gian Battista Cottini and Gian Battista Mazzone. *Am. J. Cancer* **37**, 186-95(1939).—Daily application of a 1% soln. of benzopyrene (I) in C_6H_6 to the skin caused erythema, pigmentation, desquamation, formation of verrucae and infiltration, in chronological order. These manifestations regressed when treatment was discontinued and seemed to represent prototypes of a precancerous process. In patients with pemphigus vulgaris, treatment with I caused a bullous eruption comparable to the spontaneous disease. The treatment caused temporary amelioration of squamous-cell cancer and a retardation in the progress of mycosis fungoides lesions. Basal-cell cancer, desquamating lesions of psoriasis and xeroderma pigmentosum were unaffected by I. E. R. Main

Cyanosis caused by sulfonamide compounds. David Campbell and Thomas N. Morgan. *Lancet* **1939**, II, 123-7.—Either methemoglobin or sulfhemoglobin is found in the blood during the cyanosis which develops during treatment with sulfanilamide or sulfapyridine. The methemoglobinemia is reduced after oral or intravenous administration of methylene blue while the sulfhemoglobinemia is unaffected. Methylene blue removes methemoglobin formed as a result of administration of nitrite to rabbits or prevents formation of methemoglobin when injected simultaneously with nitrite. E. R. M.

The effect of sulfonamides on blood serum. G. Allan Scott and O. Meerapfel. *Lancet* **1939**, II, 244-6.—Two cases are described in which prolonged treatment with sulfonamide derivs. led to an alteration in the blood serum which precluded the finding of suitable donors for blood transfusion. Normal serum treated for 4 days *in vitro* with sulfanilamide in a concn. of 2.5% agglutinated blood cells of donors of the corresponding blood group and also cells of universal donors. E. R. Main

Encephalomyelitis following administration of sulfanilamide. J. H. Fisher, M. B. Sydney and J. R. Gilmour. *Lancet* **1939**, II, 301-5.—Two cases are described. E. R. Main

Chemotherapy of experimental anthrax infection. J. C. Cruickshank. *Lancet* **1939**, II, 681-4.—Sulfanilamide and sulfapyridine (I) were therapeutically effective in anthrax infection in mice, the latter having the greater effect. With moderate doses, 10-20 mg. I daily, the survival time was lengthened and, with very large doses, complete curative effect was obtained in about 1/3 of the treated mice. Neoarsphenamine and tryparsamide tested in the same manner had no significant effect. E. R. Main

Action of the sulfonamides in experimental anthrax. H. B. May and S. C. Buck. *Lancet* **1939**, II, 685-6.—Treatment with sulfanilamide, sulfapyridine (I) or 4,4′-diaminodiphenyl sulfone glucoside delayed death in mice infected with anthrax bacilli, but no ultimate decrease in mortality was found. I was more effective than the other compds. Two commercially available anthrax antiserums had no protective action in mice. An antiserum prepd. in the rabbit gave a high degree of protection, which was not increased by use in combination with I. E. R. Main

Hematuria during treatment with M. and B. 693. T. C. Backhouse. *Lancet* **1939**, II, 736-8.—Hematuria was observed in 13 of 109 cases of pneumonia in Melanesian natives treated with sulfapyridine (I). The hematuria was assocd. with the appearance of crystals of the acetyl deriv. of I in the urine. In one case without hematuria, small calculi were found obstructing both ureters. E. R. Main

Granulopenia following administration of M. and B 693 (sulfapyridine.) G. O. A. Briggs. *Lancet* **1939**, II, 739-40. E. R. Main

Chemotherapy of meningococcal meningitis. A review of 147 consecutive cases. H. Stanley Banks. *Lancet* **1939**, II, 921-6.—In 65 cases treated with serum and sulfanilamide (I) the fatality was 12.3%. In 72 cases treated with I, sulfapyridine, or a combination of the 2, the fatality was 1.4%. The initial dosage of the drugs should be sufficient to maintain a concn. of at least 5 mg.% in the cerebrospinal fluid for 3 days, with a lower concn for a further period of 5-6 days. Groups I and II meningococci were equally susceptible to chemotherapy. E. R. Main

Effects of drugs in myotonia. E. Guttmann and A. B. Stokes. *Lancet* **1939**, II, 979-81.—Administration of quinine-HCl caused definite improvement in myotonia. Neither prostigmine nor benzedrine was effective. E. R. Main

Renal calculi following alkali therapy. Thomas Moore. *Lancet* **1939**, II, 1118-19.—Two cases are described in which primary stones were formed as a result of excessive consumption of alk. mixts. in the course of treatment of peptic ulcer. E. R. Main

Clinical studies in acidosis and alkalosis; use and abuse of alkali in states of bicarbonate deficiency due to renal acidosis and sulfanilamide alkalosis. Alexis F. Hartmann. *Ann. Internal Med.* **13**, 949-56(1939).—Plasma $BHCO_3$ reduction may occur in chronic nephritis and other forms of renal insufficiency, with a production of a real acidosis of the "metabolic type" without abnormal acid retention. This is due to inadequate reabsorption of $BHCO_3$ by the renal tubules from the glomerular filtrate. Severe and persistent acidosis was noted in an infant of 4 months when the only demonstrable renal lesion was failure of the tubules to reabsorb $BHCO_3$. The administration of alkali, especially *r*-lactate, in such cases will relieve and prevent recurrence of significant acidosis. Plasma $BHCO_3$ reduction which follows sulfanilamide administration is compensatory for a primary CO_2 deficit owing to alkalosis and is not relieved by alkali. John T. Myers

Picrotoxin in the treatment of acute barbiturate poisoning: a review with report of two cases. Edward C. Reifenstein, Jr., Edward C. Reifenstein, Sr., Justin W. Mignault and Angelo J. Raffaele. *Ann. Internal Med.* **13**, 1013-27

(1939).—Picrotoxin is effective in acute barbiturate intoxication. 27 references. John T. Myers

The influence of emulsions of olive oil on the biological actions of alkaloids. G. Norman Myers. *J. Hyg.* **39**, 705–15(1939).—When alkaloidal salts of arecoline, pilocarpine, atropine, morphine, diacetylmorphine or strychnine were mixed with olive oil emulsions in a fine state of division, allowed to stand at 37.5° for varying times up to 24 hrs. and then injected into animals, their biol. activity was apparently unchanged. This suggests that the droplets of the emulsion do not have the power of adsorbing alkaloidal salts at their surfaces. Arecoline-HBr when mixed with olive oil and injected intravenously sometimes showed a pressor action in chloralized cats, whereas an aq. soln. always produces the normal depressor effect. J. T. M.

The toxicity of indene. G. R. Cameron and Cecile R. Doniger. *J. Path. Bact.* **49**, 529–33(1939).—Indene exerts toxic effects on rats, mice and guinea pigs, such as liver necrosis, sometimes of the cytolytic type (acute yellow atrophy), less frequently splenic and renal focal necrosis. No changes were noted in the blood or in other organs. Toxic effects are produced only by exposure to high concns. or by the administration of large amts. Hence it is not a highly noxious agent. However, limits should be set for its use in insecticides. John T. Myers

Responses of the human post-partum uterus to posterior pituitary extracts. Sprague Gardiner and James T. Bradbury *Am. J. Obstet. Gynecol.* **39**, 1–10(1940).—There are considerable differences in the uterine responses of the post-partum patient and of the lab. animal to posterior pituitary exts. Therefore the present methods of com. assay using the virgin guinea-pig uterus are not an index of the actual clinical oxytocic potency of pitressin (I). Since 1 cc. of a 1:100 diln. of either I or pitocin (II) has been found to be the usual min. oxytocic dose in human subjects, a human oxytocic unit is approx. 0.01 cc. of pituitrin, I or II, and is equiv. to 0.1 international oxytocic unit. J. Pinchack

Alcohol tolerance: its importance in relation to chemical tests for drunkenness. Henry W. Newman. *Calif. and Western Med.* **52**, 9–11(1940).—The chem. diagnosis of drunkenness is inconclusive unless confirmed by clinical observation or performance tests. This assumption is based on the fact that dogs show a tolerance to alc. which varies from animal to animal, and which increases with habituation and decreases with abstinence. J. P.

Sulfanilamide therapy—a review of the literature. Joseph C. Doane, Nathan Blumberg and J. George Teplick. *Med. Record* **151**, 439–43(1939). J. P.

Topical dentine anesthesia. Harold A. Ossenman. *N. Y. J. Dentistry* **9**, 383–6(1939).—Directions are given for the anesthetization of dentine by: (1) a surface-tension depressant, detergent and dehydrating agent composed of 3 parts $CHCl_3$, 1 part EtOH and 1% (all portions by vol.) of a 25% aq. soln. of "sodium diamyl carbinyl sulfate"; (2) a liquid compn. of 5% thymol, 4% benzocaine and 4% (all % by wt.) of (1) contg. 2 instead of 1% diamyl compd.; and (3) a paste composed of 1 part thymol, 1/4 part thymyl *p*-aminobenzoate and 2 parts (all parts by wt.) benzocaine. J. Pinchack

The clinical use of sulfamethylthiazole in infections caused by Staphylococcus aureus: Preliminary report. W. E. Herrell and A. E. Brown. *Proc. Staff Meetings Mayo Clinic* **14**, 753–8(1939).—Exptl. results in mice (total dose, 18 g. drug/kg.) as well as preliminary clinical work (1 case) indicate that 5-methylsulfathiazole is a rather efficient drug in infections caused by pneumococcus and especially *Staphylococcus aureus* at a much lower toxicity than that found for sulfapyridine. J. P.

The toxicity for human beings of diethylene glycol with sulfanilamide [Senate Document No. 124]. Herbert O. Calvery and Theodore G. Klumpp. *Southern Med. J.* **32**, 1105–9(1939); cf. Cannon, *C. A.* **32**, 1333[6]; Lynch, *C. A.* **32**, 8562[1].—The 105 fatalities and 260 survivals following the ingestion of the diethylene glycol elixir of sulfanilamide released in 1937 are analyzed graphically as to distribution of dosage. A varying tolerance to the solvent was indicated, most individuals surviving doses fatal to others. J. Pinchack

Sulfamethylthiazole. A report of its clinical use in staphylococcus septicemia with apparent success. A report of animal experiments. Grayson Carroll, Louis Kappel, Lloyd Jones, Fred W. Gallagher and Francis W. DiRocco. *Southern Med. J.* **33**, 83–7(1940).—The first 5 cases of *Staphylococcus aureus* infection to be cured by 5-methylsulfathiazole (2-g. doses given orally) or its Na salt (250–500 mg. given intravenously) are presented. About 70% of the white mice injected with a lethal dose of staphylococci were saved by the drug or its Na salt, given for 10–15 days. Similar results were obtained in rats and rabbits. J. Pinchack

Results of intravenous and intra-arterial administration of fluids in traumatic shock produced experimentally. Douglas B. Kendrick, Jr. *Surgery* **6**, 520–3(1939).—The intravenous route of administering a 5% *d*-glucose soln. in saline soln. is preferable to the intra-arterial in averting exptl. shock in dogs. Shock due to intestinal trauma developed several hrs. earlier under ether than under sodium pentobarbital anesthesia. J. P.

The activity of isolated segments of the colon of dogs, with special reference to the influence of certain drugs. Robert E. Reagan and Charles B. Puestow. *Surgery* **6**, 663–78(1939).—Pitressin (20 pressor units) increased the tonus of isolated, surviving segments of the dog colon, but had very little effect on its movements. Morphine sulfate (0.4 and 0.8 mg./kg.) increased the tonus and the frequency and strength of contractions. Atropine sulfate (0.016 mg./kg.) had little if any effect on motility. Prostigmine gave the most uniformly strong contractions of all the drugs used. The effects of 1 cc. of a 1:2000 soln. varied from marked increase in tonus to tonic contraction. Physiol. saline soln. had very little if any effect on colonic motility, but 10–20% solns. markedly increased tonus and the no. and strength of contractions. A short increase in colonic movement was caused by 20 cc. of a 50% glucose soln. The last 2 drugs were given intravenously, the others intramuscularly. The above results were also obtained when the colonic mesentery was previously cut. J. Pinchack

Studies of intestinal motility: the effect of intravenous solutions and of insulin upon peristalsis. Wm. P. Kleitsch and Charles B. Puestow. *Surgery* **6**, 679–96(1939).—Intestinal motility being related to surgical complications, the effects of intravenous solns. commonly used in surgery and of insulin upon peristaltic rate and intestinal tonus were detd. on isolated intestinal transplants of dogs. Physiol. saline soln. definitely increased the rate and strength of peristaltic contractions. Dextrose (10% soln.) alone was practically ineffective, but when combined with physiol. saline displayed definite enterokinetic properties. Insulin progressively decreased peristaltic rate and intestinal tonus. When given with 10% dextrose soln., it decreased intestinal tonus and strength of contractions and slightly reduced the peristaltic rate. Each expt. is preceded by a literature review. J. Pinchack

Influences of local asphyxia, organ extracts and temperature changes on engrafted subcutaneous and visceral tumors in rats. Frederick M. Allen. *Urol. Cutaneous Rev.* **44**, 12–18(1940).—Very powerful destructive effects upon exptl. visceral tumors were occasionally produced by heat or cold. The results are not specific or controllable enough for practical application. Pancreatin, peptone, insulin, adrenaline, anterior or posterior pituitary emulsions and adrenal cortical ext. exhibited no specific tumor-killing action. J. Pinchack

Tryparsamide in the treatment of syphilis. A review of the literature. Josephine Hinrichsen. *Venereal Disease Information* **20**, 293–322(1939).—175 references. J. P.

Experimental studies on the effect of glutathione and vitamin B in infections. J. v. Deschwanden. *Schweiz. med. Wochschr.* **69**, 642–6(1939).—Irradiated yeast, rich in vitamin B and glutathione, did not affect the resistance of rabbits to the pyretic action of dinitrophenol but it did show a favorable influence against infection with virulent

Staphylococcus albus as compared to control expts. Glutathione increases bactericidal power and antibody formation. Vitamin B is important for its interrelationships to other vitamins and the endocrine system. Twenty-two references. Maurice M. Rath

Experimental chronic cadmium poisoning. Robert H. Wilson and Floyd DeEds. *Science* 90, 498(1939).—$CdCl_2$ was added to the diet of albino rats in concns. ranging from 0.0031 to 0.05%. The symptoms of toxicity observed were bleaching of the enamel of the teeth, anemia and cardiac hypertrophy. The bleaching of the teeth is similar to, if not identical with, that produced by fluorides and occurs at all dosage levels. The degree of bleaching is proportional to the dosage. The anemia is likewise present at all levels and the severity increases with the increase in the dosage. The cardiac hypertrophy is most evident on concns. of 0.0062, 0.0125 and 0.025%, and less evident at a concn. of 0.05% because the rats die before the hypertrophy can fully develop. Felix Saunders

Influence of simultaneous administration of calcium and phosphorus salts on the calcium and phosphorus levels of the serum. Min Sen Li. *Monatsschr. Kinderheilk.* 79, 317–22(1939).—A prepn. called "tricalcol," contg. Ca and P bound to colloidal proteins, was administered by mouth to healthy and sick infants. To a group of 6 healthy infants 15 g. of tricalcol was given in 1 dose. After 3 hrs. the serum Ca began to rise and was found at a peak of 11.8–13.7 mg. % after 5 to 7 hrs.; it returned to normal after 24 hrs. The serum P was somewhat depressed. To another group of 6 healthy infants 5 g. tricalcol was given 3 times a day over a period of 8 days. In the course of 4 days, the serum Ca rose to between 12.2 and 13.3 mg. % on fasting and stayed there until administration of the prepn. was stopped; it returned to normal by the 14th day. The serum P was depressed to from 2.5 to 4 mg. %. A third group of infants with rickets (4 cases) and rickets plus tetany (6 cases) received 5 g. tricalcol 3 times a day for 10 days. The serum Ca slowly rose from subnormal figures (7–9 mg. %) to normal ones (9 to 11.5 mg. %) within 8 days; the serum P remained low. In a few cases a drop of the serum Ca was observed after tricalcol was stopped. The slow action of the prepn. renders it unfit for practical application. H. P. G. S.

The calorigenic action of adrenaline: proportionality with dose. Fred. R. Griffith, Jr., F. E. Emery and Julia E. Lockwood. *Am. J. Physiol.* 128, 281–90(1940); cf. *C. A.* 33, 9454⁹.—Intravenous injection of adrenaline at rates of 0.00025, 0.00050, 0.00100, 0.00200, 0.00400, 0.00700 and 0.01000 mg. per kg. per min. for 5 min. affects the O consumption of chloralose-anesthetized cats as follows: The min. effective rate of injection is either 0.00025 or 0.00050 mg. per kg. per min. and more probably the latter. At all rates of injection above threshold, O intake is increased approx. the same amt. (+6 to +8%) during the 5-min. injection period itself. At rates of injection below 0.007 mg. per kg. per min. O consumption continues to increase to a max. 5 to 10 min. after injection is over. The max. calorigenic effect (+16%) occurs at this time after injection at the rate of 0.004 mg. per kg. per min. At the 2 highest rates of injection, 0.007 and 0.010 mg. per kg. per min., O consumption during injection is increased no more and no less than with smaller rates. The total effect following injection is, however, less. The total calorigenic effect for the 35-min. exptl. period increases from threshold to max. at 0.004 mg. per kg. per min. and then decreases progressively at rates beyond this. The calorigenic effect parallels closely in threshold, max. and decline at higher rates of injection, the simultaneous changes in blood-sugar level but is quite unlike the increases in blood lactic acid. E. D. Walter

A statistical study of cobalt polycythemia in the dog. Geo. Brewer. *Am. J. Physiol.* 128, 345–8(1940); cf. *C. A.* 31, 2690⁶.—Co in sufficient dosage causes a significant increase in erythrocyte no., hemoglobin concn. and percentage vol. of packed erythrocytes in the dog without toxic symptoms appearing. Five mg. of Co per kg. of body wt. seems to be close to the crit. concn. required to increase the erythrocyte no. and hemoglobin concn. whereas the hematocrit is increased only by somewhat larger doses. E. D. Walter

Benzedrine and brain metabolism. P. J. G. Mann and J. H. Quastel. *Nature* 144, 943–4(1939).—Benzedrine stimulates the O uptake of brain *in vitro* when this respires in the presence of certain amines. This is accomplished by an inhibition of the formation of toxic aldehydes. E. D. Walter

The treatment of actinomycosis by the intravenous administration of sodium iodide. E. Murray Pullar. *Australian Vet. J.* 15, 104–17(1939).—App. for administering NaI is described and 13 case records are discussed. Colin W. Whittaker

The treatment of babesiellosis (B. argentina) with acaprin. John Legg. *Australian Vet. J.* 15, 121–3 (1939).—Six ml. of acaprin applied subcutaneously to cattle reacting acutely to *B. argentina* caused rapid disappearance of the parasites from the peripheral blood and rapid recovery. Colin W. Whittaker

Protective action of ascorbic acid against intoxication by glucosides of the digitalis group. I. Intoxication by digitalis glucosides and ascorbic acid. Tomaso Galli, Domenico Bussa and Giorgio Montolivo. *Boll. soc. ital. biol. sper.* 14, 547–8(1939).—Ascorbic acid protected guinea pigs from the lethal effects of chronic intoxication with digilanide but did not prevent acute intoxication. It somewhat lessened the effects of acute strophanthin intoxication. **II. Bario-digitalis intoxication and ascorbic acid.** *Ibid.* 548–9.—Ascorbic acid protected guinea pigs from intoxication with small doses of $BaCl_2$ and digitalin (or strophanthin) but with larger doses the increase in survival was inversely proportional to the intensity of the dose. Variations in the water content of the frog. E. F. Adolph. *Ann. physiol. physicochim. biol.* 15, 353–67 (1939).—If the loss in body wt. of the frog exceeds 10%, the renal elimination ceases while the speed of absorption of H_2O through the skin increases considerably. If the H_2O content of the body is excessive, the elimination increases while the absorption remains const. In the frog, for any algebraic change in the H_2O content, the mechanisms which compensate a deficit act more quickly than those which compensate an excess. The polyuria produced by an excess of H_2O is much greater in frogs which are kept in H_2O than in frogs which are not. The results permit a description of the kinetic equil. of the H_2O content. Ruth Berggren

Observations on capitellids, especially their respiration. Arne Lindroth. *Zool. Anz.* 127, 285–97(1939).—Earlier work (*Zool. Bidr. Uppsala* 17 (1938)) showed that under good respiratory conditions *Nereis virens* had regular 5-min. ventilation periods, when the circulation was active and the hemoglobin became satd. to a max. degree, followed by 20-min. rest pauses, when the vascular activity gradually ceased and the O of the hemoglobin was consumed. The respiratory function of the blood and of the circulatory system was mainly that of O storage, the transport func-

tion being subordinate. Expts. on capitellids, especially *Capitella capitata*, indicated that they probably behaved like *Nereis virens*. In order to renew the O supply of the red cells, peristaltic contractions of the abdomen occurred which promoted simultaneously the ventilation of the abdomen with fresh sea water and the circulation of the hemolymph bearing the blood corpuscles. Deterioration of the respiratory medium produced an increased activity of the ventilation mechanism in *Capitella* and finally dyspnea appeared. The periodicity of the O supply was then absent. Cf. *C. A.* **33**, 3896[8]. Ruth Berggren

The effect of colchicine and sex hormones on the oxygen consumption of fish. Hans Mann. *Zool. Anz.* **127**, 315–18(1939).—The O consumption in g. O_2/kg. body wt./24 hrs. of female perch (*Perca fluviatilis*), male bitterlings (*Rhodeus amarus*) and female roach (*Leuciscus rutilis*) were as follows: normal, 1.85, 20.75, 2.1; after intraperitoneal injections of hormones (each perch received 1 cc. follicular hormone (Glandobulin, Richter) which was repeated 4 hrs. later; each bitterling received 0.075 cc. and each roach 1 cc. testicular hormone (Orchitique, Choay), 2.34, 30.95, —; after treatment with colchicine (each perch received an intraperitoneal injection of 1 cc. colchicine (2:1000) which was repeated 4 hrs. later; the bitterlings and roach were kept in a colchicine soln. (0.75:1000) for 90 min.), 2.80, 33.4, 2.50; after combined treatment with colchicine and sex hormones, 2.90, 39, 3.33, resp. The measurements on the perch and roach were made 6–10 hrs. after treatment and those on the bitterlings 24 hrs. after treatment. Similar injections of cond. water produced no change in the O consumption of the fish. The results offer further proof of the synergism of colchicine and the hormones. Ruth Berggren

Relation of blood feeds to the maturation of ova in Anopheles elutus. M. Yoeli and G. G. Mer. *Trans. Roy. Soc. Trop. Med. Hyg.* **31**, 437–44(1938); *U. S. Pub. Health Eng. Abstracts* **18**, Ma, 20 (July 2, 1938).—After the ovaries of *A. elutus* reach a certain stage in development, a blood feed is necessary for the maturation of the ova. In an effort to det. the sp. fraction of blood which is thus required, expts. showed that neither hemoglobin alone nor serum alone is capable of inducing maturation of ova. Hemoglobin can bring the ova only to stage II of development and no further. In this respect hemoglobin is no different from raisins or sugar. If ova at stage II are fed serum, then complete ripening occurs. The sp. egg-maturing factor is present in the stroma of the erythrocytes as well as in the cell-free serum and is active after heating the serum for 1 hour at 100°. In serum coagulated by boiling, the sp. factor is assocd. with the coagulum and is absent in supernatant liquid, whereas the extd. serum is still active. It is not clear whether the substance is an "accessory" or a protein. Lipoids extd. from serum or red cells are inactive, whereas the extd. serum is still active. C. R. Fellers

Variations in the refractory period and chronaxia of fish myocardium under the influence of substances acting on the autonomous nervous system. D. T. Barry, A. Chauchard, B. Chauchard and Paul Chauchard. *Compt. rend. soc. biol.* **132**, 216–19(1939).—Very dil. solns. of acetylcholine or yohimbine salts decreased, and atropine or adrenaline increased, the chronaxia and refractory period of the isolated fish heart. L. E. Gilson

Action of mammalian sex hormones in the lizard, Sceloporus occidentalis. Aubrey Gorbman. *Proc. Soc. Exptl. Biol. Med.* **42**, 811–13(1939).—Adult males and females were treated with theelin and with testosterone propionate. Neither hormone significantly affected the thyroid, adrenals, ovaries or mesonephros. Testes were not affected by testosterone but were slightly reduced in size by theelin. Both hormones produced enlargement of the oviduct. L. E. Gilson

Alternative to cyanide for killing insects. J. E. Campbell-Taylor. *Microscope Entomol. Monthly* **3**, 267(1939). —NH_4OH does not leave insects stiff and rigid after killing as does $CHCl_3$, and is preferred to the highly poisonous KCN. An app. and method are described. L. W. G.

Segmentation of the ova of Rhabditis pellio (nuclear-plasmic relations and synthesis of thymonucleic acid). Alberto Stefanelli. *Boll. soc. ital. biol. sper.* **14**, 519–20 (1939).—In 8 generations the nuclear-plasmic relation was const. Synthesis of thymonucleic acid accompanied increased segmentation. Helen Lee Gruehl

Preserving insect specimens and preparing material for display. Richard L. Post. *Ann. Rept. Entomol. Soc. Ontario* **69**, 115–19(1938).—Chem. methods for the treatment and preservation of insect specimens are described in detail. K. D. Jacob

Studies on oxyuriasis. XXI. The chemistry of the membranes of the pinworm [Enterobius vermicularis] egg. Leon Jacobs and Myrna F. Jones. *Proc. Helminthol. Soc. Wash., D. C.* **6**, 57–60(1939).—Attempts to establish the nature of the protein composing the outermost membrane of the pinworm egg were unsuccessful. The shell proper is composed of chitin and the innermost membrane is a sterol. It appears that an effective *ovicide* must contain substances that will dissolve proteins and lipoids in order to reach the embryo. Cf. *C. A.* **32**, 7572[9]. K. D. J.

The fertilizing substance in Arbacia pustulosa. I. M. Hartmann and O. Schartau. *Biol. Zentr.* **59**, 571–87 (1939).—The secretion fluid of the eggs contains an agglutinating and an activating principle for the sperm. The activation effect is destroyed by light; heating to 95° destroys the agglutinating principle only. The activating substance is Echinochrome A, which belongs to the group of naphthoquinone dyes. The limit of its biol. activity is 1:2,500,000,000. Various other artificial or vegetable dyes proved to have similar activity although higher concn. was necessary. A. E. Meyer

The eye pigment of Ephestia kühniella and its comparison with the eye pigments of other insects. Erich Becker. *Biol. Zentr.* **59**, 597–627(1939).—Methods of extn. and chem. reaction of the pigments in the eyes of insects are described. The pigments are divided into 2 groups, the high-mol. dark-red or brown "Ommins," which are related to melanin, and the "Ommatins," which are probably chromoproteins. A. E. Meyer

The behavior of the melanophores of hypophysectomized Selachii and Amphibia after administration of corticotropic hormone. Paul Dittus. *Biol. Zentr.* **59**, 627–52(1939).—Corticotropic hormone of the anterior pituitary was tested for absence of direct melanophore action on interrenal-ectomized Selachii and also for absence of thyrotropic hormone. The substance causes in the hypophysectomized animals increase of depth and frequency of respiration and expansion of the melanophores. This reaction permits the detection of minute quantities of corticotropic hormone. *Amblystoma mexicanum* may also be used as a test animal. A. E. Meyer

Chemical study of Fugu (Spheroides rubripes) poison. I. Nitrogen distribution in the purified poison. Zyunzi Nagai and Takaaki Ito. *J. Biochem.* (Japan) **30**, 235–8 (1939).—The ovary of the Fugu fish contains a strong poison. Fresh ovaries are rubbed up and extd. with 10 vols. of H_2O on a boiling water bath for 2 hrs. The ext. is dialyzed, then evapd. to $^1/_5$ its vol. under low pressure. Impurities are removed by successive pptn. with $HgSO_4$, phosphotungstic acid and $AgNO_3$, and the excess metal is removed (H_2S, hot satd. baryta). The brownish hygroscopic residue is very active. The isolation of the poison in cryst. state was not successful. The total N of the purified poison equals the amino N. On heating in an alk. medium 30% of the N is liberated as NH_3. The poison gives a pos. ninhydrin but neg. biuret, Millon or Sakaguchi reaction; it does not give off N with hypobromide; it does not give any color with $FeCl_3$, H_2SO_4 or HNO_3; it decolorizes warm $KMnO_4$ but not Br_2. It does not yield acylated derivs., is not pptd. by salts of heavy metals, Reinecke's salts, or by flavianic, picrolonic, rhodanilic and rufianic acids; it is not adsorbed by permutite, alumina, kaolin, etc. S. Morgulis

Studies on growth of the silkworm. Different synthetic and catalytic elements and their biological significance during growth. Akira Akao. *J. Biochem.* (Japan) **30**, 303–49(1939).—A very extensive study of the changes in

dry substance, ash, C, H, Na, K, Ca, Mg, Fe, Zn, Mn and Cu during the entire life span of the silkworm. The newly formed caterpillar contains much Zn, Fe and Cu during its entire growth period and little ash, Na, K, Ca or Mn. The behavior of Mg is rather unique in that it is highest in the early stages and reaches a high peak again during pupation. The distribution of the various ash components was also followed in the caterpillar, pupa, cocoon and egg. The cast-off skins and cocoons had a particularly high Ca content. Of the catalytically important elements, Zn was concd. in localities of great vital activity, as in the silk glands, egg stalk, hemolymph, etc., whereas the shed skin or cocoon contained very little Zn. On the other hand, Mn was concd. in the skin and cocoon while little was present in the embryo or hemolymph. This leads to the belief that Zn and Mn play entirely different roles as catalysts in the metamorphosis of the silkworm. The 4 important catalytic elements are present in the silkworm in the following quant. relationship: Zn > Fe > Mn, Cu. S. Morgulis

The inorganic composition of the body fluids of three marine invertebrates. James D. Robertson. *J. Exptl. Biol.* **16**, 387–97(1939).—The body fluids of *Echinus esculentus* and of 2 decapod crustaceans, *Homarus vulgaris* and *Cancer pagurus*, were analyzed before and after dialysis with sea water in which they were living. The compn. of the perivisceral fluid of *Echinus* is identical with that of sea water, complete physicochem. equil. existing between the 2 fluids. The blood plasmas of *Homarus* and *Cancer* are in dynamic equil. with sea water. They contain more Na, K and Ca and less Cl, Mg and sulfate than sea water. The antennary gland fluid of *Cancer* contains less Na, K, Ca and Cl and more Mg and sulfate than the blood plasma. The antennary glands and the surface membranes are important factors in regulating the inorg. compn. of the blood. Benjamin Prescott

The relation between the electrolytic solution pressures of the metals and their toxicity to the stickleback (Gasterosteus aculeatus L.). J. R. Ericksen Jones. *J. Exptl. Biol.* **16**, 425–37(1939).—Lethal concn. limits were detd. for the H^+ and the ions of 18 metals on the stickleback. The lethal concn. limits formed and based on a mg./l. basis were in the following order of increasing toxicity: Sr, Ca, Na, Ba, Mg, K, Mn, Co, Cr, Ni, Au, Zn, Cd, Pb, Al, Cu, H, Hg, Ag. All the ions with the exception of the metals of the alkalies and alk. earths bring about death of fish by pptg. the gill secretions, causing asphyxiation. The alkali and alk. earth metals appear to enter the body and act as true internal poisons. The position of Fe is uncertain. On a mg./l. or molar concn. basis there is a marked relationship between toxicity of the metals and their soln. pressures. The metals of low soln. pressures (Ag and Cu) are the most toxic while those with higher soln. pressures act more slowly. Benjamin Prescott

Observations on the blood of certain ascidians, with special reference to the biochemistry of vanadium. D. A. Webb. *J. Exptl. Biol.* **16**, 499–523(1939).—The bloods of a no. of species of Ascidiacea were examd. with reference to the presence of a V chromogen. The chromogen is always contained, together with H_2SO_4, in a special type of cell called vanadocyte. Exptl. evidence and theoretical considerations show that the V chromogen is not a respiratory pigment. No function can be ascribed to it. It is not a protein or porphyrin compd. but seems to consist of V in assocn. with a straight-chain complex of pyrrole rings, comparable to a bile pigment. Benjamin Prescott

Spawning induced prematurely in the trout with the aid of pituitary glands of the carp. Arthur D. Hasler, Roland K. Meyer and Howard M. Field. *Endocrinology* **25**, 978–83(1939).—Both mature eggs and sperm were obtained from rainbow trout 6–7 weeks in advance of the onset of the normal spawning period in Wisconsin by intraperitoneal injections of fresh or Me_2CO-dried pituitary glands of the carp. Pregnant mare serum and the follicle-stimulating fraction prepd. from sheep pituitary failed to induce spawning prematurely. Felix Saunders

1 **Effect of the crustacean eye-stalk hormone on water metabolism and melanophore expansion in the frog.** Stephen W. Gray and Walter Ford. *Endocrinology* **26**, 160–2(1940).—The crustacean eye-stalk hormone (ESH) is present in a fresh-water form (*Cambarus blandingii acutus*) as well as in a marine form (*Uca pugilator*). ESH from both marine and fresh water crustaceans has an effect similar to that of pitressin and vertebrate pituitaries on
2 frog melanophores, and on frog water uptake. Felix Saunders

The quality of blood catalase in warm-blooded and cold-blooded animals. A. V. Blagoveshchenskiĭ and A. V. Vadova. *Bull. biol. méd. exptl. U. R. S. S.* **3**, 415–18 (1937)(in English).—The authors measured blood-catalase activity at 0° and 10°, computed $K = l/t \ln a/(a - x)$, and $E_a = 1.986 \ln K_{10}/K_0 . T_1 . T_2/(T_2 - T_1)$. The values found for E_a were: dog, 2,200; dingo, 2,700;
3 cat, 5,000; bear, 7,000; hedgehog, 4,500; *Macacus mulattus* Shaw, 13,100; *Macacus memestrinus*, 12,600; pheasant, 5,200; quail, 4,700; sparrow, 3,200; guinea pig, 6,300; rabbit, 10,200; hamadril, 16,500; Armenian viper, 17,050. In most cold-blooded animals blood catalase was destroyed at 10°. The E_a values are low in young animals. Walter H. Seegers

Supplementary report on the causative agent of polyhedral disease of silkworm. M. Hosokawa and K. Kyo.
4 *J. Chosen Med. Assoc.* **29**, 1921–4 (English abstr. 124–5) (1939).—A virus was isolated which produced polyhedral disease in 224 of 295 worms in 3–6 days after the inoculation. The worms first treated with the virus heated 1 hr. at 60° are sometimes slow in development of the disease, or sometimes are completely immunized. By means of Hosokawa's eosin-Giemsa stain, this causative virus can be identified in the subcutaneous fatty tissues of the
5 diseased worms. S. Tashiro

Blood chemistry of fish. II. Blood-sugar contents of fresh-water fishes in different seasons. S. K. Gon. *J. Chosen Med. Assoc.* **29**, 1925–30(English abstr. 125) (1939); cf. *C. A.* **33**, 244[8].—The blood-sugar contents of eel (*Astroconger myriaster*), carp (*Cyprinus carpio* L.) and kamulchi (*Acanthogobius hasta*) are, resp., in mg. per 100 cc.: in spring 141, 149, 120; in summer 44, 132, 95; in autumn 80, 98, 86 and in winter 130, 256 and 86.

Organoleptic characters in bromatological chemistry. Cordélia Nobrega Duarte and Paulo Guimarães da Fonseca. *Arquiv. hig. saúde pública* (São Paulo) **4**, No. 6, 49–55 (1939).—Didactic. O. W. Willcox

The problem of mixed breads. Mario Sampaio Melo. *Arquiv. hig. saúde pública* (São Paulo) **4**, No. 6, 31–45 (1939).—Wheat flours (analyses given) from 17 sources were used in baking tests with addns. of cassava flour (I), corn starch (II) and rice starch (III) in various proportions singly and together. Bread made from wheat flour and I was satisfactory in every respect up to a content of 12% of I. Increase of I to 15% induced a slight change of flavor that was perceptible to fastidious persons, but for the kilo-loaf trade among the working classes increasing the proportion of I to 30 or 40% evoked no complaints. Addns. of II were optimum up to 8% and good up to 12%; beyond that the flavor disqualified the bread for fastidious consumers but the kilo-loaf trade made no objection to 25%. Addns. of III were good up to 10%; beyond that panification was difficult. Breads made from 70% of wheat flour and 10% each of I, II and III were satisfactory in all respects. The loaves in all outward aspects were similar to bread from 100% wheat flour and the flavor was not affected by the combined addns. O. W. Willcox

The use of sodium metaphosphate for the preparation of soft-curd milk. Charles Schwartz, K. K. Jones, T. W. Mack and R. W. Vance. *J. Dairy Sci.* **23**, 19–35 (1940).—Na metaphosphate when added to milk in an av. ratio of approx. 41 mg. to 100 ml. prevents the formation of a curd when the milk is treated with a pepsin-HCl coagulant. For the milk samples used the metaphosphate required to prevent curd formation varied from 30 to 52 mg. per 100 ml. of milk. When metaphosphate is added to milk before heating, the amt. should be increased to 75 mg. per 100 ml. of milk. Addnl. Ca can be added to milk and zero curd tension can be obtained by adding metaphosphate. Expts. *in vitro* indicate that metaphosphate-treated milk is more easily digested than untreated milk. Na metaphosphate is nontoxic in the doses used. When added to milk it seems to form a sol. complex with Ca that may be absorbed and utilized by the body. The addn. of Na metaphosphate to a diet decreases Ca excreted in the feces and increases the Ca excreted in the urine. Na metaphosphate increases the Fe absorption from an Fe-contg. milk diet. Na metaphosphate appears to be a safe, simple and economical means of prepg. soft-curd milk either in the home or in the dairy. In contrast to the other methods available this treatment requires no addnl. equipment and very little addnl. labor. A. H. Johnson

Detecting mustard gas in potable water or milk. A. Tasman. *Chem. Weekblad* **36**, 786(1939).—A method devised by the Dutch Artillery Lab. at Delft is described: The sample is shaken with a certain prepd. charcoal, filtered and dried. The charcoal grains are then subjected to the known reactions, e. g., the hepar and $AuCl_3$ reactions. A. H. Krappe

Crude milk sugar and poultry feed suitable outlets for milk solids in whey. W. E. Stringer. *Food Ind.* **11**, 72–4(1939); cf. *C. A.* **33**, 9464[9].—Flow sheets for manuf. of these products are given. Whey yields 2.75% crude lactose and 3.25 poultry feed including 1% albumin. C. R. Fellers

Laboratories approved for the phosphatase test. F. W. Gilcreas. *Health News, N. Y. State Dept. Health* **15**, No. 32, 134(1938); *U. S. Pub. Health Eng. Abstracts* **19**, Mi, 8 (Mar. 11, 1939); cf. *C. A.* **33**, 8322[5].—Continued experience with the phosphatase test has proved it to be an invaluable aid in controlling the *pasteurization of milk*. Coöperative tests with 14 different labs. showed an excellent agreement of results. A precision greater than 97% was found in the use of the test. Cf. *C. A.* **33**, 2598[8]. C. R. Fellers

The surface and center of butter stored in kegs. W. Mohr and E. Schrimpl. *Molkerei-Ztg.* (Hildesheim) **53**, 1212–13(1939).—Butter was stored in kegs for 6 months at −20°, thawed 3 days and kept for 13 days at 15–16°. Butter from the surface was markedly inferior in flavor to butter from the center, but chem. and phys. tests indicated very little or no difference between the samples. Wrapping butter in air- and water-impermeable paper before storage decreased surface deterioration. E. C.

The bacterial flora of New Zealand Cheddar cheese. I. R. Sherwood. *J. Dairy Research* **10**, 426–48(1939).—Of the lactic acid bacteria isolated, 720 strains from 36 typical Cheddar cheeses were classified. The dominant organism in New Zealand cheese was shown to be *Streptobacterium plantarum*. *Sbm. casei* occurs much less frequently while betabacteria and betacocci are found in still smaller nos. Betabacteria tend to replace *Sbm. plantarum* in the final stages of cheese ripening. The flora of good-quality cheese consists mainly of 1 or 2 varieties of *Sbm. plantarum*, often assocd. with *Sbm. casei* or a small proportion of betabacteria. In poor-quality cheese a larger no. of types of lactic acid bacteria frequently occur. A simple routine method is described for distinguishing different groups present in cheese. The effects which different strains of lactobacilli and betacocci produce in cheese were correlated with their biochem. characteristics. *Sbm. casei* in general appears to be beneficial to cheese quality. The strains of *Sbm. plantarum* isolated have been grouped in 4 varieties, mainly on the basis of sugar reactions. One variety was shown to be beneficial to cheese quality, another variety had little apparent effect, while the remaining varieties produce serious defects—bad flavors, discoloration and occasionally open texture. The same defects were produced by most strains of betabacteria and betacocci when present in large nos. The biochem. characteristics of the lactobacilli studied showed a regular graduation from *Sbm. casei* through *Sbm. plantarum* to *Betabacterium breve* that is indicated from the generally accepted system of classification. A. H. J.

Bacterial contamination of "brynza" (cheese made from sheep's milk), methods for rendering it harmless for consumption and indexes for its evaluation. I. P. Vizir, L. Garkavi and R. Rutman. *Mikrobiol. Zhur.* **5**, No. 4, 65–76(1938).—The frequent bacterial contamination of cheese and the observed cases of poisoning (mainly intestinal microbes *Proteus vulg.* and *B. coli*) made it necessary to find methods for a general evaluation of the suitability of the product. The following are recommended: the degree of acidity should not be below 200° T., which may be taken as an index of the aging of the cheese; the *Es. coli* titer should not exceed 0.01 g.; and the concn. of salt in the finished cheese should not be below 5% to insure its keeping qualities. **II. Dynamics of the bacterial and of the physical-chemical processes.** P. Vizir and L. Garkavi. *Ibid.* 77.—The dynamics of the bacterial and the physical-chem. processes in the aging of "brynza" prepd. from raw and from pasteurized milk, from milk to which *Streptococcus lactis* has been added, and from milk contaminated with *Proteus vulg.* and *B. breslau* were investigated. The bacterial contamination of the cheese can be in most cases explained by the primitive methods employed in the production of "brynza." Pasteurization increases considerably the time of aging of the cheese, but does not interfere with the fermentation process. The slowly increasing acidity (the main bactericidal factor), which does not reach a high degree, leads to an increased bacterial contamination. The use of enzymes made from sour milk microbes accelerates the aging of "brynza." Through *Khim. Referat. Zhur.* **2**, No. 4, 70(1939). W. R. H.

Processing and thiamine. Aaron Arnold and C. A. Elvehjem. *Food Research* **4**, 547–53(1939).—The thia-

mine content of beef kidney, beef spleen and beef-lung tissue was decreased by 70–80% during a thermal treatment of 120 min. at 115.6°. In a moist meat product-grain mixt. the greatest loss occurred during the 1st hr. of heat-treatment. Hog muscle lost over 80% thiamine during a heat-treatment of 110 min. at 121°. C. R. F.

Studies on the bacterial flora of North Pacific salmon. Jane E. Snow and Paul J. Beard. *Food Research* **4**, 563–85(1939).—The most commonly occurring genera are *Achromobacter, Micrococcus, Pseudomonas, Kurthia, Flavobacterium* and *Proteus*. Of the various biochem. tests used as spoilage indexes for salmon, H_2S shows most promise. Indole is rejected as inadequate as an index of decompn. It is suggested that several types of bacterial activity be used to judge the extent of decompn. in salmon rather than a single index. Cf. *C. A.* **21**, 463. C. R. Fellers

Studies in fish spoilage. VI. Breakdown of carbohydrates, proteins and amino acids during spoilage of cod muscle press juice. S. A. Beatty and V. K. Collins. *J Fisheries Research Board Can.* **4**, 412–23(1939); cf. *C. A.* **33**, 5441[2].—After the early postmortem changes, such as breakdown of glycogen and phosphocreatine and the formation of traumatic NH_3, autolysis of cod fish muscle press juice that is contaminated by spoilage bacteria is negligible in proportion to the action of bacteria. Samples of the press juice were (1) preserved with toluene, (2) kept in stoppered bottles with very small amts. of air and (3) exposed to the air, at 0.5°, 5° and 25°. The decrease in amt. of lactic acid, sugar and the amino acids was measured, as well as the production of trimethylamine, CO_2 and NH_3. Juice passed through a Seitz E. K. filter acted like (1) with little oxidation of lactic acid, sugar or the amino acids. Juices treated in (2) and (3) showed surprisingly slight differences, showing that, during early spoilage, the bacterial growth is both anaerobic and aerobic, the actual oxidation of the substrate being mainly anaerobic. Later when the press juice is definitely spoiled, aerobic oxidation assumes the major part if air is available. Spoilage occurs in 2 stages irrespective of the availability of air: first the oxidation of lactic acid and sugar, and, secondly after these reactions are well under way, the oxidation of the amino acids and the hydrolysis of proteins. The second stage represents advanced spoilage. As $(CH_3)_3N$ production occurs mainly during the first stage, it is a good criterion as to the probable production of toxic compds. resulting from protein and amino acid breakdown. Dorothy A. Meyer

Some data on the nutritive value of the banana. Celina Fonseca. *Arquiv. hig. saúde pública* (São Paulo) **4**, No. 6, 59–62(1939).—New analyses of the maca and nanica varieties show dry substance 35.12–30.67, proteins 1.05–1.13, glucose 17.96–16.53, sucrose 2.03–2.41, ash 0.78–0.55, acidity as H_2SO_4 0.35–0.18%. The presence of small amts. of succinic, malic and tartaric acids is noted. Vitamins B and C are present. O. W. Willcox

Fruit-juice standarization. Christopher P. Norbury. *Ann. Rept. Agr. Hort. Research Sta., Long Ashton, Bristol* **1938**, 226–30(Pub. 1939).—Fruit-juice standards in various countries are briefly discussed. K. D. Jacob

A comparative investigation of different methods for the determination of fruit acids. N. V. Saburov, M. I. Kalebin, L. P. Khakhina and A. Danilova. *Nauch. Zapiski Inst. Narodnogo Khoz. im. Plekhanova* **1938**, No. 1, 3–50; *Khim. Referat. Zhur.* **2**, No. 4, 82(1939).—The method of Hartmann and Hillig (*C. A.* **24**, 2209), in which the org. acid is preliminarily pptd. in the form of Pb salts, gave best results in the detn. of tartaric acid in the presence of citric and malic acids, but is awkward because it requires the use of a centrifugal app. and of H_2S. The method of Täufel and Marloth (*C. A.* **24**, 2966) can be used only if the amt. of tartaric acid is less than 0.3%. Good results were obtained by a modification of the method of Muttelet (*C. A.* **16**, 3142), in which the org. acids are sepd. preliminarily in the form of Ba salts. The method of Kometiani (*C. A.* **26**, 669) for the detn. of citric acid in the presence of malic and tartaric acids by transforming the citric acid into pentabromoacetone is not suitable. Good results were obtained (in fruit juices as well) by the method of Hartmann and Hillig (*C. A.* **21**, 2451), which is based on an analogous oxidation. It can be simplified by replacing the gravimetric detn. of pentabromoacetone by the volumetric detn. The method of Kogan (*C. A.* **24**, 2692) based on the oxidation of citric acid to acetonedicarboxylic acid with the detn. of the latter in the form of acetone is inaccurate. When modified the method becomes more accurate, but is tedious. The detn. of $H_2C_2O_4$ in the presence of tartaric, citric and malic acids by the method of Bau (*C. A.* **12**, 2037) (pptn. as CaC_2O_4 in a H_3PO_4 soln.) gives more accurate results than the method of Butkevich (which is also based on the smaller soly. of CaC_2O_4 in the detn. of the acidity of the soln. as compared with the soly. of the Ca salts). Although the method of Butkevich is faster for single analyses, the method of Bau requires less time in case of mass analyses. In the analyses of fruit juices by means of these methods pectin must be preliminarily pptd. The polarimetric and the permanganate methods of Hartmann and Hillig (*C. A.* **27**, 146) gave the best results in the detn. of malic acid in the presence of tartaric and citric acids, but they required the use of a centrifugal app. and of H_2S. The method of Auerbach and Krüger (*C. A.* **18**, 511, 868), in which the org. acids are sepd. in the form of the Ba salts, is simpler. W. R. H.

Micromethods for the determination of sugars, of nitrogen and of amino acids in fruits and vegetables. N. V. Saburov, L. V. Kaperina, P. V. Sokolov and R. S. Shcherbakov. *Nauch. Zapiski Inst. Narodnogo Khoz. im. Plekhanova* **1938**, No. 1, 51–75; *Khim. Referat. Zhur.* **2**, No. 4, 83(1939).—The iodometric method of Tompsett (*C. A.* **25**, 309) was found to be the best of the 6 investigated methods. The iodometric method of Shaffer and Hartmann (*C. A.* **11**, 1327) is less accurate, but simpler. The ferricyanide method of Ionescu (*Z. Untersuch. Lebensm.* **62**, 363(1921)) is rapid, but requires some skill and is less accurate. The permanganate method of Bierry and Goiren (cf. *C. A.* **22**, 3675, 3676) is accurate, but awkward and is more suitable for single detns. than for many simultaneous analyses. When a less accurate method is required a combination of Bierry-Goiren's and Tompsett's methods can be used. The manganometric method of Fontès and Thivolle (*C. A.* **21**, 2712) is not recommended. N can be detd. in fruits and vegetables by the micro-Kjeldahl method. If the products give a heterogeneous mass after grinding, the combination micro- and macro-Kjeldahl method is recommended. In detns. of small amts. of the amino N in fruits and vegetables without concg. the exts. the micro-app. of Van Slyke is not very suitable. The macro app., in which the usual gas buret is replaced by a microburet, gives good results. Amino N in amts. to 1.5 mg. can be detd. in this app. with an av. accuracy of 0.01 mg. W. R. Henn

Standards of identity, fill of container, and quality and label statements for canned peaches. *Federal Register* **4**, 4920–4(1939).—Regulations under the Federal Food, Drug, and Cosmetic Act provide a standard of fill of container and a definition and standard for canned peaches as mature yellow or white, cling or freestone varieties packed in water, peach juice or light, medium-heavy or extra-heavy sirups (made with sucrose with or without dextrose) in the forms of whole, half (peeled and unpeeled), peeled slices, diced, or mixed pieces of irregular sizes and shapes. The variety, form and packing medium must be stated on the label as well as the other optional ingredients, spice, flavoring, vinegar, peach pits or kernels. The standard of quality includes the factors of tenderness, size, uniformity of size and shape of units, absence of peel (except unpeeled forms), freedom from blemishes, and from crushed or broken units. A method is detailed for detg. tenderness. Statements are provided for labeling peaches substandard in fill of container or in quality explaining wherein the product falls below the standard. H. A. L.

Standards of identity, fill of container and quality and label statements for canned apricots. *Federal Register* **5**, 93–8(1940).—Regulations under the Federal Food, Drug, and Cosmetic Act for standards of identity, fill of container and quality for canned apricots and labeling requirements

are practically analogous to those for canned peaches (cf. preceding abstr.). H. A. Lepper

Standards of identity, fill of container and quality and label statements for canned pears. *Federal Register* 5, 102–7(1940).—Regulations under the Federal Food, Drug, and Cosmetic Act for standards of identity, fill of container and quality for canned pears and labeling requirements are practically analogous to those for canned peaches (cf. 2nd preceding abstr.). H. A. Lepper

Standards of identity, fill of container and quality and label statements for canned cherries. *Federal Register* 5, 98–102(1940).—Regulations and labeling requirements under the Federal Food, Drug, and Cosmetic Act for standards for canned cherries are analogous in principle to those for canned peaches (cf. 3rd preceding abstr.). The standard provides for red sour, light-colored sweet and dark-colored sweet varieties, pitted and unpitted. Quality factors are freedom from blemishes and from pits in pitted cherries, min. size and uniformity of size of units and percentage of cherry flesh in unpitted cherries. Specific directions for detg. pits and percentage of cherry flesh are included. H. A. Lepper

The vitamin C content of German apple varieties and its dependence on habitat, light intensity, fertilizing, density of fruit hanging and storage. Wolfgang Kessler. *Gartenbauwiss.* 13, 619–38(1939).—The ascorbic acid content of several varieties of apples, exclusive of peel, was detd. by the Fujita and Ebihara adaptation of the Tilmans method (cf. *C. A.* 31, 5399[4,9]). Certain modifications were made. The vitamin C varied in the different varieties from 0.3 mg./100 g. for the Rote Stern Renette to 23.4 mg./100 g. for the Ontario. For a given variety, those from southern Germany were, in general, a richer source of the vitamin than the northern apples. Fruit, which had ripened unevenly because of shading, showed 30–50% more ascorbic acid on the red side. This was not attributed to an assocn. with the red pigment but to the light intensity; the latter increased the vitamin content. Naturally light-colored apples were often richer in ascorbic acid than the dark-red varieties. Fruit from trees which were heavily loaded were poorer in vitamin C than fruit from trees less densely populated. The overfertilizing of trees with N depressed the ascorbic acid content of the fruit. The storage of apples at temps. below 5° for 5 months resulted in very little loss of vitamin C. C. K. Horner

Factors affecting adsorptive power of magnesia for carotene. G. S. Fraps, A. R. Kemmerer and S. M. Greenberg. *Ind. Eng. Chem., Anal. Ed.* 12, 16–18(1940).—The adsorptive powers of Mg compds. were studied to secure prepns. which adsorb xanthophyll and do not adsorb carotene, and thus could be used in the purification of the solns. of carotene in petroleum ether obtained in detns. of vitamin A potency of foods. Nineteen samples of MgO and $Mg(OH)_2$ from various sources were tested as received and after activation by heating with an equal vol. of water for 30 min. on a steam bath. All adsorbed carotene, and so could not be used for purifying carotene solns. Activated Mg heated in a muffle furnace at 400° and then reactivated adsorbed 76% of the carotene, 25% at 750° and 0.5% at 900°. When 14 other samples were heated to 900° and activated, 7 had adsorptive powers for carotene lower than before heating, 2 had the same, and 5 had higher powers. The adsorptive powers were lowered as the Mg compds. were mixed with increasing amts. of water, until they became zero for the samples tested. Exposing Mg compds. to CO_2 or air lowered the adsorptive powers of activated Mg for carotene. All samples of activated Mg which did not adsorb carotene when freshly prepd. did so after about a week. However, some samples of $MgCO_3$ did not adsorb carotene when purchased, while others required activation. Activated $MgCO_3$ seems to be more stable than activated MgO or $Mg(OH)_2$. The adsorptive power of the reagent for carotene and for xanthophyll should be measured before it is used. D. A. Meyer

Vitamin C content of vegetables. XII. Broccoli, cauliflower, endive, cantaloup, parsnips, New Zealand spinach, kohlrabi, lettuce and kale. Katherine Wheeler, Donald K. Tressler and C. G. King. *Food Research* 4, 593–604(1939); cf. *C. A.* 30, 3030[6].—The indophenol titration technique for ascorbic acid detn. gave results in concord with the usual guinea-pig assay for vitamin C for all these vegetables. The approx. av. ascorbic content expressed as mg. per g. of edible portion of the freshly harvested vegetables is: parsley 2.0, broccoli 1.3, kale 1.3, cauliflower 0.9, kohlrabi 0.65, New Zealand spinach 0.45, cantaloup 0.35, lettuce 0.16 and endive 0.14. The leafy vegetables and cauliflower and broccoli lost their ascorbic acid rapidly after harvesting unless promptly refrigerated. Parsnips lost much of their ascorbic acid during winter storage. C. R. Fellers

Vitamin values of garden-type peas preserved by frozen-pack method. II. Vitamin A. E. N. Todhunter. *Food Research* 4, 587–92(1939); cf. *C. A.* 33, 7915[9].—Quick-frozen peas contained 10 intern. units of vitamin A per g. Controls on fresh peas were not made. The blanching (scalding) period did not affect the vitamin A content. Varietal differences were slight. Cooking by boiling had no effect on the vitamin A content of frozen peas. III. Thiamine (vitamin B_1). Margaret L. Fincke. *Ibid.* 605–11.—Frozen peas contained 2–4 γ of thiamine per g. A 2-min. blanching period at 71° conserved the thiamine better than longer blanching periods. Hot water and steam blanching gave the same results. C. R. Fellers

A proteolytic enzyme of lima beans (Phaseolus lunatus L.). Ward B. Davis. *Food Research* 4, 613–19(1939).—A proteinase of the papain type was found in Fordhook variety of lima beans. The enzyme was demonstrated by its digestion of casein and its liquefaction of gelatin. The enzyme is easily destroyed by the heat employed in the blanching process incident to freezing or canning lima beans. It is not believed that the proteinase is of significance in quick-frozen lima beans held in storage. C. R. Fellers

Sugar content and keeping quality of the cooking onion. Alfred Zeller. *Gartenbauwiss.* 13, 598–604(1939); cf. *C. A.* 33, 5888[8].—Statistical analyses of results, including those of other investigators, confirmed the reports that the keeping quality of the onion is assocd. with a higher sugar (especially sucrose) content. Proposed means of obtaining better onions are: harvesting at a detd. time shortly before complete ripening, culturing on a loose sandy soil and storing at higher temps. (smoking, drying). C. K. Horner

Vegetable juices of standardized flavor. John B. Rolle. *Food Ind.* 11, 75, 113–14(1939).—The freshly chopped or crushed vegetables are extd. for 24 hrs. at 60°F. in tightly closed stoneware containers with a predetd. quantity of condensate. This gives a juice of standardized essential oil or essence strength. Manufg. methods are detailed. C. R. Fellers

Honey containing vitamin C. C. Griebel and G. Hess. *Z. Untersuch. Lebensm.* 78, 308–14(1939).—The identity of the strong reducing substance in thyme and mint honey with ascorbic acid was proved by converting it into the dehydro form and causing it to react with 2,4-dinitrophenolhydrazine (cf. Ammon, *et al.*, *C. A.* 31, 727[4], 747[2]). Since the dehydro form of ascorbic acid contains 2 carbonyl groups which react with phenylhydrazine the authors preferred naming the condensation product a dihydrazone instead of an osazone. The 2,4-dinitrophenoldehydroascorbic acid dihydrazone obtained in the honey analysis m. 266°. This checks the prepn. from synthetic ascorbic acid. Buckwheat honey contains traces of ascorbic acid. A titrometric I method for the detn. of ascorbic acid in honey is presented. M. M. Piskur

Honey and the lead contamination problem. H. A. Schuette and A. J. Ihde. *Food Research* 4, 555–62(1939). -Pb is not a normal constituent of honey. The source of Pb in honey is from Pb arsenate sprays. Extg. app. also contaminates extd. honey. Eighty-three % of the honey samples examd. were substantially free from Pb. Only 1 sample contained as much as 6.8 p. p. m. C. R. F.

Guavas and guava jellies. C. C. Guimaraes and Maria de Abreu. *Arquiv. hig. saúde pública* (São Paulo) 4, No. 6, 75–9(1939).—The proximate compns. of various varieties

are given. The presence of vitamins B and C in guava jelly is verified. Certain adulterants are detectable because pure guava jelly contains no starch nor citric acid. O. W. Willcox

How fumigation affects popping quality of corn. H. D. Young, R. T. Cotton and G. B. Wagner. *Food Ind.* 11, 14, 56(1939).—HCN, CS_2, C_2H_4O, chloropicrin and CCl_4 adversely affect the popping ability of popcorn for 10–20 days. In most cases, however, this injurious effect disappears after 30 days. C. R. Fellers

The method of quantitative estimation of the aroma of scented tea. Kenzi Ueno. *J. Agr. Chem. Soc. Japan* 15, 1013–17(1939).—The aroma of tea scented with the flower of navel orange was approx. estd. by the degree of the odor or the amt. of indole. Y. Kihara

Cytochrome oxidase in tea fermentation. J. Lamb and E. A. Houghton Roberts. *Nature* 144, 867–8(1939); cf. *C. A.* 33, 7917[8].—Evidence is given that the oxidase responsible for the oxidation of ascorbic acid in the tea leaf may be identified with cytochrome oxidase, and that it is unlikely that an ascorbic acid oxidase is present. E. D. Walter

Solvent powers of organic liquids on flavoring materials. J. G. Davidson. *Glass Packer* 17, 783–5(1938).—An ideal solvent for flavoring substances should impart no odor or taste to the final flavored product, it should be nontoxic in the max. concns. that can be reasonably used, it should be H_2O-sol. and inexpensive. There is at present no good substitute for EtOH. Data on relative toxicities of many of the proposed solvents are incomplete. Soly. data for common org. solvents are given in graph form. C. R. Fellers

Ensile experiments with and without addition of whey and of mineral acid and sugar. V. J. C. de Ruyter de Wildt. *Verslag. Landb. Onderzoek.* No. 45, C, (9), 207–54 (1939)(Summary in German, 249–54); cf. *C. A.* 33, 1406[6].—Pure cane sugar and "Biosil" acid were used. It was found that withered grass needed much less acid than fresh grass. With withered grass and the addn. of acid only, the same results were obtained as the addn. of the double amt. of acid per kg. dry substance plus a little more than 1% sugar to fresh grass. An excellent silage was obtained by the addn. of 3% sugar to fall grass, contg. about 16% crude albumin in the dry substance, with small ensile losses, and no butyric acid. With 2% sugar in a closed concrete silo a good lactic acid silage was produced, which contains 1.82% lactic acid, 0.15% butyric acid at a pH of 3.97; here, however, only $^2/_3$ of the silage was submerged in the juice. By using 10% whey and 1% extra sugar in an open silo poor results were obtained. J. C. J.

Measurement of coagulation [of milk] (Wannow) 2. Making a lacquer for tin cans [for food] (Rubinskiĭ) 26. Detn. of CO_2 in baking powders, self-rising flours (Hepburn) 7. Purification and disposal of milk wastes (Hepburn) 14. Phosphate esters [for preparing chocolate mixts. for coating cakes] (U. S. pat. 2,177,983) 13. Malt-like sirups for baking processes (U. S. pat. 2,179,203) 16. Preventing caking of hygroscopic materials [dry liver concentrate, dried meat ext.] (U. S. pat. 2,175,083) 13.

Kay, H. D., Aschaffenburg, R., and Neave, F. K.: The Phosphatase Test for Control of Efficiency of Pasteurization. Shinfield, England: Imperial Bur. of Dairy Science. 54 pp. $.75.

Apparatus for evaluation of the quality of flour and paste. Erdély és Szabó Tudományos Müszergyár (B. Gy. Bán, inventor). Hung. 121,488, Sept. 15, 1939. The app. is equipped with 2 horizontal axes bearing kneading devices, one of which is operated by an elec. motor. The kneading container can move freely and its movements during kneading are recorded by a suitable measuring device.

Leavened baked products. Jacob Freilich and Charles N. Frey (to Standard Brands Inc.). U. S. 2,178,959, Nov. 7. Leavening (as of various specified doughs and batters) is effected by the conjoint action of yeast and H_2O_2 (suitably in the presence of an alk. material such as $NaHCO_3$ giving the dough mass a pH of 6.5–8.5), the leavening being principally effected by the H_2O_2.

Milk preparation. László Pikler. Hung. 122,066, Nov. 15, 1939. Fresh or condensed milk is mixed with substances (dextrin-maltose, betaine chloride) that ppt. proteins on heating. Ca salts (lactate or hydrolactate) may be added to obtain an infant food.

Apparatus for vacuum and carbon dioxide treatment of eggs or other foods. Charles E. Evans (50% to L. G. Howard). U. S. 2,179,327, Nov. 7. Various structural and operative details suitable for the treatment of eggs, etc., with CO_2 under pressure.

Sugarless gelatin food products. Llewellyn R. Ferguson (to General Foods Corp.). U. S. 2,178,569, Nov. 7. Various details are given of mixts. which may contain gelatin, mono-Na citrate or tartrate or similar salts, etc., with or without saccharin and other flavorings.

Dry pectin compound. Philip B. Myers (to Sardik Inc.). Can. 385,242, Nov. 21, 1939. To render it readily dispersible in water or fruit juices, pectin is treated with a sol. Ni salt in such amt. that the amt. of Ni present will be 0.1–1.0% of the total wt. of the Ni and pectin so combined.

Fumigant for fruit. John D. Maxcy (to Carbide and Carbon Chemicals Ltd.). Can. 385,741, Dec. 19, 1939. A volatile liquid fumigant is essentially composed by vol. of ethylene oxide about 1 and ethylene dichloride about 3 parts; it has a toxic effect of about twice the amt. of ethylene oxide and about 3 times the amt. of ethylene dichloride employed separately.

Refrigerating and preserving vegetables. James A. Thomas (to Esotoo Fumigation Co. Ltd.). U. S. 2,178,675, Nov. 7. Vegetables such as spinach, beets, carrots, asparagus, Brussels sprouts or celery are cooled with ice contg. SO_2 or with water contg. SO_2 from the melting of such ice.

Food product from papaya. Leroy L. Matoush (to Papaya Corp. of America). U. S. 2,178,593, Nov. 7. Papaya fruit and seeds are separately crushed; the fruit juice is extd., the seeds are treated with a weak acid such as citric acid (as by use of lime juice), and the resulting liquor is mixed with the fruit juice. Various details of operation are described.

Drying apparatus for honey. J. Charlemagne Préfontaine. Can. 385,174, Nov. 21, 1939. The honey is poured over a vertical perforated surface while hot air is discharged against the honey.

Stock feeds. Hans Fattinger. U. S. 2,170,713, Aug. 22. Nondusting products are formed by mixing various stock feeds with an emulsion formed by the admixt. of the carbonation sediment from sugar manuf. and molasses or a sirup from beet- or cane-sugar manuf. or "wood sugar."

13—CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

Industrial research in 1939. Advances in the United States and other countries. Wm. A. Hamor. *News Ed. (Am. Chem. Soc.)* 18, 1–13, 49–58(1940). E. J. C.

Strategic mineral supplies in the U.S. S. R. (Russia). G. A. Roush. *Military Engr.* 32, 22–8(1940); cf. *C. A.* 33, 4345[1].—A discussion relating to the following: Mn ore, Pt, asbestos, phosphates, Fe ore, coal, petroleum, potash, Al, Hg, chromite, magnesite, Zn, Cu, Pb and Ni. Production and consumption figures for 16 years through 1937 are tabulated. L. Wilson Greene

Chemicals and coast defense. A. M. Prentiss. *Coast Artillery J.* **82**, 281–301(1939); cf. *C. A.* **33**, 7921[7].—The properties and tactical uses of chem. warfare agents are discussed. L. Wilson Greene

With or without mustard (gas)? Lathrop R. Bullene. *Coast Artillery J.* **82**, 255–8(1939).—Tactical. L. Wilson Greene

Toxicity of chloropicrin. Béla Ritlop. *Orvosi Hetilap* **83**, 1003–5(1939).—Expts. on cats indicate that chloropicrin should be classified as an irritating rather than a lethal war gas. S. S. de Finály

Economics of health in chemical industries. Emery R. Hayhurst. *Chem. Industries* **45**, 518–21(1939). E. H.

Occupational diseases in chemical processes. Emery R. Hayhurst. *Merck Rept.* **48**, No. 2, 4–10(1939). E. H.

Chlor-acne in railway workers. H. Haldin-Davis. *Brit. J. Dermatol. Syphilis* **51**, 380–3(1939).—Acne was observed in 12 workers engaged in making elec. circuits from wires insulated with perchloronaphthalene ("perna"). The condition is common in those engaged in manuf. or handling of this insulating agent indoors. It may be avoided by covering the skin with "rosalex" and washing at the end of the day with Westrosol soap, which is a 2% soln. of trichloroethylene. Marion Horn

Lead poisoning in industry and its prevention. M. R. Mayers and M. M. McMahon. *N. Y. State Dept. Labor, Div. Ind. Hyg., Special Bull.* **195**, 68 pp.(1938); *U. S. Pub. Health Eng. Abstracts* **19**, IHS, 3(Feb. 25, 1939).—A summary. C. R. Fellers

Harmfulness of aluminum dust taken into the lungs. O. Ehrismann. *Z. Hyg. Infektionskrankh.* **122**, 166–70 (1939).—In expts. with rabbits and guinea pigs exposed to Al dust no pathol. injuries were observed. R. Brown

Plants containing rotenone—industrial dermatitis. J. Racouchot. *Arch. maladies profes.* **2**, 149(1939); *Brit. J. Dermatol. Syphilis* **51**, 493.—An important new group of insecticides derived from plants contg. rotenone, and including such substances as derris, is rapidly replacing the arsenicals previously used in France. Workers prepg. these substances developed in 2–3 days a violent dermatitis of the genital region, and also often a rhinitis with anosmia, and irritation of the tongue and lips. Further trouble has been obviated by improving ventilation, providing masks and paying strict attention to personal cleanliness. Marion Horn

Chemurgic plastics. Robert D. McMillen. *Mfrs. Record* **108**, No. 12, 22–3, 54, 60(1939).—An illustrated description of the development, manuf. and uses of plastics made from agricultural raw materials. L. Scheflan

Casein plastics. Geo. H. Brother. *Ind. Eng. Chem.* **32**, 31–3(1940).—The history of the casein plastic industry is traced from the original galalith of the "wet process," through the "dry process" of making rods and sheets, to the present process of making button and buckle blanks from partially hardened plastic. Noteworthy recent com. developments include the discovery of alum as a partial hardener and of hypochlorite soln. as a polish. B. produced a thermoplastic HCHO-hardened casein from acid casein which has not been sufficiently plasticized, however, to use in injection molding. Possible combinations of casein with phenolic or urea thermosetting resins, and problems connected therewith, are discussed. Continued application of x-ray, infrared ray, ultracentrifuge and unimol. film technique to the investigation of protein structure is expected to aid in establishing a sounder basis from which improved protein plastics may result. H. K. Salzberg

Adhesives. Natural glues in the veneer and plywood industry. S. Horwitz. *Wood* **4**, 462–5(1939).—A discussion of the prepn. and com. applications of vegetable and animal glues. Leopold Scheflan

Cellophane. Donald A. Waterfield. *Newark Eng. Notes* **3**, No. 2, 12(1939).—A brief description of films manufd. from regenerated cellulose, cellulose nitrate, cellulose acetate, rubber hydrochloride, proteins, and Al silicate. Leopold Scheflan

The scouring action of soap and the modern sulfonated textile auxiliaries. J. Davidsohn and A. Davidsohn. *Am. Dyestuff Reptr.* **29**, 43–6(1940).—An attempt is made to show that emulsification is not only brought about by hydrolysis, but that it depends on the constitution of the soap compd. The new sulfonated products are reviewed briefly. Thirty-one references. W. H. Boynton

Polish; metal. *Federal Specification* **P-P-556a**, Apr. 4, 1939. **Polish; silver.** *Ibid.* **P-P-571b**, Apr. 4, 1939. Washington: Supt. of Documents, U. S. Govt. Printing Office. 5¢ each. L. Wilson Greene

Superfinish [method of surface polishing]. O. A. Wallace. *S. A. E. Journal* **46**, 69–92T(1940).—Chem. and mech. surface effects of different types of abrasive polishing are described. H. A. Beatty

Effect of water-soluble salts on the electric properties of paper boards. Yu. V. Koritskiĭ. *Vestnik Elektroprom.* **1939**, No. 9, 25–7.—Both Russian and imported paper boards were dried to a const. wt. at 105°, and then placed in atms. of various relative humidities until const. in wt. after which the sp. vol. resistance was tested at 1500 v. d. c. The variation in water-sol. salt content from 0.31 to 0.58% had no practical effect on elec. resistance. Analogous results were obtained when the specimens were dried at 105° and then impregnated with transformer oil. B. Z. K.

Keeping goods dry in transit. R. L. Hockley. *Chem. & Met. Eng.* **46**, 775–6(1939).—Moisture damage to goods in transit is often very large. The interior of metallic containers frequently corrodes owing to variations in humidity from temp. changes. Activated silica gel, in small quantities, will rapidly reduce the moisture content in sealed packages. The activated gel absorbs 45% of its wt. of moisture with no apparent indication of its water content. H. E. Messmore

Fire-resisting, sound-absorbing materials. D. S. Novakhovskaya. *Stroitel. Materialy* **1938**, No. 7, 45–7; *Khim. Referat. Zhur.* **2**, No. 4, 107(1939).—Acoustical "pemzolit" made out of pumice stone with a portland cement, or magnesia cement can be shaped in a hydraulic press under a pressure of from 5 to 10 kg. per sq. cm. Similar products were prepd. from boiler slag, Donets coal and ceramsite with binders of portland cement, white cement and gypsum. Lab. expts. showed that these materials can be used as fire-resisting, sound-absorbing materials. W. R. Henn

Fumigants. I. Reaction products of trichloroethylene and nitric acid. 1. Mitio Kono and Tadasi Sakai. *J. Agr. Chem. Soc. Japan* **15**, 478–82(1939).—When 30 g. of concd. HNO_3 was added to 200 g. of trichloroethylene, drop by drop, and the product was distd. with steam, a light-yellow oil was obtained. It has a strong fumigating action for insects. It was sufficient to use 0.7–1 lb. for 1000 cubic ft. of space. The properties of the product resemble those of chloropicrin. Sp. gr. 1.665 and b. p. 110–70°. It contained chloropicrin, its isomer and methyl amine. Y. Kihara

Value of insecticidal sprays as an antimalarial measure. P. Moreau. *Rev. méd. franç. d'extreme-orient* **16**, No. 3, 264–74(1938); *U. S. Pub. Health Eng. Abstracts* **19**, Ma, 25(July 29, 1939).—An aq. ext. of pyrethrum contg. 5.5% pyrethrins keeps well when sealed in cans. Upon dilu. it forms a stable, homogeneous suspension that is easy to spray. Better results are obtained at high temps. and low humidity. A daily spraying at 5 p. m. with a 1% dilu. of the concd. product effectively controls mosquitoes. C. R. Fellers

What stimuli guide Anopheles maculipennis in seeking food? P. Van Thiel. *Bull. soc. path. exotique* **30**, 193–203(Feb. 10, 1937); *U. S. Pub. Health Eng. Abstracts* **18**, Ma, 33(Sept. 24, 1938).—Exptl. tests indicate that CO_2 gas is an attractant for female mosquitoes. C. R. F.

Lignin from sorgo residue as source of plastic material (Sorgato) **23**.

Plasticization of polymerized styrene. Arthur J. Warner and Archibald A. New (to International Standard Electric Corp.). Can. 385,103, Nov. 14, 1939. A chemically stable carbocyclic compd. contg. not fewer than 2 and not more than 3 fused rings, b. above 240°C., having a low elec. moment, and capable of swelling polymerized styrene, e. g., 4–20% of phenanthrene, is added to monomeric styrene, and the mixt. polymerized.

Vinylidene chloride plastic derivative. John H. Reilly and Ralph M. Wiley (to Dow Chemical Co.). Can. 385,754, Dec. 19, 1939. A chlorinated diphenyl oxide contg. 3–6 Cl atoms/mol. is dissolved in monomeric vinylidene chloride b. 31.5–32°, and the mixt. subjected to polymerizing conditions. The workability of the polymer is increased at low temps. and the toughness and strength increased by heat-treatment.

Use of zein and formaldehyde to form plastic products. Oswald Sturken (to Corn Products Refining Co.). U. S. 2,178,924, Nov. 7. A mixt. formed at least mainly of zein and CH_2O in aq. soln. is plastified (suitably at 65° for 3–5 min.), molded into desired shapes, and the shaped products are cured, as by heating under pressure.

Molding thermoplastic material such as cellulose acetate compositions. John B. Tegarty (to Sterling Injection Molding, Inc.). U. S. 2,178,410, Oct. 31. Various details of app. and operation suitable for progressive sectional molding of steering-wheel rim covers, etc.

Phosphoric acid esters of nitroalcohols. Byron M. Vanderbilt (to Commercial Solvents Corp.). U. S. 2,177,757, Oct. 31. Tert. esters of phosphoric acid of the general formula: $OP(OCH_2CRR_1NO_2)(OCH_2CR_2R_3NO_2)(CH_2CR_4R_5NO_2)$ where R, R_1, R_2, R_3, R_4 and R_5 represent H or alkyl are produced by a process in which PCl_5 is treated with a primary aliphatic nitro alc., details being given of the production of the tertiary phosphate of 2-methyl-2-nitro-1-propanol, m. 155°, and the tertiary phosphate of 2-methyl-2-nitro-1-butanol, m. 23–5°, suitable for use as a *plasticizer in cellulose ester compns.*

Molding powder. Béla Bártfay. Hung. 121,977, Nov. 2, 1939. Filling materials contg. lignin or protein are treated with the second ingredient of a formaldehyde resin at room temp. or at not above 70°. After impregnation, the product is treated with aq. formaldehyde and dried by an air current at 70°.

Molding powders. V. V. Malyshev, I. D. Abramson and D. L. Bokhan. Russ. 51,858, Sept. 30, 1937. Natural or artificial plastic materials, their solns. or emulsions, with or without plasticizers, fillers and pigments, are atomized in a current of hot air or other gas.

Artificial resins. S. N. Ushakov. Russ. 51,730, Sept. 30, 1937. Phenol-aldehyde resins of the novolac type or their mixts. with polyatomic alcs. are partially etherified or esterified and then condensed with polybasic acids.

Artificial resins. G. S. Petrov. Russ. 51,859, Sept. 30, 1937. Aromatic amines are condensed in two stages with aliphatic aldehydes, in the first stage at a temp. below the b. p. of the aldehyde and without catalysts in the second stage at higher temp. and in the presence of acidic catalysts. The condensation product is washed with water contg. sulfonic acids.

Polyvinyl acetal resins. Geo. O. Morrison and Aubrey F. Price (to Shawinigan Chemicals Ltd.). U. S. 2,179,051, Nov. 7. Substantially colorless polyvinyl resins characterized by a high percentage replacement of hydroxyl groups are produced by a process which involves treating a hydrolysis product of a polyvinyl ester (other than polyvinyl formate) such as polyvinyl acetate with a satd. aliphatic aldehyde contg. at least 2 C atoms in the mol. such as acetaldehyde in the presence of a catalyst such as H_2SO_4 and water, the water being present in an amt. between the min. which will protect the aldehyde and the produced resin from discoloration by the catalyst and the max. compatible with maintaining homogeneous reaction conditions when the acetal reaction exceeds 85%. Several examples are given. Cf. *C. A.* **33**, 9489[9].

Stabilization of a polyvinyl acetal resin. William O. Kenyon and Thomas F. Murray, Jr. (to Canadian Kodak Co., Ltd.). Can. 384,966, Nov. 7, 1939. The stability of a resin prepd. from a polyvinyl alc. and an aldehyde with H_2SO_4 as condensation catalyst is improved by hydrolyzing off, in the presence of HCl, sufficient amts. of the groups that contribute to instability and stopping the hydrolysis before an appreciable amt. of the acetal groups is hydrolyzed off.

High-molecular hydroxylated condensation products from crotonaldehyde. Willi Schmidt, Julius Thewalt and Alexander Rothhaas (to I. G. Farbenind. A.-G.). U. S. 2,178,523, Oct. 31. See Fr. 828,266 (*C. A.* **33**, 2758).

Insulating material for electron discharge tube parts. Russell E. Palmateer (to Hygrade Sylvania Corp.). U. S. 2,179,453, Nov. 7. An oxyacid of N such as HNO_3 is used with powd. Al, Be, Ti or Zr to form a tacky compn., and with an oxide of one of the same metals in uncombined form.

Insulated electrical conductors. David R. Brobst (to Bell Telephone Laboratories, Inc.). U. S. 2,178,365, Oct. 31. An insulation suitable for use on wires, etc., may be formed of cellulose acetate 100, triphenyl phosphate 35, tritolyl phosphate 40 and dimethyl phthalate 40 parts. Such an insulation is flexible and flame-resistant.

Electrical cable insulation. P. N. Gorshkov, P. P. Nikotin, N. A. Chesnokov and G. M. Nodel'man. Russ. 51,970, Oct. 31, 1937. The fire resistance of the insulation is increased by introducing chlorine derivs. of biphenyl and hydrocarbons into natural or synthetic rubber.

Stable adhesive for use on carton flaps, etc. Arthur Bennett. U. S. 2,177,856, Oct. 31. Rubber latex (suitably a latex oxidized with H_2O_2) is given increased adhesiveness under pressure (which adhesiveness is retained for several months on carton flaps or the like) by the addition of a small proportion of Co nitrate.

Adhesive for uniting plies of materials such as those of fir wallboard. Theodore W. Dike and Harry Galber (to I. F. Laucks, Inc.). U. S. 2,178,566, Nov. 7. A semi-fluid aq. alk. oilseed residue proteinous adhesive such as one derived from soybean flour, is used which is substantially free of self flow and has a No. 18 wire MacMichael viscosity between 10 and 90.

Adhesives suitable for use with paper, cloth, metals, etc. Julius G. Little (to Hercules Powder Co.). U. S. 2,179,339, Nov. 7. A pressure-sensitive, nonhardening adhesive compn. consists of a tacky mixt. comprising about 25–80% of a liquid org. hydrogenated abietate such as hydrogenated methyl abietate together with a resin such as hydrogenated rosin which forms at least most of the remainder of the compn.

A cement for uniting paper to glass. Lajos Huszár. Hung. 121,456, Sept. 15, 1939. A mixt. of 500 g. gelatin, 7500 g. water, 750 cc. of 26°Bé. $Ca(ClO_3)_2$ soln. and 100 g. boric acid is specified.

Phosphate esters (frothing, wetting, penetrating, detergent and emulsifying agents) for various uses. Benjamin R. Harris. U. S. 2,177,983, Oct. 31. Numerous examples are given of products, suitable for use in *prepg. chocolate mixts. for coating cakes* and for various other purposes, such as may be produced by bringing into contact a higher fatty acid ester of glycerol having at least one free glycerol hydroxy group and the higher fatty acid radical of which preferably contains 12 or more C atoms in a "pretreatment" stage with P_2O_5 at a temp. of 115° or somewhat higher in a preliminary "conditioning" treatment, without combination of the P_2O_5 with the ester, sepg. the

P_2O_5 and assocd. material, and subsequently effecting phosphatic esterification, as by suitable further treatment with P_2O_5, etc. U. S. 2,177,984 relates to generally similar processes and products, except that in the pretreatment stage of the process the fatty acid glycerol ester material is (instead of treatment with P_2O_5) treated with an alkali metal bisulfate, strong H_2SO_4, SO_3, or pyrosulfuric acid or its acid-reacting salts. Numerous details of the prepn. and use of the products are given.

Alkyl hydroxy aromatic compounds. Lawrence H. Flett (to National Aniline & Chemical Co.). U. S. 2,178,571, Nov. 7. By chlorinating a petroleum distillate, such as kerosene, liquid petrolatum, etc., and condensing the chlorination product with a nuclear hydroxy aromatic compd. and particularly with a nuclear hydroxy aromatic compd. of the benzene series (such as phenol, a cresol, cresylic acid, chlorophenol, salicylic acid, etc.), compds. are obtained which may be employed as intermediates for the production of sulfonation products which are *wetting, detergent, emulsifying*, and other agents. In addn. to their use as intermediate products in the manuf. of the sulfonated compds., the mixts. of alkyl hydroxy aromatic compds. may themselves be employed as detergents, e. g., in the form of solns. of alc.-water mixts. contg. caustic alkali. Also, they may be employed as *insecticides, germicides, parasiticides, or vermicides;* as *wetting agents* in conjunction with emulsifying agents; as *assistants in emulsification;* as *solvents;* as *intermediates for the production of resins* in which phenols are caused to react with resin-forming ingredients of various types; as *plasticizers* for resinous products, cellulose plastics, and other synthetic or natural plastics; and as *intermediates for the production of azo dyes*, for example, azo dyes sol. in org. solvents and (or) useful for the dyeing of cellulose ethers and esters, etc. Numerous examples with details are given, among which is a process which involves chlorinating a kerosene b. 195–300° (mostly 225–275°) and contg. about 5.6% of unsatd. hydrocarbons, to produce a chlorination product contg. mono-, di- and poly-chlorinated hydrocarbons, condensing the resulting chlorination product with a cresol in the presence of $ZnCl_2$ as a condensing agent, to form a mixt. of higher alkyl cresols, and recovering the latter.

Sulfonation of mineral oil extracts. Robert L. Brandt (to Colgate-Palmolive-Peet Co.). U. S. 2,179,174, Nov. 7. An ext. comprising aromatic and other unsatd. constituents such as may be obtained by treating a Texas Gulf Coast oil distillate with a selective solvent such as liquid SO_2 is treated, while in soln. in liquid SO_2, with a sulfonating agent such as a 20% oleum for a time not exceeding 15 min. to obtain a product which may be used as a *detergent* or *wetting* or *emulsifying* agent.

Polymerized alkylolamine derivatives (detergent, emulsifying and flotation agents, etc.). Morris B. Katzman and Albert K. Epstein (to Emulsol Corp.). U. S. 2,178,173, Oct. 31. Compds. suitable for use *in cosmetic emulsions* such as cold creams, etc., which may involve polymerizing alkylolamines at elevated temps. and preferably in the presence of a polymerization catalyst to produce polymers contg. at least 2 N atoms, then treating the resulting polymers with a member of the group consisting of carboxylic acids and alcs. contg. a chain of at least 6 C atoms and derivs. thereof capable of producing esters and ethers to produce esters and ethers of the polymerized alkylolamines and finally treating the resulting product with a substance selected from the group consisting of acid-reacting oxygenated P, oxygenated S and oxygenated B derivatives of alcohols contg. at least 6 C atoms. Various examples and procedure are given. U. S. 2,178,174 relates to products suitable for use in furniture polishes, etc., and which may be obtained by treating an alkylolamine with a higher fatty acid contg. at least 6 C atoms or a deriv. thereof capable of forming esters to produce esters of the alkylolamines, and then treating the resulting product with an acid-reacting substance corresponding to the general formula $(RO)_xXY_w$, where R is an alkyl or acyl radical contg. at least 6 C atoms, X is the residue of an aliphatic polyhydroxy substance, Y is a member selected from the group consisting of oxygenated P, oxygenated S and oxygenated B radicals which is attached to the polyhydroxy substance through an ester linkage, and v and w are small whole numbers. Among the higher mol. wt. carboxylic acids which may be utilized either as such or in the form of derivs. such as acyl halides, esters, particularly triglycerides, anhydrides, etc., for reaction with the alkylolamines to produce esters are the following: caproic, capric, caprylic, hydroaromatic acids such as abietic acid, aromatic acids such as benzoic, benzoylbenzoic, naphthoic, toluic, and naphthenic acids, hydroxystearic acid, higher mol. wt. satd. and unsatd. fatty acids, particularly those derived from natural fats and oils, such as palmitic acid, stearic, lauric, myristic, melissic, oleic, ricinoleic, linoleic or mixed higher fatty acids derived from animal or vegetable fats and fish oils such as lard, oleo oil, coconut oil, corn oil, cottonseed oil, soybean oil, partially or completely hydrogenated vegetable oils such as cottonseed oil, corn oil, sesame oil, and fatty acids of various waxes such as beeswax and carnauba wax. Examples with various procedural details are given.

Aliphatic polyamines. Anderson W. Ralston and Robert J. Vander Wal (to Armour and Co.). U. S. 2,178,522, Oct. 31. Products suitable *for emulsifying oils* and *fats*, use as *lubricants*, as *plasticizing agents* and *modifying agents for resins*, etc., as *detergents*, and in *insecticides* and *fungicides*, are obtained by a process which involves hydrogenating a polymerized nitrile material such as polymerized linseed oil fatty acid nitriles, oleonitrile or stearonitrile. Various examples with details of procedure are given.

Aromatic polyalkylene ethers. Herman A. Bruson (to Rohm & Haas Co.). U. S. 2,178,831, Nov. 7. Compds. such as lauryloxy-, oleyloxy- and cetyloxy-benzene and other compds. of the general formula $A(OC_nH_{2n})_xORA'$ in which A represents an aliphatic or cycloaliphatic hydrocarbon radical, A' represents H or an aliphatic, cycloaliphatic aryl or arylaliphatic hydrocarbon radical, the sum of the aliphatic C atoms in A and A' being at least four, R is an aromatic nucleus, $—C_nH_{2n}—$ is an alkylene group contg. 2–5 C atoms inclusive, and x is an integer from 1 to 5 inclusive, the sulfonation products of which may be used as *wetting agents*, etc., are produced by heating an alc. of the general formula AOH, e. g., lauryl alc., with an aromatic alkylene ether halide of the general formula $A'R(OC_nH_{2n})_xX$, in which X represents a halogen atom, in the presence of an alkali so as to split out alkali metal halide. Various examples with details of procedure are given.

Aromatic polyalkylene ether sulfonates. Herman A. Bruson (to Röhm & Haas Co.). U. S. 2,178,830, Nov. 7. By sulfonation of compds. such a lauryloxyethoxyethoxybenzene, oleyloxyethoxyethoxybenzene, cetyloxyethoxyethoxybenzene and the like, compds. are produced which in the acid form have the general formula $A(OC_nH_{2n})_xOR(A')(SO_3H)_y$ in which A represents an aliphatic or cycloaliphatic hydrocarbon radical, A' represents H or an aliphatic, cycloaliphatic, aryl or arylaliphatic hydrocarbon radical, the sum of the aliphatic C atoms in A and A' being at least four, R is an aromatic nucleus, $—C_nH_{2n}—$ is an alkylene group contg. 2–5 C atoms inclusive, x is an integer from 1 to 5 inclusive and y is one of the integers 1 and 2. Such products may be used as assistants in dyeing, mercerizing, washing, laundering, desizing and sizing operations; in the prepn. of emulsions for spinning and throwing oils, cutting oils, insecticides, finishing compds. contg. waxes and oils; for dispersing pigments and dyes for rubber, inks and leather finishes; in cleaning operations for windows, floors, walls; removing residues of insecticide sprays from fruit, deinking of newsprint, removing dust from the air in air-conditioning systems; in plating baths for deposition of Ni, Sn, Cr, Cd and other metals to give bright deposits and prevent pinholeing; as wetting or spreading agents for insecticides, parasiticides, fungicides, and pest repellents on plants, animals, fabrics, wood; for increasing the absorptive power of paper towels and cotton; and for breaking petroleum emulsions. These compds. also have a fungicidal and bactericidal action. Numerous examples with details are given.

Sulfonated carboxylic acid esters of alcohol amine de-

rivatives (wetting, cleansing, penetrating, emulsifying, lathering, frothing, flotation, and anti-spattering agents). Albert K. Epstein and Morris Katzman (to Emulsol Corp.). U. S. 2,178,139, Oct. 31. Various details are given of the manuf. and uses of products which are preferably prepd. by treating a lipophile deriv. of an alc. amine, contg. at least one free or esterifiable hydroxy group, with a halo carboxylic acid such as chloroacetic or bromoacetic acid, or with a halo carboxylic acid halide such as chloroacetyl chloride or bromoacetyl bromide, to form a chloroacetate or bromoacetate, and then converting the latter into the sulfonic acid deriv. by reaction with an alkali sulfite. Other halo carboxylic acids or derivs. thereof which may be utilized are those derived from mono-, di- and poly-carboxylic acids including, e. g., iodoacetic acid, α-chloropropionic acid, α-chlorobutyric acid, α-bromocapric acid, chlorosuccinyl chloride, dichlorosuccinyl chloride, chlorosuccinic acid, dichlorosuccinic acid, mono- and di-bromoglutaric acid and the corresponding glutaryl bromides, nitrochlorobenzoyl chlorides, etc. Of particular utility are the haloacetic acids and their halides. Instead of initially producing the lipophile deriv. of the alc. amine and then introducing the sulfo carboxylic acid radical, the lipophile radical may be introduced subsequent to the introduction of the sulfo carboxylic acid radical by reaction preferably with a higher fatty acid halide or other lipophile radical. Thus, e. g., an alc. amine such as triethanolamine may be treated with chloroacetyl chloride in such proportions as to esterify one or more hydroxy groups, however, leaving free at least one hydroxy group. The resulting halogen contg. ester may then be treated with the required amt. of an alkali sulfite in aq. media to replace the halogen group by a sulfonic group. The resulting sulfo carboxylic acid ester of the alc. amine may then be isolated and purified or caused to react in the impure state but in dry form with an equiv. amount of a long chain or higher mol. wt. acyl halide to esterify the remaining free hydroxy group.

Esters derived from isocyclic compounds. Karl Daimler and Carl Platz (to I. G. Farbenind. A.-G.). U. S. 2,179,209, Nov. 7. Products useful as *wetting, cleansing* and *dispersing agents*, etc., in treating textiles, etc., are produced, which have the general formula $R_1{}_nAOR_2COY$, where R_1 is an aliphatic or cycloaliphatic hydrocarbon radical having at least 3 C atoms, *n* is a whole number from 1 to 3, A is an isocyclic ring system from the group consisting of hydrogenated and nonhydrogenated benzene and naphthalene radicals, R_2 is an aliphatic hydrocarbon radical, and Y represents $—OR_3SO_3H$, R_3 standing for an aliphatic, cycloaliphatic or aromatic radical. Various details and examples are given of the production and use of compds. such as the isoöctylphenoxyacetic acid ester of hydroxyethanesulfonic acid (I) and the tetradecylphenoxyacetic acid ester of I.

Tetravalent sulphur compounds of high molecular weight (wetting, penetrating, dispersing and detergent substances). James H. Werntz (to E. I. du Pont de Nemours & Co.). U. S. 2,178,353, Oct. 31. By the reaction of dodecyl methyl sulfide or other dialkyl sulfide with a halogenated aliphatic acid such as chloroacetic acid, and of like reactants, products are obtained such as: chloride of dodecylmethylthetine; dodecylmethylthetine; bromide of benzyloctadecylthetine; chloride of octadecylbenzylthetine; bromide of octadecylethyl-α-lauroylthetine; bromide of octadecylethyl-α-propionylthetine; bromide of dodecylmethyl-α-lauroylthetine; bromide of dodecylmethylthetine; bromide of dodecylmethyl-α-propionylthetine; bromide of dodecylmethyl-β-propionylthetine; bromide of benzyloctadecyl-α-lauroylthetine; and chlorides of a mixt. of C_8 to C_{20} alkylmethylthetines, various details for the production of these and similar compds. being given.

Condensation products (peptizing and dispersing agents). Herman A. Bruson and Clinton W. MacMullen (to Röhm & Haas Co.). U. S. 2,178,829, Nov. 7. Products useful for prepg. dispersions of dyes, pigments, S, ZnO etc., *for prepg. emulsions*, as *assistants in dyeing* and *mercerizing*, as *wetting agents* with alk. media, or as *tanning* or *moth-proofing agents* or *detergents*, are produced by condensing in an acid medium an aldehyde and a sulfonate of an aromatic ether of the general formula ROAX in which R is a sulfonated aromatic radical, A is a bivalent radical contg. at least 2 C atoms between X and the O atom, and X represents a hydroxyl, alkoxy, aryloxy, ester, sulfuric ester or sulfonic acid radical or halogen. Numerous examples are given, including condensation of formaldehyde with a sulfonated *p-tert*-octylphenoxyethyl sulfuric acid ester and similar compds.

Forming sheets of vinylidene chloride polymerization products. Richard S. McClurg and Donald L. Gibb (to Dow Chemical Co.). U. S. 2,176,091, Oct. 17. A preformed sheet of polymeric vinylidene chloride is passed through rolling equipment and repeatedly rolled and cross-rolled until the thickness has been reduced at least 50%, all the operations being carried out at temps. substantially below the softening point of the polymer. The rolled sheet has an ultimate tensile strength at least 25% greater than that of the unrolled sheet, is capable of withstanding at least 20 times as many double bends, and exhibits stretch in accordance with Hooke's law without plastic flow.

Cleaning composition. Frederic L. Bishop, Jr. (to American Window Glass Co.). U. S. 2,179,004, Nov. 7. A compn. suitable for cleaning glass sheets to be used in the manuf. of laminated glass is prepd. by mixing dichloroethyl ether with a small proportion of a chloride of Fe, Mn, Zn, Ca or Na.

Apparatus for preparing cleaning or washing solutions from materials such as granular detergents and water. Robert Behrman. U. S. 2,178,735, Nov. 7. Various structural and operative details.

Artificial elastic compositions. J. Carlier. Belg. 432,957, March 31, 1939. A solution of a polymerized vinyl acetate in an org. solvent is treated with an alginate or an algin obtained from alginic acid extd. from seaweed, or from an algulose.

Composite product of gold leaf, etc., for imprinting or ornamentation of leather, cloth, etc. Donald D. Swift (to M. Swift & Sons, Inc.). U. S. 2,175,492, Oct. 10. A base strip of Al is coated with a wax such as beeswax and then with Au leaf or an electrolytic Au deposit, with an overlying sizing colored, as with yellow ochre, to match the metal, and the product is provided with a paper backing. Various mfg. details are described.

Spray-coating surfaces such as those of laminated board. Arthur M. Howald and Leonard S. Meyer (to Plaskon Co., Inc.). U. S. 2,178,358, Oct. 31. A mixt. of particles of finely divided cellulose such as paper or pulp impregnated with a thermosetting substance such as a formaldehyde-urea compn. is suspended in a volatile nonsolvent liquid such as water and the suspension is used for spray coating and the resulting coating is finished by hot-pressing.

Coating lithographic plates. Wm. H. Wood (to Harris-Seybold-Potter Co.). U. S. 2,179,245, Nov. 7. A coating suitable for Zn or Al plates comprises a water-sol. reaction product of a halogen such as Cl or Br and polyvinyl alc. which may be treated with a light-sensitizing Cr compd.

Apparatus for coating with a plastic film. Edward L. Mack and Earle H. Morse (to Reynolds Research Corp.). Can. 385,484, Dec. 5, 1939. Base material is coated with a film of plastic material by extruding the plastic material onto the base material moving at a rate greater than the rate of extrusion, so that the film is stretched while unsupported and thus increased in length and decreased in thickness before contact with the base material.

Stencil sheets. Henry M. Carscallen. U. S. 2,177,768, Oct. 31. A stencil sheet for mimeotyping, adapted to be used upon an opaque, hard backing sheet, having indicating indicia along at least one margin, is substantially rectangular in shape, of transparent paper-like material, pervious to the passage of ink therethrough, and has a colored coating of wax-like material covering one side of the sheet and bonded thereto, the coating being transparent along at least one margin for the width of the indicia

upon the backing paper, and of lesser transparency over the area of the sheet extending away from the margin.

Sand-blasting stencil sheet. Alfred J. Jennings (to E. I. du Pont de Nemours and Co.). Can. 385,085, Nov. 14, 1939. A compn. consisting of crepe rubber 25, wood flour 20, montan wax 8, clay 25, whiting 15, mercaptobenzothiazole Zn salt 1, ZnO 4, stearic acid 0.5, S 1, and phenyl β-naphthylamine is sheeted, vulcanized, and coated with a compn. of crepe rubber 100, brown factice 20, rosin 10, burgundy pitch 5, pine tar 5, mineral oil 5 and ZnO 10 parts.

Electric switchboard panel. William R. Seigle (to Johns-Manville Corp.). Can. 384,291, Sept. 26, 1939. A panel of Ca aluminate cement and asbestos fibers contains Al stearate in amt. of 2 parts by wt. to 100 parts of the sheet to reduce the moisture-absorptiveness.

Forming fibers of molten mineral materials. Daniel C. Drill (to American Rock Wool Corp.). U. S. 2,178,871, Nov. 7. Various details of app. and operation.

Suspension of light-polarizing particles. Edwin H. Land (to Polaroid Corp.). U. S. 2,178,996, Nov. 7. A vehicle such as cellulose acetate compn. carries a dispersion of minute crystals comprising a sulfate of quinine, quinidine, cinchonine or cinchonidine combined with NH_4I and I.

Preventing caking of hygroscopic materials. Havard L. Keil (to Armour and Co.). U. S. 2,175,083, Oct. 3. Materials such as dry liver concentrate, bile salts, and dried meat extract, are prevented from caking owing to absorption of atm. moisture by admixt. with monostearin or a compd. of similar type in small proportion.

Asbestos yarn suitable for use in brake linings, insulation, etc. Willis A. Gibbons (to U. S. Rubber Products, Inc.). U. S. 2,179,087, Nov. 7. A core of drafted and spun asbestos yarn having a relatively rough irregular surface is provided with a cover of loose asbestos fibers rolled into intimate engagement with the irregular surface.

Accelerating reaction between fluids. Joseph D. Griffin Brit. 507,343, June 14, 1939. The phys. or chem. reaction between a liquid and 1 or more fluids, none of which is a bacterial nutrient, is accelerated by passing the fluids downwardly under pressure through a totally enclosed bacterial filter comprising a permeable mech. support filmed with a culture of microörganisms and carrying in its interstices bacterial growths, and continuously or intermittently supplying to the filter a nutrient, preferably in the form of an aq. soln., for the bacterial mass. App. is described. Phys. reactions described are the heating or cooling of liquid or gas, air-conditioning and the extn. of PhOH from a liquid by a solvent such as C_6H_6. Chem. reactions described are: waste liquid from a rayon plant, contg. Na_2S, $Na_2S_2O_3$ and S in soln. and strongly alk. with Na_2CO_3, is treated in the filter with air to produce Na_2SO_4 and CO_2; a similar result follows from the treatment of Na_2CO_3 with SO_2 and air, or with H_2S, CS_2 and air; if the Na_2CO_3 is replaced with dil. H_2SO_4, the effluent is a more concd. H_2SO_4; ammoniacal liquor treated in the filter with H_2S produces $(NH_4)_2SO_4$; pyrites in finely divided form in H_2O is treated with air to form H_2SO_4; hard water is softened by being passed together with a soln. of lime and soda through the filter, in conjunction with air, CO_2 produced by the bacteria from the nutrient and air causing $CaCO_3$ to be pptd. and insol. colloidal products being flocculated by contact with the bacterial mass.

Fumigating gas. Roger G. Aitken and Charles J. S. Warrington (to Canadian Industries Ltd.). Can. 385,868, Dec. 26, 1939. A fumigating gas is prepd. by treating with an acid a mixt. of an alkali metal or alk. earth metal cyanide with an insol. metal sulfite or an aldehyde-bisulfite compd., e. g., a mixt. of NaCN and $CaSO_3$.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Location of ground water by the radio absorption method. Volker Fritsch. *Gas- u. Wasserfach* 82, 757–63 (1939).—Radio methods for investigating underground water supplies must differentiate between free water and that held in pores and cracks of the water-bearing rocks. Exact knowledge of the cond. of these waters and their effect upon radio waves is necessary. This must be supplemented by geologic, hydrologic and mineralogic knowledge to give usable results. Several radio absorption methods are available which give usable results when measurements are carefully made. R. W. Ryan

Some mineral springs of the eastern Balkans. A. Azmanov. *Trud. Podz. Bogat. i Min. Indust. Bulgarija* 7, 199–209(1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 629.—Chemical examn. of the springs at Beronovo, Varbica, Stara Bela Reka and Geravna (Bulgaria) shows all to contain alkali and S. The most productive is that at Varbica which also contains considerable amts. of NaCl, I, H_2S and CH_4; those at Stara Bela Reka and Geravna are characterized by the presence of alkali bicarbonates and I. Contact with some bituminous formation is inferred. C. A. Silberrad

Mineral spring at Bad Karlsbrunn (Silesia). J. Holluta and W. Herrmann. *Verh. Naturforsch. Ver. Brünn* 69, 14–20(1937)(Pub. 1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 627–8.—The water from the recently bored Norbert spring contains per 100 kg.: Cl 0.3, SO_4 0.031, HPO_4 less than 0.05, HCO_3 84.88, K 0.372, Na 1.651, Li trace, Ca 21.076, Sr 0.195, Ba 0.0037, Mg 2.551, Fe^{II} 1.542, Mn^{II} 0.140, Al 0.313, Th trace, H_2SiO_3 6.361, H_2TiO_3 0.004, free CO_2 207.88 g., org. matter equiv. to 177 mg. $KMnO_4$. The temp. was 7.03° (air 3.25°) pH 6.2, radioactivity 4.8 Mache units; that of the neighboring spring ("under the three beeches") was 5.9 units. C. A. S.

The hot medicinal springs of Budapest. F. Papp. *Z. Hydrol.* 17, 79–282(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 629–30; cf. *C. A.* 33, 2631[1].—A detailed account of 115 hot springs in the neighborhood of Budapest, giving the temp. (varying from 20° to 77°), productivity (totalling 56,800,000 l./day, and varying with the level of the Danube) and compn. They are sulfurous and radioactive, and the chief mineral contents are bicarbonates of Ca and Mg. The probable origin is discussed. C. A. Silberrad

Methods of water analysis. Goldstein and E. Leclerc. *Rev. universelle mines* 15, 589–92(1939).—The fact that, in spite of the enormous no. of water analyses made every day and everywhere, no definitely established method has so far been developed is commented on and ascribed to the variety of constituents in a water, in particular of org. matter. A plan for a generally applied analysis is developed which takes into account an examn. by the senses (odor, taste), phys. and phys.-chem. examn., chem. detn. of anions and cations, detn. of non-electrolytes (SiO_2), gas content and discharges, and of residues, oxidizable matter and hardness. The method of Mohr for the detn. of Cl (in form of chlorides) is recommended and a standard method for its application developed. Max Hartenheim

Simple calculation of the correct carbon dioxide content of natural waters and some practical applications. Joseph Tregl. *Gas- u. Wasserfach* 82, 715–18(1939).—If combined CO_2 is replaced by carbonate hardness and CaO by total hardness in the formula of Tillmans, Hirsch and Heckmann (*C. A.* 25, 1310) for correct CO_2 content (i. e., a CO_2 content that will permit deposition of $CaCO_3$ and formation of a protective layer), the formula becomes "correct CO_2" = [carbonate hardness]^2 × [total hardness]/80. Application of this formula to deacidification of water, consumption of chemicals, and judging the quality of the purified water are illustrated. The formula can be applied at elevated temp. as well as at low temp. R. W. Ryan

Water purification in the principal public distribution

systems in Belgium. L. Jansen. *Rev. universelle mines* 15, 554–62(1939).—The methods used in the waterworks of seven large towns, and the original and final compns. of the water are described in detail. M. Hartenheim

Importance of biological research for drinking water. G. Batta, A. Monoyer and G. van Beneden. *Rev. universelle mines* 15, 568–73(1939).—Certain microscopic organisms which are somewhat more highly developed than the pathogenic microbes are mainly ferruginous bacteria which develop especially in Fe- and Mn-rich waters: *Gallionella ferruginea, Leptothrix ochracea, Leptothrix trichogenes, Crenothrix polyspora, Leptothrix echinata, Leptothrix lopholea, Crenothrix fusca, Bacillus manganicus.* Lacking organic nourishment, the ferruginous bacteria take the energy for their growth by oxidation of Fe and Mn compds. Their presence in water reservoirs is not harmful before deferrization or in the filters where they act as purifying agents; they are harmless to the human organism. If they threaten to clog the filters, as indicated by coloring of the water and a taste of fish or ink, their accumulation must be broken up by washing the filters with H_2O_2-water or adding chloramine to the water. Corrosion of water tanks and pipes is sometimes due to *Vibrio desulfuricans* which uses the O of the sulfate mols. to absorb org. substances, and the resulting sulfides start corrosion. Biol. research into the nature and conditions of life of these microorganisms and filters to be used, and treatments to be applied are discussed. In particular, for *water that is used in the sugar extn. of beets,* SO_2 has the best antiseptic action but has to be added largely in excess due to its rapid oxidation of the sulfites into sulfates. Max Hartenheim

Pure water by a single distillation. A. A. Guntz. *Bull. assoc. diplômés microbiol. faculté pharm. Nancy* No. 18, 24–32(1939).—A sketch is given showing the dimensions of the heating app. previously described (*C. A.* 28, 5907[8]; 30, 8065[2]). The properties of water distd. by various methods and the advantages of the Guntz method are discussed. W. C. Tobie

Preparation of "absolute water" by means of "Allassions." R. Loosjes and W. R. Domingo. *Chem. Weekblad* 36, 835–6(1939); cf. Austerweil, *C. A.* 32, 6375[9].—Results obtained with a com. base exchanger show that the water prepd. is the equiv. of distd. water and is obtained at a price 1/16 of that of com. distd. water. A. H. Krappe

Fluorides in food and drinking water—a comparison of effects of water-ingested vs. food-ingested sodium fluoride. F. J. McClure. *Natl. Inst. Health Bull.* No. 172, 53 pp.(1939).—With growing young rats as the exptl. animal, chronic fluorosis was studied particularly from the standpoint of severity of effects produced by NaF—in quantities equiv. to 22.6, 45.2 and 90.4 p. p. m. of F in the drinking water, ingested in the food, as compared with similar quantities ingested in the drinking water. So far as may be shown by (*a*) the av. daily body gain, (*b*) ash and F content of bones and teeth, (*c*) the appearance of the teeth, and (*d*) the total F retained in the final body wt., there were no noticeable differences which could be attributed to either of the 2 media of fluoride ingestion. Acute toxic effects of NaF ingested in the drinking water at a level of about 180 p. p. m. of F were observed, thus confirming previous observations made at the National Inst. of Health. These acute effects of water-ingested fluorides at certain high levels of intake are not to be confused with conditions and effects accompanying fluoride consumption in drinking waters of mottled-enamel areas. Judging from F-balance studies on growing young rats, the av. total retention of F from NaF may equal 30 to 40% of the intake, at the concns. studied. By far the greater portion of this F is deposited in the bones and teeth. The degree of tooth hypoplasia in the rat is directly correlated with the quantity of F present. It has been suggested that the F content of the bones and teeth of exptl. animals may be developed into a biol. test for effective fluorides in foods as well as a means of indicating a pathol. condition in the affected tissue. Observations on the effects of NaF as fed to young rats include the following: (*a*) there is the suggestion of a stimulating effect of 22.6 p. p. m. of F in the diet, on appetite and perhaps on the daily body gain; (*b*) the stimulating effects of fluorides on water-drinking was again observed; (*c*) NaF at a level equiv. to 45 p. p. m. or more of F in food and water gave evidence of a reduced rate of gain; (*d*) an increase in ash content of bones occurred from NaF ingested at levels equaling 22.6 to 600 p. p. m. of F. With the rat, 0.03 to 0.04% F represents approx. the max. that may be present in the whole tooth and the tooth enamel still retain its normal macroscopic appearance. The quantities of F in a large no. of foods, as reported in the literature, are summarized. Although it is extremely difficult to judge the actual conditions of ingestion, and while pos. statements are not warranted, it would appear that an accumulation of F in the bones of adults living in areas where mottled enamel is endemic may be expected. An accumulation of abnormal and perhaps pathol. quantities of F in the bones of adults living in these areas appears within the realm of probability. Future study of chronic fluorosis requires that emphasis be placed on the localization of F in the organism, particularly in the bones and teeth, which relates directly to the cumulative effects of fluoride ingested. There is a need for more information relative to quantities of fluorides in foods, the toxicity of natural food fluorides as compared with pure inorg. fluorides, the associative factors involved in fluoride absorption and metabolism, and direct information is needed from epidemiological biochem. studies relative to the involvement particularly of bone tissue among the human populations of mottled-enamel areas 89 references. J. A. Kennedy

Fluorine in Florida waters. A. P. Black and T. W. Stearns. *Proc. 11th Ann. Convention, Fla. Sect., Am. Water Works Assoc.* 1937, 5–7; *U. S. Pub. Health Eng. Abstracts* 18, W, 67(May 7, 1938).—Of the 498 municipal or private water samples examd. for F in Fla., 21% contained 0.1 p. p. m. or less; 31% contained 0.1–0.5 p. p. m.; 13% contained 0.5–1.0 p. p. m.; and 35% contained 1.0–3.7 p. p. m. Almost without exception those samples which contained 1.0 or more p. p. m. of fluorides came from deep-seated supplies in the Hawthorn formation located in the southwest section of Fla. C. R. Fellers

Small iron-removal water-treatment plants. J. H. Bass. *Ohio Sanitarian* 2, No. 1, 10–12(1939); *U. S. Pub. Health Eng. Abstracts* 19, W, 77(Aug. 26, 1939).—The com. product "Birm" is a catalytic material which is used in an ordinary pressure filter. The CO_2 content of the raw water should be less than 50 p. p. m. and the pH value should be greater than 6.5 for effective Fe removal. C. R. Fellers

Super- and dechlorination practices in water treatment. A. I. Andrews. *Official Bull. N. Dakota Water and Sewage Works Conf.* 6, No. 7, 9–10(1939); *U. S. Pub. Health Eng. Abstracts* 19, W, 77(Aug. 26, 1939).—Cl added in concns. as high as 12 p. p. m., in a sufficiently long contact period, will completely oxidize the taste-producing substances present in the water. The most successful dechlorinating materials are SO_2, $NaHSO_3$, $Na_2S_2O_3$ and activated C. Water contg. phenols, Fe, *Crenothrix*, H_2S, algae and highly polluted with ind. waste, have all been successfully treated by this method. C. R. Fellers

Hypochlorous acid in the sterilization of water, and particularly in the antialgae treatment of refrigeration water in central stations. A. Grégoire. *Rev. universelle mines* 15, 584–9(1939).—The bactericide and algicide action of HOCl is much faster than that of H_2O_2. In presence of bacteria and putrescent materials it is characterized by O in the nascent state, ClO ions, H ions, and a corresponding formation of HCl. The first two are excellent bactericides and algicides and favor flocculation and pptn. of the suspended matter. The Solvay process is described in full; the HOCl soln. is thereby produced on site by a simple app. from Cl, H_2O and either Na_2CO_3, Mg oxychloride or pure Ca-contg. minerals. Operating results of an installation are shown in curves and diagrams. Max Hartenheim

Sulfuric acid for algae control in cooling water. Russell D. Koons. *Refiner Natural Gasoline Mfr.* 18, 397–8

(1939).—Maintenance, under close supervision, of a pH of 7.9–8.1 in the cooling water, by the addn. of H_2SO_4 retarded the growth of algae in the cooling tower and prevented slime accumulation in the condensers. No scale or corrosion troubles were encountered. The cost of acid was less than the saving in maintainance costs. C. H. B. 1

Effect of prechlorination on the number of bacteria and the alteration of the film in English filters. I. P. Ossadchich. *Microbiology.* (U. S. S. R.) **5**, 831(1936); *U. S. Pub. Health Eng. Abstracts* **18**, W, 50–1(Mar. 26, 1938).—In general, when chlorinated water is treated in slow sand filters the bacterial content of the filtrate increases. Chlorination destroys the film which is normally present and liberates the bacteria. The adsorptive power of the filter is reduced and the bacteria are washed out. The increase of bacteria can be prevented if a residual Cl content not greater than 0.3–.5 p. p. m. is maintained. C. R. F. 2

Influence of temperature on the self-purification of water with special regard to bacteriological content. Karl Viehl. *Z. Hyg. Infektionskrankh.* **122**, 81–102(1939).—According to expts. carried out in the lab. on the self-purification of water at different temp. and aerobic conditions, the cell count was greater the lower the temp. Also in river water observed for 4 yrs. there were more cells in the winter than in the summer in so far as the biol. balance was not destroyed. 48 references. Rachel Brown 3

Bacteriological control of purified waters. J. van Beneden. *Rev. universelle mines* **15**, 574–8(1939).—App., testing solns., methods of investigation and reactions used are given in detail for detn. of tubercle bacilli, typhoid bacillus and other toxic impurities. M. Hartenheim 4

Relation between the number of bacteria and the suspended solids in water. Y. Takabatake. *Nagasaki J. Med. Sci.* **14**, 828(1936); *U. S. Pub. Health Eng. Abstracts* **18**, W, 146(Dec. 3, 1938).—The relation between the observed bacterial contents of filtered and unfiltered water varied with the culture medium used and the temp. of incubation. Bacteria from reservoir water grew best when incubated at low temps., and those assocd. with suspended solids in river water developed better at higher temps. Relations between the bacterial count and the suspended solids content of unfiltered reservoir water are seen more clearly with incubation at 20° than at 37°. C. R. Fellers 5

Experimental investigations for the preparation of water with a definite concentration of silver ions by the electro-oligodynamic method. S. V. Moiseev. *Voprosy Pitaniya* **1938**, No. 4–5, 189–97; *Khim. Referat. Zhur.* **2**, No. 4, 109(1939); cf. *C. A.* **33**, 8360[3].—In his investigations of the patented electro-oligodynamic method for disinfecting large amts. of water M. proved that only d. c. should be used. When Ag water with a high concn. of Ag is obtained (which depends on the current d. and the area of the Ag anode), it should be dild. for disinfecting and preservative purposes. When 11 million intestinal bacteria per 1 cc. were added to Ag solns. they were destroyed immediately in concns. of from 8.53×10^{-5} to 3.16×10^{-6}. At a concn. of Ag of from 8.20×10^{-7} to 1.55×10^{-7}/cc. they were either destroyed completely after 1–3 hrs. or they remained in amts. of 1–2/mg. of the Ag water. W. R. Henn 6

Bioflocculation and contact aeration. E. W. Steel. *Water Works & Sewerage* **85**, 158–61(1938); *U. S. Pub. Health Eng. Abstracts* **18**, S, 66–7(July 9, 1938).—Numerous expts. on various phases of contact aeration of settled sewage show distinct advantages with cost reduction in operation. C. R. Fellers 7

Construction and operation of an active-carbon filter plant at the Buckau-Magdeburg Water Works. Werner Kühne and Erwin Heller. *Gas- u. Wasserfach* **82**, 769–74, 784–8(1939).—Taste and odor are successfully removed from Elbe River water by a new active-carbon filtration plant after the water is treated with $Al_2(SO_4)_3$ and fuller's earth used to remove the smallest particles of ppt. The fuller's earth also removes phenols. Regeneration methods for the active C varied with the adsorbed impurities—under some conditions undesirable tastes and odors were removed by treatment with As-free HCl followed by steaming. Enough steam must be used completely to remove volatile taste- and odor-formers. R. W. Ryan 8

A new material for well filters, "Remanit 1800M." H. Hougardy. *Pumpen- u. Brunnenbau, Bohrtech.* **32**, 773(1936); *U. S. Pub. Health Eng. Abstracts* **18**, W, 148(Dec. 10, 1938).—This substance is a Cr-Mn steel contg. Cr 18, Mn 9, Si 0.4 and C 0.1%. C. R. Fellers 9

Results of filter cleaning with sulfur dioxide at Wheeling, W. Va. A. R. Todd. *Taste and Odor Control J.* 5, No. 3, 1–4(1938); *U. S. Pub. Health Eng. Abstracts* **19**, W, 40 (June 3, 1939).—Samples of filter sand were successfully cleaned with a 3–4% soln. of SO_3. A filter of 2,000,000 gals. capacity was treated with 2550 lb. of SO_2 gas. The water contg. this gas was circulated through the filter for 12 hrs. The filter was washed 7 times and allowed to operate normally through the rewash valve. The filter produced good, clear non-acid water after 12 hrs. The treatment costs only 10–12% as much as replacing old filters. C. R. Fellers 10

Iron removal in a rapid filter. Alfred Schumacher. *Gas- u. Wasserfach* **82**, 733–6, 748–52(1939).—One of the Berlin water sources had high Fe content, not satisfactorily removed by existing rapid sand filters. The progress of Fe removal was studied on a small filter with 6.15 sq. m. surface (diam. about 1.4 m.) with a useful filter depth of about 1700 mm. Tests indicated that the washing method commonly used disturbed the filter sand so greatly that an excessively long period was required again to obtain satisfactory Fe removal. Better results were obtained by a short "pressure wash" requiring about 7 min. which reduced water requirements to 4 cu. m. per sq. m. of filter surface and allowed the active contact material to remain on the sand grains. The expts. indicated that an even deeper filter bed would be desirable. Filter velocities of 4.0 m. per hr. and higher shortened the filter cycle so greatly as to be uneconomic. Filter efficiency was calcd. on the basis of Fe removed; this showed that the top 100 cm. of the filter removed little Fe and the next 300 mm. the bulk of the Fe, except toward the end of the cycle. R. W. Ryan 11

Cell reduction and chemical decomposition in the sand filters of water works. Karl Stundl. *Z. Hyg. Infektionskrankh.* **122**, 1–15(1939).—The processes of cell destruction and purification on sand filters are not clear. According to biol. investigations the Ciliata are of little use in the layer of sand but reduce the nos. of bacteria in the water above the sand and in the sludge. The decompn. by bacteria is dependent on the depth of the filter and the O conditions. A greater activity occurs in shallow than in deeper sand layers after prolonged operation. R. B. 12

Softening municipal water supplies by the zeolite process. Eskel Nordell. *Proc. 11th Ann. Convention, Fla. Sect., Am. Water Works Assoc.* **1937**, 18–30; *U. S. Pub. Health Eng. Abstracts* **18**, W, 67(May 7, 1938); cf. *C. A.* **31**, 1917.—Fifteen advantages of the zeolite process over soda-lime are given. Automatic zeolite water softeners which require no manual operation are now available. Fe and Mn can be removed by natural zeolite but the use of a special Mn zeolite is advised. A new nonsiliceous zeolite known as "Zeo-Karb" is now used to replace the bicarbonates with H. This process liberates CO_2 which is removed by aeration. The Zeo-Karb is regenerated with acid. C. R. Fellers 13

The treatment of industrial water by the Magno process. K. Schilling. *Spinner u. Weber* **57**, No. 34, 84, 86(1939). —A method of filtration is described using a product obtained by fractional heating of natural dolomite mineral and contg. MgO, $MgCO_3$ and $CaCO_3$. L. Schefian 14

Some experience in the factory supervision of the water softener in the light of the lime-soda-water diagram. I. W. Arbatsky. *Wärme* **62**, 302–5(1939); cf. *C. A.* **33**, 4713[8].—One manner of supervision of the water softener consists in removal of the color of phenolphthalein through the addn. of $BaCl_2$. The lime-soda-water diagram is established on 2 principles: (1) the water softening proceeds with the pptn. of insol. materials, (2) the water is characterized not by its hardness or alky. but by the excess or deficiency of lime or soda. Descriptions and illustra- 15

tions of the coördinate systems and axial scales employed are contained as well as typical examples of the vectorial addn. of lime or soda excesses. The inaccuracies of the ordinary methods applied to the water softener are discussed with reference to the diagram. H. Kwart

Prevention of incrustation in municipal and domestic water systems with phosphates. Lawrence Kirk. *Official Bull. N. Dakota Water and Sewage Works Conf.* 6, No. 11, 3(1939); *U. S. Pub. Health Eng. Abstracts* 19, W, 102 (Nov. 4, 1939).—Several of the polyphosphates have good anti-incrusting power. A phosphate mixt. called 918-X was evolved as giving excellent service. This combination of chemicals removes Ca from the system. C. R. F.

The supervision of the water supply [in the textile industry]. R. Boye. *Spinner u. Weber* 75, No. 34, 76, 78, 80 (1939).—The necessity of testing the water supply regularly and chem. methods of examn. are discussed. Leopold Scheflan

The significance and production of suitable water for use in the textile industry. Kehren. *Deut. Textilwirt.* 6, No. 19, 11–12(1939).—Deleterious ingredients in ordinary water and methods of their removal are discussed. Surface water is seldom of proper chem. compn. for all-around use in the textile industry; a deep well is the best source of water for this purpose. Leopold Scheflan

Methods of the conditioning of water in the staple-rayon industry. F. Castner. *Zellwolle u. Deut. Kunstseiden-Ztg.* 5, 231–5, 279–82(1939).—A discussion with illustrations showing various com. installations and processes. Leopold Scheflan

Combating corrosion by water. G. Degrémont. *Rev. universelle mines* 15, 562–8(1939).—On the basis of the electrochem. corrosion theory, the various factors influencing and reducing the aggressiveness of water are discussed. The formation of a protective film is facilitated by presence of $CaCO_3$. A more effective and quicker way to render water less corrosive is by coagulation, usually with Al sulfate; the pH of the water can be lowered by this treatment from 0.1 to 1.0 units, but a neutralizing agent should be used with this treatment to avoid excessive acidification. M. H.

A chemical method for protection of pipes in wells and pipe lines against corrosion by aggressive waters; a new theory of the formation of protective layers in water pipes. Aladár Jendrassik. *Magyar Mérnok- Épitészegylet Kozlonye* 73, 307–20(1939).—To explain the formation in iron pipes of a protective layer of rust and Ca carbonate, it is suggested that the rust layer deposited on the pipe walls has a depolarizing effect; in consequence of this effect the ferrous ions formed in the pipe and the rust layers can bind considerable amts. of CO_2. This explains the sedimentation of $CaCO_3$. The $Fe(HCO_3)_2$ formed diffuses through the rust layer and comes into contact with the oxygen dissolved in the water; CO_2 is freed and $Fe(OH)_3$ ppts. The formation of ferrous compds. was proved by repeated expts. The protection of pipes against aggressive waters is a practical application of the new theory. Chem. agents are introduced into the pipe line to ppt. on the walls a layer, consisting chiefly of $CaCO_3$ and $Fe(OH)_3$. These agents must consist of (1) oxidizing, (2) alk. and (3) lime-contg. materials. The final crust is subsequently formed by the water itself. The iron content of the water reaches its normal value after 7–8 weeks. Recently the method has been applied in pipe lines 550 and 1257 m deep with best results. S. S. de Finály

Destruction of lead pipes. L. W. Haase. *Kleine Mitt. Mitglied. Ver. Wasser-, Boden- u. Lufthyg.* 13, 293 (1937); *U. S. Pub. Health Eng. Abstracts* 19, W, 58 (July 22, 1939).—The soln. of Pb depends upon the presence of O_2, the chem. compn. of the water and the period of contact with water. Sol. plumbates are formed with alkali and alk. earth metals. The destruction of Pb pipes may be caused by chem. action from the outside, by phys. action such as frost and erosion, by stray elec. currents, by reactions which depend upon the compn. of the Pb and are promoted by chem. action from inside or outside the pipe, and by unsuitable laying and use. C. R. Fellers

Fishponds of the high Vogelsberg and their productivity. E. Merker. *Allgem. Forst- u. Jagd-Ztg.* 115, 86–99(1939).—Annual variation in heat content, transmission of light, pH, alky., Ca and Mg contents, Na and K contents, Mg and Fe contents, O_2, and phosphate content of fishponds at 500 meters height are discussed in relation to productivity. J. McAfee

Sanitary installations in tropical colonies and the sewer system of the purifying stations in Elizabethville (Belgian Congo). E. Devroey. *Rev. universelle mines* 15, 641–7 (1939).—The particular importance of offal removal and sewerage in tropical climates is discussed, various tropical installation described in general and that of Elizabethville in detail. M. Hartenheim

Semiplant studies of chemical precipitation of sewage. Edgar Whitbee. *Texas Eng. Expt. Sta., Bull.* No. 45, 33 pp.(1938); *U. S. Pub. Health Eng. Abstracts* 19, S, 66–7(May 27, 1939).—The $FeCl_3$ generator in which the Fe salt was manufd. from Fe turnings and Cl, consumed an av. of 42.8 lbs. of Fe and 223 lbs. of Cl daily to produce 160 lbs. $FeCl_3$. The av. efficiency of conversion of Cl to $FeCl_3$ was 47%. The remainder of the Cl formed HCl, remained as free Cl, or satisfied the Cl demand of the water. Atm. losses were very small. Conclusions: Chem. pptn. will remove 2 kinds of material: those which can be settled, and those which can be coagulated and settled. Strong sewage can be coagulated with a dose of 5.25 grains per gal. of $FeCl_3$. The effluent will be clear and will not cause a nuisance when moderately dild. $FeCl_3$ coagulation of sewage is economically successful only under certain conditions, e. g., when the sewage is dil. and either neutral or only slightly acid in reaction and of low total alky. The process was found uneconomical at Dallas, Tex. C. R. Fellers

Bacteria of the paratyphoid-enteritis group in the sewage of greater Berlin. H. Papenberg. *Dept. Sci. Ind. Research* (Brit.), *Water Pollution Research Summary Current Lit.* 10, No. 8, 282 (1937); *U. S. Pub. Health Eng. Abstracts* 18, S, 17 (Mar. 5, 1938).—Typical *Salmonella schottmülleri* were found in 2 of the 152 samples of Berlin sewage examd. One isolation was made of *B. paratyphosum A* (London). Breslau and Gaertner bacteria were not found. These findings show the desirability of frequent sludge removal to reduce the possibility of enteric infections. C. R. F.

New experiments in ferric chloride generation. Charles D. Yaffe. *Munic. Sanit.* 9, 298–9, 308(1938); *U. S. Pub. Health Eng. Abstracts* 18, S, 109(Dec. 17, 1938); cf. *C. A.* 32, 2785.—$FeCl_3$ was the most economical coagulent to use for pptn. at the El Paso sewage plant. It is prepd. by the action of Cl on Fe. The Cl soln. is introduced into 2 of the generating towers which are filled with Fe turnings. Entering at the bottom, the soln. after contact with the Fe, passes from the tops of the tanks to the bottom of the third tank where addnl. Cl is added when necessary. The $FeCl_3$ thus prepd. passes from the top of this tank into the pre-aeration tank where it is mixed with the sewage. One of the chief troubles encountered is the H_2 which plates out on the Fe and prevents the Cl from coming into contact with the Fe. Again accumulation of fine particles of C, Si and other impurities present in the Fe coat the Fe and prevent it from reacting with the Cl. Various plans were tried for the elimination of the "H_2 binding." The process of producing $FeCl_3$ should be kept sep. and distinct from the treatment problem if best results are to be obtained. C. R. Fellers

Developments in the design of small septic-tank systems. E. A. Hepburn. *Health Bull.* (Melbourne) Jan.–June, 1938, 1463–77; *U. S. Pub. Health Eng. Abstracts* 19, S, 105(Aug. 26, 1939). C. R. Fellers

Sludge digestion and the handling of sludge in small treatment plants. G. F. Catlett. *Proc. 11th Ann. Convention, Fla. Sect., Am. Water Works Assoc.* 1937, 63–9; *U. S. Pub. Health Eng. Abstracts* 18, S, 47(May 14, 1938).—Sludge digestion takes place in 3 steps. The nitrogenous and carbohydrate substances are attacked first, then the more resistant nitrogenous material, and finally the more resistant carbohydrates and fats. Imhoff tanks are more applicable to municipalities, and septic tanks are best for

home use. There are no activated-sludge or chem.-pptn. sewage-treatment plants in Fla. C. R. Fellers

Balance of oxygen in an activated sludge tank. N. A. Baziakina. *State Acad. Communal Economy* (Moscow) **1936**, 40 pp.(English summary); *U. S. Pub. Health Eng. Abstracts* **18**, S, 104(Dec. 10, 1938).—A measured amt. of air was pumped into the tank and the amt. of O_2 used in purification was detd. by analysis of the air leaving the tank. Detns. were made of the amt. of O_2 necessary for the formation of nitrites and nitrates and for the oxidation of org. matter in the activated sludge and sewage and the changes occurring in the biochem. O_2 demand (B. O. D.) of the sewage during purification. It is concluded that the B. O. D. of the sewage, as detd. by the nitrate method with incubation for 20 days, indicates the amt. of material biologically oxidized and that the purification process in an aeration tank may be expressed as the quant. reduction of the B. O. D. at the expense of the O_2 absorbed. At the beginning of the process, some of the constituents of the sewage are absorbed by the activated sludge. Later the adsorbed substances are oxidized and the sludge is regenerated. The efficiency of an activated-sludge tank can only be maintained when all the substances brought in by the sewage are oxidized and the activated sludge is restored to its original state. The rate of oxidation of org. matter decreases as the purification process progresses. The intensity of the aeration of the sewage must vary as the sewage passes through the tank. The rate of the biochem. process of oxidation of the org. matter in the aeration tank with an adequate supply of air dets. the time required for the purification according to the concn. of the sewage and the B. O. D. of the purified liquid. This time cannot be reduced by increasing the intensity of aeration. C. R. Fellers

Activated carbon as a means of controlling odors and sludge stability at the Rockford, Mich., sewage-treatment plant. Kenneth L. Carr. *Taste and Odor Control J.* 5, No. 7, 1–3(1939); *U. S. Pub. Health Eng. Abstracts* **19**, S, 126(Oct. 21, 1939).—The primary settling tanks were the main source of odors. The sludge was unstable. The addn. of 17.8–25 lbs. of activated C per million gals. of sewage reduced odor and stabilized the sludge. C. R. Fellers

Direct measurement of the rate of ground-water flow in pollution studies. Elfreda L. Caldwell and Leland W. Parr. *J. Infectious Diseases* **62**, 259–71(1938); *U. S. Pub. Health Eng. Abstracts* **18**, W, 137(Nov. 26, 1938).—The use of NH_4Cl and subsequent estn. of Cl and NH_3 in soil water was used to det. rate of flow and direction. C. R. Fellers

Subsoil pollution in relation to possible contamination of the ground water from human excreta deposited in experimental latrines. Elfreda L. Caldwell. *J. Infectious Diseases* **62**, 272–92(1938); *U. S. Pub. Health Eng. Abstracts* **18**, W, 138–9(Nov. 26, 1938).—Intestinal organisms in privy vaults and latrines are confined to the depositary except as they are mechanically transported by such agencies as primary fluid flow. Under usual conditions, fecal contamination is limited to a few feet around the vaults. C. R. Fellers

Recuperation of materials in the purification of industrial waste waters. M. Prüss. *Rev. universelle mines* **15**, 630–6; *Gesundh.-Ing.* **62**, 587–90(1939).—The economies which can be derived from a possible recuperation of valuable material from waste water are discussed in general, and a few examples of installations are given (mainly in operation in Germany) where fats, Fe, Cu, and coke and coal slimes are recovered. Max Hartenheim

Purification and disposal of milk wastes. E. A. Hepburn. *Health Bull.* (Melbourne) Jan.–June, **1938**, 1478–90; *U. S. Pub. Health Eng. Abstracts* **19**, S, 103(Aug. 26, 1939).—The vol. of the waste must be dild. as much as possible so as to facilitate oxidation. Septic tanks are unsuitable for preliminary treatment of the wastes, as the high acidity of stale milk wastes prevents the development of the desired organisms. The detention period in the preliminary settlement tanks should be not less than 8 hrs. for a flow tank and 2–4 hrs. for a vertical flow tank. Secondary treatment of the waste may be by means of irrigation, filtration or the activated-sludge process. C. R. Fellers

Utilization of waste waters and waste slimes. A. Heilmann. *Rev. universelle mines* **15**, 636–40(1939).—A no. of (German) clarification plants are discussed where the gas developed in settling tanks is collected and used for industrial purposes. The av. compn. of the gas is CH_4 65–95%, CO_2 5–35%, N 0–6%, H 0–8%, H_2S 0–0.25%. The quantity discharged depends to a large extent on the org. substances contained in the waste waters. The gas possesses, after removal of CO_2, a heating value of 8500 kg.-cal./kg. It is burned in gas engines or mixed with city gas; in the former case, 300–500 l. is consumed for 1 HP hr. Quite recently, it is purified of CO_2 and compressed in steel bombs under 250 atm. for driving automobiles; the bombs are exchanged when empty in gas stations. Max Hartenheim

Chloropicrin as a prewarning gas in ship fumigation. G. C. Sherrard. *U. S. Pub. Health Repts.* **54**, 2297–302(1939). J. A. Kennedy
